It is not enough to support your patients; there must be the most scrupulous care about cleanliness, and it will not do to allow them to be defiled by their urine or alvine dejections. In the curious and interesting narrative which Dr. Stewart has given of his personal experiences in an attack of typhoid fever, he alludes to the disagreeable sensations which the delirious patient suffers from the wet, soiled underclothing in contact with his body, as well as from intense light and loud noise. You can promote this cleanliness of the person and the healthy action of the skin by frequently bathing the entire surface with cold or tepid water containing a little thymol or antiseptic vinegar. These lotions not only keep the patient clean, but they also lower the temperature and diminish that sensation of heat and dryness so painful to fever patients. These antiseptic spongings should be repeated two or three times a day.

As for eschars and ulcerations of the skin, they may be prevented by frequently changing the position of the patient, who must not be allowed to lie all the time on his back; and it is always a good plan, where the patient can afford it, to have the bedclothes upon which he lies made of silk instead of cotton, or else to provide him with a water-bed.

Your attention ought to be called to the condition of the mouth and throat of these patients—a matter of considerable importance. You should urge the attendants several times a day to cleanse the teeth and gums of the sordes which collect upon them, and you must insist that they keep the tongue moist; there is nothing better for this purpose than the alkaline waters of Vichy and Vals. This dryness of the tongue is one reason why it is so hard for the typhoid patient to talk, and you can only rid him of this inconvenience by cleansing applications and gargles.

You have seen the great importance which is placed on disinfecting the stools of typhoid patients. These dejections, beside the contagious principle which they contain, have a marked gangrenous odor, which poisons the room of the patient; there is, then, a double necessity for prompt disinfection. You can accomplish this by allowing the fecal matters to be passed in a vessel containing a certain quantity of a two per cent. solution of the sulphate of zinc, copper, or iron, and in taking care also to cleanse with the same solutions all water-closets receiving these dejections. Lavements—and I speak here only of disinfectant lavements—have also the same object. One of the best and most inoffensive is that recommended by Bouchard, and which consists of a mixture of powdered charcoal in water, in the proportion of two or three spoonfuls to the pint. These lavements cause no trouble, and have the advantage of destroying the nauseous smell of the fecal matters.

You should also examine with great care the urinary functions of your patients. You know, in fact, how frequent is retention of urine in typhoid patients, and that, in consequence of the delirious condition in which they are plunged, they are frequently unable to express their natural wants. You should, then, frequently examine the abdomen, and resort to catherization when you find that the bladder is not thoroughly emptied.

It is not everything to have directed the alimentation of your patient, to have minutely indicated all the pains that should be taken for cleanliness and disinfection; you must also furnish indications no less precise concerning the ventilation of the sick-room. You should choose a room which is well aired and ventilated, and place the bed of the patient in the middle of this room; the bed should be narrow, moderately elevated, and divested of curtains and all canopy, so that the attendants can readily and rapidly wait on the patient. If in your power to do so, you should choose two rooms adjoining each other, so that the patient may alternately be transported from one to the other. You should allow but a modicum of light to enter this room, and no lamp should be kept burning in the night-time. Strong light is painful to the typhoid patient and favors the delirium. But few persons ought to remain in the room; one commonly suffices. Urge on the attendants the importance of keeping silence, and if they must converse, let them do so in an undertone. Stewart, in the narrative of which I have just spoken, dwells much on the painful sensations which he experienced when loud conversation was going on in his room.

Generally, the delirious manifestations do not acquire a high intensity; nevertheless, there are cases in which there exists a veritable delirium of action, and which necessitates forcibly keeping the patient in his bed. It is best in these cases, as far as possible, to accomplish this by the aid of the persons who attend the patient, and not to resort to rigorous measures of restraint, such as the strait-jacket, unless other means fail. By the strangulation which it imposes, by the absolute and continuous dorsal position which it necessitates, by the pressure which it exerts on the thorax—the strait-jacket favors

the visceral congestions so frequent in this fever, and may even be a cause of death, as I have several times witnessed in my hospital service.

Apropos of this typhoid delirium, and without departing at present from the hygienic ground which we now occupy, I cannot too much recommend you to cut the hair of your patients, especially in the case of young females, who are apt to have long, thick hair. This is the more needful where there is much mental disturbance. I have often observed considerable improvement in the delirious manifestations by cutting the hair; and this cannot be much of a sacrifice to patients who reflect that their hair will all fall out during the course of convalescence.

You will, perhaps, think, Gentlemen, that I have gone into too many little details about the hygienic management; but all these points have their importance, and I can affirm that typhoid fever well *nursed* is half cured. The necessity of careful attention to hygiene is exemplified in the difference in mortality which obtains between hospital and private practice; for in our hospitals we are not able, by reason of the peculiar conditions in which we are placed, and especially from want of sufficient nurses, to apply these hygienic rules as thoroughly as we would like. Therefore, I earnestly recommend you in your private practice to attend scrupulously to the minor as well as the major details of hygiene. How many severe typhoid cases have I seen which owed their recovery to these hygienic means alone, and to the faithful services of some friendly attendant—rendered with that devotion and that self-sacrifice which are only to be found in the bosom of the family!

THE OINTMENT OF BOROGLYCERIDE (UNGUENTUM BOROGLYCERIDI).

BY L. WEBSTER FOX, M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE GERMANTOWN HOSPITAL; CLINICAL ASSISTANT, EYE DEPARTMENT, JEFFERSON MEDICAL COLLEGE HOSPITAL, ETC.

THE following remarks, relative to the use of unguentum boroglyceridi in certain ocular diseases, are based on an extended experience of over one year, during which time many cases have been treated. The following is the formula for making the ointment:

℞.—Boroglyceride, 50 per cent. solution in glycerine, ... ℥ij.
Vaseline, ... ℥vj.
Ol. rosæ, ... q.s.—M.

Heat the boroglyceride, and, while hot, add it slowly to the vaseline, stirring constantly until thoroughly mixed. To this formula may be added mydriatics, myotics, and the stronger astringents. I have in my possession samples of the ointment containing atropiæ sulph. gr. iv to ℥j, hyoscyamiæ sulph. gr. ij to ℥j, homatropiæ hydrobrom. gr. ij to ℥j, eserin. sulph. gr. ij to ℥j, cupri sulph. gr. ij to ℥j, aluminis pulv. gr. vj to ℥j, and zinci chlor. gr. ij to ℥j. These samples were prepared by Evans, Druggist, 1104 Chestnut Street, August 1, 1883, and have remained pure and sweet, preserving their consistency, and the power of the suspended drugs unaltered.

The advantage claimed for the ointment over the boroglyceride in solution, in ocular therapeutics, is that it can be more easily applied to the eyes of children by the untrained hand; also, that we have a vehicle in which we can combine two drugs, one having a mydriatic (atropiæ sulph.) as well as an irritating effect on the conjunctiva, the other (boric oxide) astringent qualities. It is the experience of every ophthalmic surgeon that an aqueous solution containing a suspended drug, standing in a warm temperature for several days, soon becomes filled with a fungus. A careful ophthalmic surgeon would hesitate to apply such liquids to an ulcerated cornea, or even where there is conjunctivitis. The continued use of a solution of atropia will often excite an acute conjunctivitis and excessive dryness of the throat or erythema of the face, and in a very few cases marked atropia poisoning. By using the atropia suspended in the boroglyceride ointment, we escape these troubles. The boric oxide, being an astringent, counteracts the irritating properties of the atropia, the vaseline closing the mouths of the canaliculi, thereby preventing the atropia being carried through the lachrymal canal to the throat. The atropia is also, on account of the closure of the mouths of the canals, retained longer in the palpebral sacs, hence a more thorough dilatation of the pupil and paralysis of the ciliary muscle are obtained with a lesser quantity of the drug.

In certain purulent diseases of the eye I prefer the boroglyceride in glycerine.[1] The following ocular troubles respond favorably to the action of the ointment when applied in a quantity about the size of a split-pea every three hours.

1. Ulcers of the cornea when arising from anæmia.

2. Phlyctenular ulcers both of cornea and conjunctiva.

3. Ulcer rodens due to infection, and ramolissement of the cornea due to pressure or exposure.

4. Marginal ulcers of the cornea found in strumous children; here the addition of eserin. sulph. (gr. ij to ℥j) hastens the reparative process.

5. Trephined ulcers (central) in children, and ulcers of the cornea in old individuals, and corneal infiltration with pus.

6. *Not* in abrasions of the cornea after removal of foreign bodies, nor in recent wounds of the cornea or sclerotic, either with or without prolapse of the iris.

7. In astigmatic keratitis; accompanying this affection we have supra- and infra-orbital pain, and at times temporal reflex,[2] either of which is a diagnostic symptom. The addition of atropiæ sulph. (gr. iv to ℥j) renders the action of the ciliary muscle passive, which being the exciting factor, relief is at once experienced. The ametropia must

[1] See THE MEDICAL NEWS, May 26, 1883.
[2] Ibid., March 8, 1884.

be corrected, or the patient will have recurrent attacks.

8. In granular lids of young persons, complicated with pannus, the addition of atropiæ sulph. (gr. iv to ℥j) or of cupri sulph. (gr. ij to ℥j) is of the greatest value when we have the condition known as keratitis trachomatosa present.

9. In blepharitis marginalis, eczema of lids, and conjunctivitis; not, however, when there is excessive lachrymation present in the latter trouble. In these cases, the boroglyceride solution in glycerine (fifty per cent.) is preferable. The glycerine being hygroscopic has an affinity for water, the boric oxide being precipitated at once stimulates the diseased condition to healthy action, and relief soon becomes manifest.

In ophthalmia neonatorum, a fifty per cent. solution of boroglyceride in glycerine is applied every two hours (*ad. lib.*), and an ointment of boroglyceride applied to the margins of the eyelids at night.

When applying the boroglyceride in solution, care must be observed in separating the eyelids; this can be done with lid-retractors. In elevating the lids with the retractors, a pouch is made which can be filled with the solution.

An excellent and cheap retractor may be made of a hairpin; curve the looped end to a right angle with its tines. This instrument is safer than the lid-retractors usually found in the ophthalmic instrument case, and is always at hand.

When the corneæ become hazy or opaline in ophthalmia neonatorum, use the ointment containing eserin. sulph. (gr. ij to ℥j) every two hours; a piece the size of a split-pea is to be applied, in addition to the solution of boroglyceride. By following this mode of treatment, the most troublesome cases are cured in a very few days.

My friend, Dr. D. N. Dennis, who has had extended experience in the use of the drug in the treatment of ophthalmia neonatorum, has very kindly placed at my disposal the clinical notes of one of his cases recently treated in private practice.

"On the the sixth day[1] after birth, a purulent discharge was first noticed; the eyelids were œdematous and swollen. The following treatment was at once instituted. The eyes were thoroughly cleansed with tepid water, and a thirty-five per cent. solution of boroglyceride in glycerine was dropped into each eye every two hours (enough to fill the conjunctival sac). The first noticeable change for the better was about thirty hours after the treatment was commenced. The œdema and swelling had greatly decreased, the pus had lessened in quantity, and the eyes looked in better condition generally. The treatment was continued. After its thorough use for three days, it was found that the purulent character of the pus had changed. The solution was then instilled into the eyes every four hours instead of every two; this was continued for several days, when the discharge of pus entirely stopped, and, with the exception of some redness of the conjunctiva, the eyes were in a healthy condition."

As boroglyceride is a most valuable therapeutic agent in other fields of medicine, I have asked my friend Dr. Granville Faught, who has a large and varied field in which to make investigations, to contribute for the benefit of the general practitioner, especially those physicians living remote from the medical centres and inland, his experience with the drug in general practice.

Dr. Faught writes: "It is now nearly two years since Dr. Fox and I commenced the use of boroglyceride in the wards of the Germantown Hospital. Since resigning my position as resident physician in the above-named institution, I have continued its use not only in private practice, but also in the out-patient department of one of the largest charity dispensaries of this city, and it is on this extended experience we base our remarks. Boroglyceride is a non-crystalline, amber-colored, vitreous substance, insoluble in water and alcohol, but very soluble in glycerine. It is formed by heating sixty-two parts of boracic acid and ninety-two parts of glycerine until it ceases to lose weight, which will be when it has lost about one-third. It appears to be, strictly speaking, a saturated solution of boric oxide in glycerine. The addition of water decomposes it, forming boric acid. In therapeutic measures, it is found most convenient to use a fifty per cent. solution in glycerine, which is of the consistency of honey.

"Experience confirms it as an antiseptic astringent of great value in almost all catarrhal affections. It is a good surgical dressing after the acute inflammatory stage, and its application has been followed by good results in relaxed conditions of the throat, post-nasal catarrhs, and gleety discharges; its addition to poultices keeps them sweet and clean in hot weather, even over long periods. It is of the utmost value in gynecology, and supplies a long-felt want. In such cases it should always be applied upon a cotton or jute tampon and allowed to remain from twelve to twenty-four hours. I have seen them on several occasions remain in the vagina, by accident, nine days or longer, and when removed they were not foul. Lacerated cervices, erosions, subinflammatory uterine disease, and leucorrhœa, all show great improvement from its use. I have frequently seen a single tampon remove a long-standing leucorrhœa. For these applications we have also used solutions containing iodine (gr. xx–xxx to ℥j) and thymol (℈j to ℥j). In pruritus of the vulva or anus, it is the treatment we have used. A friend reports to me the case of a patient of his, whose suffering from genital pruritus was so great as to lead her friends to be anxious for her mental state, in which, after all other forms of treatment had failed, an application of boroglyceride brought instantaneous relief. The addition of quiniæ sulph. (℈j) to ung. boroglyceridi (℥j) is very efficacious in pruritus ani. We have several times given it internally, but have never seen any results which we thought were better than from the use of boracic acid."

1316 Walnut Street, Philadelphia.

[1] I may here state that if the pus makes its appearance the second or third day after birth in large quantity, the case will prove refractory, and is not responsive to mild remedies.

A CONTRIBUTION TO THE THERAPEUTICS OF KAIRIN.

BY JAMES K. CROOK, M.D.,

ASSISTANT IN THE DEPARTMENT OF CLINICAL MEDICINE, NEW YORK POST GRADUATE MEDICAL SCHOOL.

As this drug has but recently made its appearance in the field of clinical medicine, and is comparatively unknown to most practitioners, a brief review of its history will not be inappropriate.

It is well known to chemists that the alkaloid *quinine* contains a very large proportion of hydrogen, and recent investigations have shown that it exists in the quinine molecule in combination with *quinoline*. Taking advantage of this knowledge, Drs. Fischer and König,[1] of Munich, instituted a series of experiments in the hope of finding a body possessed of an action similiar to quinia by a synthesis of its elements. By a variety of combinations (beginning with hydrated quinoline), the chemists have succeeded in producing "kairin," of which the *hydrochloride* ($C_{10}H_{13}$,NO,HCl) is the preparation offered for use. It occurs in the form of a crystalline powder of a bright, grayish-yellow color. It is readily soluble in water, and has a bitter-saline, somewhat aromatic taste, which, however, is very transient.

As far as can be ascertained, kairin was first used clinically by Dr. Wilhelm Fischer,[2] of Berlin. He found that when administered to healthy, robust adults, it exerted no physiological action whatever, and was perfectly indifferent toward the temperature. It caused no untoward symptoms, such as headache, humming in the ears, etc. According to Girat's experiments, the toxic dose ranges between one and two grains to the pound of the weight of the animal. The symptoms of an over-dose are those of heart-failure, viz., weak pulse, cold extremities, cyanosis, etc.

Soon after the discovery of the drug, Dr. Filehne,[3] of Erlangen, made a series of careful experiments with it in various diseases marked by high temperature, including pneumonia, phthisis, septicæmia, typhoid fever, and acute articular rheumatism. As a result of his observations, he found it to be a safe and efficient antipyretic, quick in its action, and not unpleasant in its effects. He recommends its use tentatively, in commencing doses of about seven and a half grains per hour, to adults, for four hours, or until the temperature has fallen to 100° F.; the dose is then lowered to three or four grains, to be again increased when the temperature rises. He states that by carefully experimenting during the first day, the proper dose for each individual may be ascertained, which may be adhered to in the subsequent treatment.

Filehne's recommendations have been carried out by subsequent observers, but in some cases with different results. Seifert,[4] for example, reports two cases of severe pneumonia in which he gave doses of eleven grains on alternate hours. No change in the pulse or temperature was observed, and vomiting ensued in both cases. In another case, the temperature was lowered, but the patient became collapsed and died.

Riegel's[5] results were likewise unfortunate in the treatment of pneumonia with kairin. He found that, although in some cases it lowered the temperature nearly to the normal standard, it rose again almost immediately after the discontinuance of the drug. Besides, no improvement in the subjective symptoms, as described by Filehne, was noticed, and there was frequent tendency to great depression, amounting almost to collapse. He concludes, therefore, that kairin is dangerous in pneumonia, on account of its depressing action, and discountenances its use in asthenic forms of the disease.

On the other hand, we have numerous reports of the beneficent action of the drug. Dr. Sassetzki[6] employed it with good results in a case of typhus fever. It lowered the temperature markedly, but caused no sweating. Dr. Knipping,[7] of Neuwied, gave it with marked success in a case of puerperal pyrexia, in which quinia had failed, and where cold was precluded by the weakness of the patient. He noticed profuse diaphoresis, though there was very little decline in the pulse-rate. It was continued for a week with good results, and the patient recovered. Dr. Paul Guttmann[8] employed kairin in a large number of cases, including a great variety of diseases. His results were largely confirmatory of Filehne's, as were also those of Dr. H. A. Janssens,[9] of Holland.

So far, kairin has received very little notice at the hands of investigators in the United States, although frequent attention has been called to it by the medical press. During the summer of 1883 it was used in six cases of typhoid fever by Dr. George B. Shattuck,[10] of Boston. His results were in the main corroboratory of Filehne's, Knippings's, and Sassetzki's. In his opinion, kairin as an antipyretic may be considered as very efficient, prompt, and reasonably safe in its action, though he is fully sensible of the transitory character of its effects.

Dr. F. W. Draper[11] gave it in two cases of typhoid fever in the Boston City Hospital. He observed the usual antipyretic action of the drug, though little change was manifested in the pulse.

Dr. Thomas A. McBride,[12] of New York, in an interesting communication gives his experience in the use of kairin. He considers it unwise to reduce the temperature below 101° F., as he observed that, when it fell to a lower point, it was more likely to rise rapidly, and, if it did not, signs of collapse would appear (cold extremities, cyanosis, weak heart, etc.). As to the rigors which have been said to be induced by kairin, he considers them nothing more than the *chilly sensations* which usually accompany or succeed rapid exacerbations of temperature. On the

whole, he regards kairin as a "safe and valuable antipyretic."

Though much has been said about the antipyretic action of this drug, no investigations have been made, so far as I can ascertain, of its action as an *antiperiodic*. Following is the history of a case of intermittent fever treated by the writer with kairin.

David C., æt. 5, an inmate of St. Stephen's Home for Children, was first seen about 3 P.M., November 5, 1883. The Sisters of Charity in the institution informed me that the patient had been suffering with severe chills, followed by high fever, on alternate days, for more than two weeks past. Quinia had been given during the first few days, but apparently without effect, and it had been relinquished, none having been given for a week. When seen at this visit the patient was found in the hot stage of a paroxysm of the fever. The temperature was 105½° F., pulse 138, respirations 39 and very superficial. The face was flushed, and there was extreme restlessness.

Patient was seen three hours later, when the "sweating stage" had become established. The surface was bedewed with a profuse perspiration, and the patient was sleeping calmly. The thermometer registered 101½°, and the pulse had fallen twenty-five beats a minute. Physical examination disclosed nothing save the fact that there was considerable emaciation.. It was evidently a typical case of simple intermittent fever of the *tertian* type. Ordered kairin in three-grain doses to be given every two hours, beginning at 7 o'clock the next morning.

November 6, 3.30 P.M.—Has taken four three-grain doses of kairin; seems to be a little dazed and stupefied and disinclined to talk; hands and feet are not quite as warm as natural, but the pulse is strong and regular; skin moist, and urine abundant—presenting the characteristic greenish appearance noticed by Fischer, Filehne, and others; temperature 98°, pulse 110, respirations 22; ordered kairin discontinued for to-day, but to be given in same doses and at same intervals to-morrow, with an occasional tablespoonful of brandy and milk.

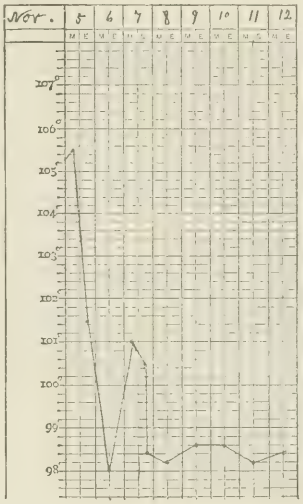
7th, 3.40 P.M.—(Hour for paroxysm). Has had but three three-grain doses of kairin, as the nurse neglected to begin early enough to give four, as ordered. The nurse informs me that the patient has had a slight rigor, which came on about an hour later than usual; the temperature is 101° F., pulse 120, respirations 24. A few herpetic vesicles are noticed about the lips; is bright and communicative, skin moist, and urine still greenish. A dose of kairin (three grains) was given, and the temperature, taken an hour later, was found to have fallen half a degree; defervescence continued until 8 P.M., when the temperature had reached the normal standard.

8th, 3.30 P.M.—Has had five three-grain doses of kairin; pulse, temperature, and respiration are normal; seems to be in good condition; moderate stimulation has been continued; there are no signs of heart-failure; the perspiration is profuse, and the urine is still deeply tinged.

9th, 3 P.M.—Has had five three-grain doses of kairin; temperature 98¾° F., pulse 90, respirations 21; has had no signs of rigor or fever to day; has no headache, and is very cheerful; appetite is returning.

10th.—No change since yesterday; is up and playing about the room, and seems as well as usual.

11th and 12th.—There has been no return of the fever, as shown by the temperature chart; kairin has been continued in diminished doses.



Intermittent fever—tertian type.

January 14, 1884.—There has been no recurrence of the paroxysm of chill and fever, and the patient enjoys his usual health.

In a case of typhoid fever in a boy, æt. 7, kairin was given with good results. The disease had progressed for several days, and during the evening exacerbation the temperature had attained a maximum of 106° before kairin was administered. On the day following this high temperature, eighteen grains of the drug were given (it was given in three-grain doses every two hours at first, but latterly the interval was diminished to one hour). It had the result of keeping the temperature down to 102½° at the height of the evening exacerbation; nor did it rise above this during the remainder of the fever, except on one day, when only two doses of kairin were given, it rose to 104.° It was found necessary to keep the patient constantly under the influence of the drug, as the temperature showed a tendency to rise within a few hours after the last

dose was given. It was found that by carefully observing the case, and employing moderate stimulation, the doses could be repeated almost *ad libitum*, without causing signs of collapse.[1] Kairin was continued for five consecutive days, and the case progressed to a favorable termination.

In a case of acute tuberculosis, with a temperature of 105°, kairin was given with the effect of lowering the temperature to 101°. It seemed to contribute to the comfort of the patient, though apparently without prolonging life, as the case terminated fatally on the eighth day of its administration.

In reviewing the investigations so far made with kairin, we are led to the following conclusions:

1. It is a decided febrifuge, rapid, though somewhat fugacious, in its action.

2. It diminishes the frequency of the heart's action to some extent, though the pulse-rate does not fall *pari passu* with the temperature.

3. The symptoms of collapse—cyanosis, cold extremities, etc.—may be entirely or in a large degree avoided, by close attention and the proper use of stimulants.

4. It is a tolerably constant diaphoretic.

5. Its action in intermittents, though not fully tested, warrants the belief that it possesses valuable antiperiodic properties, and as such should be carefully investigated.

6. Though kairin itself may not be found to possess all the properties of the alkaloid quinia, enough has been learned of its action to justify the hope that a perfect substitute may yet be found, and to inspire us with renewed confidence in the resources of organic chemistry.

A CASE OF COMPLETE TRANSPOSITION OF THE VISCERA, WITH NOTES.[2]

BY JOSEPH EICHBERG, M.D.,

PROFESSOR OF PHYSIOLOGY IN THE MIAMI MEDICAL COLLEGE, CINCINNATI.

IN the month of May of the year 1882 I was requested by Dr. W. H. Taylor to see with him a case of considerable interest, of which he promises to give the clinical features at an early day.

The subject was a young child, about two and a half years old, who presented at the umbilical depression a small opening, through which there passed considerable quantities of a light-yellow fluid. The opening was surrounded by indurated tissue for about one inch in every direction, easily admitted the probe for an inch and a half, and seemed to communicate with a large cavity situated immediately below the abdominal wall. The point of interest to the Doctor, at that time, was to ascertain definitely, if possible, whether the opening was an intestinal fistula, or communicated with any other viscus.

Having obtained a small quantity of the fluid above mentioned, I found, on microscopical examination, that it was composed almost entirely of finely divided fat (the child was subsisting at that time almost exclusively on milk, and received as medicine brandy and cod-liver oil), contained a few starch granules (from some potatoes taken surreptitiously the day before), and a considerable quantity of the large, nucleated columnar epithelium characteristic of the mucous membrane of the intestine. The result of this investigation left no doubt as to the nature of the opening, and a diagnosis of fecal fistula was made. There were circumstances, to be narrated in the clinical history, which rendered a prognosis, sufficiently grave from the nature of this single lesion, extremely unfavorable, and little hope was held out that the child could recover.

Some six or seven weeks after my first visit, I was notified that the child had died, after becoming more and more emaciated, and that the friends had consented to a post-mortem examination. I was obliged to make this at night, by a very indifferent candle-light, so that the results were not perfectly satisfactory. In proceeding in the usual way by making a longitudinal incision through the abdominal wall, I found the intestines matted together and firmly adherent to the parietes about a point corresponding with the artificial opening above mentioned. Careful dissection showed that the opening passed through the wall of the abdomen into an artificial cavity bounded on all sides by the peritoneal coat of adherent coils of the intestine, so that a circumscribed space of about an inch and a half in diameter was formed; this cavity was filled with a fluid of the same nature as that we had obtained during the life of the child. The posterior wall of the cavity, made up, like other parts, of intestinal loops, showed at one point an opening communicating, as we found by tracing down the intestine, with the central portion of the ilium, through which the intestinal contents passed, firstly, into the cavity, and then, through the fistula, to appear externally.

The coils of intestine had so completely filled the field, that I was not a little surprised, on drawing them down to continue my explorations, to find the larger part of the liver in the left hypochondrium, from which the stomach was entirely absent. The further course of the examination soon showed that I had to do with a case of complete transposition of the viscera, all of the internal organs being displaced so as to occupy similar positions on the opposite side of the body. The spleen was found on the right side, the stomach on the right side, the aorta to the right of the vertebral column, the sigmoid flexure on the right, the cæcum and ascending colon on the left side. Owing to the chronic peritonitis which had matted all parts together, to the poor light, and the youth of the child, it was not possible for me to trace the spermatic veins, to note the relations of the kidneys. The lungs and heart had undergone the same change of position; the right lung, as indicated by the presence of its three lobes, and the direction of its bronchus with relation to the trachea, being in the left half of the thorax, the left lung occupying the right side, in which, too, the heart was situated.

As to pathological lesions, there were found numer-

[1] The perspiration was often profuse.

[2] Read before the Cincinnati Medical Society, Jan. 29, 1884.

ous tubercular ulcers of the intestine, each ulcer being surrounded by a secondary crop of tubercles deposited in the subserous lymphatics, several ulcerations extending down to the peritoneal layer, and involving the large as well as the small intestine. The mesenteric glands were very much enlarged and caseous, two of them were almost entirely broken down, so as to constitute small abscesses. The lungs showed at the apex a few patches of lobular pneumonia with atelectasis of adjacent lobules; but no signs of tubercle were discovered here. It is probable that, in the course of the chronic tubercular process, adhesions were formed between several loops of intestine and the anterior abdominal wall; that the inflammatory products thrown out by the inflamed peritoneum, on the one hand, and about the gradually advancing ulceration, on the other, had finally undergone caseation and softening, and had perforated the anterior wall of the abdomen, so that when the tubercular ulcer finally perforated, it found in front of it a cavity, into which its contents were readily emptied, and from which they were constantly discharged. It was interesting to note the comparative absence of lesions in the lungs, the changes above mentioned as occurring there, being of recent date, and the atelectasis easily accounted for by the enfeebled condition of the child, rendering obstruction of the smaller bronchioles likely to occur from deficient expiration. The probable origin of the tubercular infection was to be sought in the enlarged and degenerated mesenteric glands.

I do not know whether the anatomical anomaly was recognized during life, but it is sufficiently important to merit a little attention. I have before met with one case of complete transposition in a living subject, the case being one that is annually presented to members of a class in physical examination at Vienna; and I am informed that Dr. Illowy of this city has a similar case under observation. I should have taken great pleasure in presenting this individual, but I learn that he is temporarily absent from the city. Dr. Illowy, however, assures me that, at an early date, opportunity will be given of showing the case.

Guttmann,[1] in demonstrating a case of transposition of the viscera before the Berlin Medical Society, says that, from more than one hundred cases collected by him, the anomaly is found more frequently in men than in women, the proportion being as two and a half to one; in ninety per cent. it is found in all the organs of the thorax and abdomen; in ten per cent. in the abdomen alone. Simultaneous transposition of the viscera of thorax and abdomen is complete in seventy-five per cent. of all cases. The duration of life is not influenced by this malposition, as more than half of the reported cases reached ages varying from twenty to eighty-four years.

Gruber comments upon seventy-nine cases studied by himself. Of these, seventy-one were cases of general transposition of all thoracic and abdominal viscera; in eight only abdominal. Seventy-eight occurred in human subjects, and one in the horse (Von Baer mentions a case occurring in a chicken). Forty-nine subjects were men, nineteen women. In eleven the sex was not mentioned. In two cases the subjects were fœtuses, twenty were children up to nine years old, two between fifteen and seventeen, and fifty-five adults between twenty and eighty-four years. The same average age was attained by both sexes. The spleen was wanting in three cases, rudimentary in one, divided into two in one, into three in one, and accompanied by accessory spleens in three cases. There was an abnormal position of the kidneys in eight cases; in one case there existed only one kidney; and in one case the spermatic vessels were not transposed.

In regard to the diagnosis of the position of single organs, we may, by percussion, determine the position of the heart, liver, spleen, stomach; and in some cases of the rectum on the right side, and of the ascending colon on the left. We may also determine the position of the œsophagus on the right of the trachea. Further, the slight lateral deviation of the spinal column, which is normally directed to the right (owing, probably, to the direction of the aorta, and not to the individual being right-handed), gives place to a deviation to the left side; though of thirteen reported cases eleven were right-handed. We may also suspect the transposition of the lungs if pectoral fremitus and the bronchial expiratory murmur are heard more clearly on the left than on the right side. Lloyd[1] mentions in addition that, in a case under his observation, the right testicle was lower than the left.

Von Puech[2] relates a case, reported by a physician of Nimes two hundred years ago, which is probably one of the earliest examples noted. In this case—very like our own—the autopsy was made on a child eighteen months old, weakly from its birth, which died from caseation of the mesenteric glands.

That these cases are not only interesting as anatomical anomalies, but may seriously endanger success in operative measures, is shown by the history or a case reported by Baker[3] of a patient suffering from cancerous stricture of the rectum, upon whom the operation of colotomy was performed in the usual way on the left side, without affording any relief. Death ensued on the following day, and the sigmoid flexure was discovered on the right side, the ascending colon being on the left.

Referring again to the etiology of the displacement, we may mention the theory of Von Baer, who attributes it to a deviation of the umbilical vesicle, which precedes in the order of development both the heart and liver. This normally occupies the median line of the body, inclining later a little to the right. Should this deviation, however, incline the vesicle to the left side, transposition of the viscera follows.

Rindfleisch accepts the displacement of the heart as the prime factor in the general transposition, and

[1] Berlin. klin. Woch., 1876.

[1] London Lancet, 1880, vol. i. p. 527.
[2] Gazette Obstetricale, 1878.
[3] British Medical Journal, 1880.

offers, as an explanation of its occurrence, the following theory:

Every column of liquid which flows through an elastic tube under strong pressure experiences a spiral torsion, and the same physical law may be held to apply to the blood-column, which, like other fluids under similar circumstances, communicates its spiral motion to the vessel containing it. The primitive heart-sac, therefore, acts like a twisted cylinder, and, under normal circumstances, the direction of the spiral turn is from left to right, so that the lower extremity of the spire, subsequently to become the apex of the heart, falls to the left. Should, however, the spiral turn assume the other direction, so that the apex falls to the right, the result will be a complete inversion of the non-symmetrical viscera, which are not formed until a subsequent period, and thus splanchnic inversion must follow.

This explanation, purely theoretical as it is, still leaves us in the dark as to the cause of the unnatural deviation of the spiral to the right side, nor is it likely that the solution will soon be forthcoming. Leaving aside the question of primary etiology, it certainly is more in accordance with the general harmony of nature to assume that one of the earliest developed organs should exercise such an influence over the remainder, as to regulate their position by its own, than that the anomaly should affect each of the misplaced organs individually. We know that the circulatory system is one of the first to show itself in the newly formed being; that in the chick, the contractions of the heart are apparent as early as the thirtieth hour of fœtal life (Kölliker), and it is very reasonable to suppose that an anomaly of position, affecting the heart in the early stages of its development, should not remain without influence on the other viscera, whose growth and development are largely dependent upon that very circulation, of which the heart constitutes so important a part.

A NEW MODE OF OPERATING FOR LACERATED PERINEUM.

By A. H. GOELET, M.D.,
of New York.

It may not be out of place to preface the present article with a suggestion which will aid in the prevention of this accident. Much has been said and written on both the prevention and repair of this injury; but in looking over the literature of the subject, the claim of novelty seems justified in both instances.

When the thighs are flexed on the abdomen, as in the usual obstetric position, greater strain is put upon the perineum as the surrounding integument is put upon the stretch; and, conversely, when the thighs are extended the surrounding integument is relaxed, and with it the perineum; which can be demonstrated by the seat of one's breeches in assuming these positions. If this position be maintained from the moment the head impinges forcibly against the perineum until the whole of the fœtus is expelled, aided by well-directed traction backwards, by means of two fingers hooked in the posterior commissure of the vulva, in the intervals between the pains before the head is against the perineum, the great majority of lacerations which now occur will be prevented. I insist upon this position being maintained during the expulsion of the body of the child, because I believe as many lacerations are produced by the shoulders and hips as by the head, if not more. The experienced obstetrician will not need to be cautioned against a too rapid delivery of the body. I do not mean to say that the limbs should be completely straightened out, but extended, and with the knees only slightly flexed.

Should the accident occur, the immediate operation is strongly advocated. The surface is already denuded, there is little pain produced by the introduction of the sutures at this time, and usually no anæsthetic is required. If the sutures be applied in the way to be described, union will take place more readily, and there is little or no risk of septicæmia; there is better chance of restoring the tone and elasticity of the parts and the functions of the sphincter; and, lastly, the operation will be allowed now, but may be refused afterwards, to the detriment of the patient's future health.

In operating immediately after delivery, place the patient in a good light, on her back, with the knees well separated, and, using the silk-worm gut or Lister's carbolized catgut ligature for sutures, with a small, short needle commence introducing them on the vaginal surface, at the termination of the vaginal rent, tying each suture in the vagina as it is introduced, and in this way stitch the torn vaginal edges together up to the point where this line meets the perineal edge of the wound. Then, with interrupted sutures of the same kind or of silver wire, commencing at the bottom of the perineal surface of the wound (making the sutures superficial only) stitch these surfaces together, carefully coaptating the edges, and closing the wound completely at the top, where the two sets of sutures meet. I prefer the silk-worm gut for the internal sutures because they may be left in for an indefinite period, and do not irritate or become absorbed.

In the secondary operation, I agree with Dr. Emmet that the denudation is generally carried too far out, and the attempt is made to make more of a perineum than originally existed. Externally, the denudation should not be carried further than the line of cicatrix of the old perineum. Denude the outer border first, commencing on the left side of the vulva (right of operator), at the upper point of this line; denude a strip around to the same point on the opposite side, taking care to follow the line of cicatrix and not go too far out. As a guide to the limitation of denudation internally (as suggested by Dr. Emmet), hook up with the tenaculum the apex or crest of the rectocele at such a point that, when pulled forwards to the upper angles of the perineal cicatrix, puts the posterior wall of the vagina gently on the stretch. Then remove a strip of mucous membrane from the upper point of the external boundary line on the left side of the vulva to the point on the crest of the rectocele already deter-

mined upon, and from there to the same point on the right of the vulva. The island of mucous membrane surrounded by these lines is then removed.

The next step is the introduction of the sutures, and this is done in the same way as in the primary operation. The vaginal edges of the denuded surface are stitched together with interrupted superficial sutures of silk-worm gut tied in the vagina, taking care to coaptate the edges carefully. The feel to the finger as it is passed in, after these sutures are all tied, is that of the natural slope of the posterior vaginal wall.

There is now left the outer or perineal border to be united, and, after the wound has been thoroughly cleansed, this is done by interrupted superficial sutures from below upwards, using the silver wire or silk-worm gut, and inserting them near enough together to coaptate the edges thoroughly. Eight or ten vaginal sutures are usually required, and six or eight perineal.

The advantages of this over the old method of introducing the sutures are evident. The more complete coaptation of the edges of both vaginal and perineal surfaces possible by this method insures more prompt and perfect union, and prevents the urine or any discharge from the uterus from coming in contact with the raw surfaces, and the catheter need not be used, which is a great desideratum. The rectocele is turned in and covered up by bringing the vaginal edges together in this way, and the posterior vaginal wall is drawn upwards, narrowing the vaginal orifice to its original capacity. In the old method of introducing deep sutures of silver wire, the internal or vaginal edges are but imperfectly coaptated, and as the sutures are tightened the posterior vaginal wall is pulled downwards. This produces a puckering and thinning of the prospective perineum, and by compressing the bloodvessels interferes with the circulation and nutrition of the parts, and tends to prevent good union.

Since March, 1883, when I first operated in this way, I have had perfectly satisfactory results in every case.

The perineal sutures may be removed before the patient leaves the bed, but the vaginal sutures are left in for two or three weeks until the union is sufficiently strong to admit of the necessary amount of dilatation of the vaginal orifice to remove them.

The carbolized catgut sutures, if they do not soften too quickly, may answer for the vagina, and would not require to be removed.

243 West Fifty-fourth Street.

HOSPITAL NOTES.

ORANGE MEMORIAL HOSPITAL, ORANGE, N. J.

(Service of Dr. William Pierson.)

BRONCHOCELE; EXCISION AND RECOVERY.

Reported by James Y. Simpson, M.D., House Surgeon.

Mary F., æt. 20, native of Ireland. Her general health has always been good. Patient has had a swelling at the position of the thyroid gland for twelve years. It has remained small and given her no trouble until a year ago, when it gradually increased in size. During the last seven weeks it has grown very rapidly, and this growth has been accompanied by gradually increasing dyspnœa and dysphagia. The dyspnœa was most marked when she was lying down. She has always had a slight amount of pain in the tumor, but this pain has decidedly increased lately. She has been taking tincture of iodine internally, and having it applied to the skin over the tumor. None of her family have had tumors. Her mother died of consumption and her father of "dropsy."

Condition on Admission.—Admitted October 10, 1883. Patient is well nourished. The thyroid gland is very much enlarged, extending from just below the inferior maxilla to the upper border of the sternum, and laterally beyond the posterior borders of the sterno-mastoid muscles. Patient complains of daily headache, the pain being sharp and throbbing in the frontal region and at the vertex. She has tinnitus aurium, and sleeps very poorly, being often awakened by a smothering feeling. The tumor is the seat of a throbbing pain, and the limbs and joints are often affected in the same way. Patient is also troubled with a cough of five weeks' standing, which is worse at night. While coughing, she expectorates mucus freely, and before her admission to the hospital the sputa have at times been streaked with blood. Palpitation of the heart is marked. Her appetite is poor, and she often has nausea, vomiting, and gastralgia. Her bowels have moved but once in the last month, and this movement occurred two weeks ago. Her heart, lungs, and urine were carefully examined, but no trouble found with them.

Treatment.—Compound licorice powder was ordered to keep the bowels open, and a nutritious diet was given her.

October 12.—Her urine has to be drawn with a catheter. Appetite poor, but she sleeps well.

19th.—Her headache is very severe. She sleeps very little because of dyspnœa. The pain in her neck is quite severe. Her bowels have moved about every other day.

23d.—Symptoms remain about the same, but if any change has occurred, it is for the worse.

25th.—The patient is very anxious to be operated on, notwithstanding she has been told she may die on the table. A consultation was held by the Attending Staff, to decide if an operation was advisable. All the dangers connected with or liable to follow the operation, namely, hemorrhage during the operation, wounding of the pneumogastric or inferior laryngeal nerves, œdema of the glottis, septicæmia, degeneration of the tracheal structures, mental disturbances, and goitrous cachexia, were fully discussed.

It was decided that, in view of increasing headache, dysphagia, dyspnœa, pain—all evidences of injurious pressure on the bloodvessels, nerves, and trachea—it was best to perform thyroidectomy. All of the Staff were of the same opinion. All of the dangers were accurately detailed to the patient, and she still desired the removal of the tumor.

At 11 A.M. the patient was placed upon her back, and the mixture of Billroth—which we always use at this hospital—was administered until complete anæsthesia was produced. This anæsthetic mixture is composed of

ether three parts, chloroform and alcohol each one part.

We have the records of twenty-seven cases in which this was administered, in only two of which vomiting occurred. In all of these cases the patients became anæsthetized more rapidly and remained in a better condition while under its influence than we have ever seen them do with ether.

The operation was performed by Dr. William Pierson, assisted by Drs. Holmes, Chandler, Buttner, and Harvey, of the Attending Staff, and in the presence of a large number of other physicians.

The right anterior jugular vein was ligated with catgut, by passing an aneurism-needle beneath it. This vein was quite prominent as it passed over the tumor, and it was thought best to tie it before making the incisions. An incision was then made in the median line, commencing below the chin and terminating at the upper border of the sternum. Transverse incisions were then made on the sides, so as to intersect the longitudinal incision at right angles. This gave a large, crucial incision, which exposed the tumor. The superficial and deep fasciæ were then divided on a director, the bleeding vessels being secured by artery forceps, which were left in place, excepting some of the veins, which were tied in two places, and then divided between the ligatures. The capsule of the tumor, which was plainly seen, was separated from the surrounding tissues by the fingers. Next, the tumor was lifted from its bed, and the superior and inferior thyroid arteries tied separately, by passing an aneurism-needle beneath them. The capsule of the tumor was then opened, and the tumor enucleated by means of the fingers and scissors. The pedicle of the tumor was next tied in two parts by a double ligature passed through it. The tumor being then excised, the bleeding vessels were tied with catgut, excepting a few which were held by black silk. All of the ligatures—with the exception of those on the thyroid arteries and the pedicle, which were brought out at the extremities of the transverse incision, to assist drainage—were cut short and left in the wound.

The operation was done under strict antiseptic precautions—including the spray—and antiseptic dressings were applied to the wound. The hemorrhage during the operation was not very profuse. The patient did not rally very well from the operation until whiskey was given hypodermatically.

26th.—Morning temperature 99°, pulse 110. Patient is compelled to take nourishment by the rectum, being unable to retain it in her stomach. She coughs a great deal, but expectorates very little. Her urine is drawn with a catheter. Evening temperature 102.4°, pulse 188.

31st.—She has coughed and expectorated freely until to-day. Complains of very little pain, and sleeps and eats well. Dressings removed for the first time. The wound is discharging healthy pus from the drainage openings, and the greater portion of the flaps has healed by primary union. Temperature 98.5°, pulse 78. Can pass her urine.

November 3.—All the sutures but one were removed to-day. The wound is healing rapidly, but the discharge is still free.

7th.—Pulse and temperature normal. Appetite and sleep good. Has no cough. She has a slight amount of pain in the neck. At one angle the wound tends to gape, but is held together with salicylated isinglass-plaster. Discharge is still free.

14th.—Wound is healing rapidly. Discharge is much less.

27th.—Discharge very small in quantity.

December 1.—Allowed to go home. The wound has entirely healed, excepting at two points, where the granulations are very healthy. Patient's appetite is very good, and she sleeps well. Her general condition is excellent. Her cough has about disappeared, and she is feeling well in every respect, and has none of the old symptoms which were prominent before the removal of the tumor.

Report of Examination of Tumor, made by J. W. STICKLER, M.D. The tumor weighed one pound and a quarter. Its shape corresponded with that of a normal thyroid gland. The exterior was quite smooth, save at certain points where there was considerable connective tissue, which had bound the tumor to the skin. Its color was a very dark red. An incision into the interior of the mass on each side of the isthmus revealed numerous small round bodies which were semi-translucent and looked like globules of gelatine collected together. They gave to the surface a shiny and somewhat yellowish appearance. When compression was made, blood oozed from the cut vessels, and flowed quite freely.

Microscopic Examination.—There were some large alveoli having quite dense connective-tissue walls. Many of the alveoli were separated by irregularly placed cells, some of which were granular and deeply colored, while others were in appearance like gelatine. There were also numerous cells within the alveoli which had undergone colloid degeneration, while between them and in the interalveolar spaces there was considerable colloid material, which had a faintly striated appearance. At certain points there were large aggregations of altered cells without any definite arrangement. There were only a few bands of connective tissue, and they were most numerous near the capsule of the tumor. The capsule was not very thick, but was quite dense in structure. Arteries which were tortuous in their course were seen traversing the substance of the tumor.

MEDICAL PROGRESS.

SINUSES TREATED BY SPONGE-GRAFTING.—MR. W. WINSLOW HALL reports a case in which he treated four sinuses in the right forearm by sponge-grafting, other treatment having failed. A strip of fine sponge, one inch and a half by a quarter of an inch, had been soaked in dilute nitro-muriatic acid for twenty-four hours, then washed in water, soaked in carbolic solution for twenty-four hours, and washed a second time in water. This was tied to a piece of thin catgut threaded on a long needle. A director was thrust to the bottom of the sinus; the point of the needle was passed down to the end of the director, and was then brought through the skin. The director was withdrawn, and by pulling on the needle and catgut the sponge-strip was made to fill the sinus from top to bottom. The catgut thread was cut off at the level of the skin, and the wound was dressed with carbolic oil. In three months the arm was entirely well.—*Edinburgh Med. Journal*, March, 1884.

The Diagnostic Value of a Systolic Murmur after Partial Division of an Artery.—In the *St. Petersburg. Med. Wochenschrift*, January 7–19, 1884, Prof. Edward Van Wahl has an interesting paper on this subject. He was led to the investigation of this subject from the satisfactory result of a case of gunshot wound of the thigh, in which the revelation by the stethoscope of a systolic murmur convinced him that the artery had been wounded, and induced him to proceed to tie a ligature on both the central and peripheral ends, as a means of preventing the usual development of such cases. A course of physical investigations by a student of Prof. Wahl, established the fact that when water was conducted through a rubber tube under a pressure of one hundred and ten millimetres of mercury, whether the pressure was constant or subject to pulsations, it always developed a blowing sound, recognizable by the stethoscope, wherever there existed a defect in the tube or a thin spot in its wall. Observation extended to animals whose arteries had been intentionally wounded, gave the same blowing systolic sound when the blood passed out of the opening in the vessel into the surrounding tissue. When the artery, however, was plugged by a thrombus, the sound was of course absent. The importance of this fact can scarcely be overestimated when we reflect how often it happens that the most important symptom of such arterial wounds, bleeding, stops for a while, only to develop later into blood-infiltration, with its consequent associate evils. If, however, the surgeon can satisfy himself that the artery has been wounded, a definite course of action would be immediately suggested. G. Fischer also observed the same phenomenon during the Franco-Prussian war in 1872. In these cases, however, the murmur was not, as it appears, observed until several days after the accident, with a view of obtaining information relative to a primary operation. He supplements his theoretical and historical consideration of the question by three cases: The first published by him in 1881; wound of soft parts, lower third of right thigh, arterial bleeding. One hour after the accident, stethoscope revealed loud systolic murmur, which was recognizable both upwards and downwards in the course of the artery. Ligature of both ends of the artery.

Second case, wound in right upper arm; arterial bleeding. Compression and cold application stopped the bleeding, but on account of pain and swelling he applied for assistance to Wahl's clinic, eight days after the accident. The systolic murmur was distinctly heard in the course of the artery, and the radial pulse was distinctly felt. The diagnosis of a partial division of the artery was made, associated with a commencing hæmatoma, but as no blood had shown itself for eight days, it was thought desirable to allow the wound, which was in a condition of suppuration, to heal before ligating the artery. Bleeding, however, without any apparent cause, set in, and the ligature of the two ends was effected on the following day.

Third case, shot in the left side beneath the clavicle. Profuse bleeding occurred, but stopped, without interference, in half an hour. One hour after the accident he was taken to Wahl's clinic. An extensive infiltration of blood existed in the region of the wound, which was exactly in the course of the subclavian artery. The radial, brachial, and axillary arteries were imperceptible. Severe pain in the fingers and arm. No cough, no vomiting of blood. There was no murmur to be heard with the stethoscope along the course of the artery. The diagnosis was complete division of the subclavian artery. The artery was exposed, and before the clots were removed, the ligatures were placed in situ. After securing the ligatures, the artery was found to have been severed, with the exception of a small piece of tissue about two millimetres wide. The mistakes in diagnosis in this case of a complete division of the artery were due to the absolute occlusion of the artery by means of a blood-clot. This occlusion, however, was only temporary, and had the operation not been undertaken at the time, it would have unquestionably been necessitated later, and under less favorable circumstances. These cases will not fail to show the value of the stethoscope in cases of wounds along the track of the large arteries.—*Weekly Medical Review*, March 1, 1884.

Chloroform Astigmatism.—M. Dubois has made an interesting communication to the Société de Biologie on the action of chloroform on the nutritive media of the eyeball and on the mammary gland. On examining the fundus of dogs narcotized with chloroform, he found its characters unusually difficult, and at times impossible, to distinguish. He observed, also, shadows upon it, which seemed to be produced by a particular alteration of the cornea. Irregular astigmatism was present, and was pronounced. By washing the ocular surface, he proved that these appearances did not depend on mucous flakes in front of the cornea. Similar and very marked astigmatism was observed in a man while under chloroform. This abnormality was found to disappear when sensibility returned. Diminution of refraction was particularly noted in one of the dogs. The tension of the globe was in these various cases also lowered. A comparative observation on the mammæ of a bitch appears to throw some light on the ocular phenomena. The breasts, which were turgid with milk at the commencement of anæsthesia, became flaccid and comparatively empty when the animal was fairly comatose. It may be suggested in accordance with these experiments that the peculiarities of refraction above detailed, like the alterations in the breast, are due to relief of tension in the fluid constituents of the organ affected, a condition which may easily occur during chloroform administration if the heart's action continue vigorous, seeing that every vascular channel then undergoes relaxation of its muscular fibre and consequent dilatation, and the escape of its contents is proportionally facilitated.—*Lancet*, February 16, 1884.

Rupture of the Bladder, Dislocation of the Knee, and Compound Fracture of both Lower Limbs.—Mr. Cottenham Farmer reports the case of a boy, æt. 15 years, who was injured in the above-described manner by a railway train on July 4th. On passing a catheter, about two ounces of bloody urine were drawn off, but without relieving his desire. The catheter was thereupon tied in, under the full impression that grave injury, probably rupture, existed. Further examination was then made, chloroform having been given. There was a compound comminuted fracture of the lower third of the right leg, with loss of blood from the wound, and dislocation at the knee-joint. There

was also a compound and much comminuted fracture of the left leg.

The following treatment was at once adopted. Both wounds were covered with dry absorbent wool, and then the legs, to above the knee, were enveloped in Southall's pads. These were strengthened with soaked millboard splints, and the whole was firmly and evenly bandaged from the toes to above the knee-joints. The dislocation was then reduced. The boy was then carried to bed, and the legs placed in Lawrence's cradle-splints, and these were swung by ropes suspended from the ceiling, so as to insure to the limbs the freest possible movement. Opium was administered during the night, and poultices were applied to the abdomen.

On the 5th, the patient complained only of abdominal pain. There was great tenderness over the pubes. The urine passed through the catheter less tinged with blood. Next day the urine was clear; there was still suprapubic pain. On the 14th, the catheter was withdrawn, and he passed urine freely and with little pain. His legs had never given him the least discomfort; but Mr. Farmer, on the 14th instant, cut open the bandages and exposed the limb. He was astonished at its appearance. It looked quite natural; the wound had healed, nor was there even a trace of ecchymosis; the bones appeared firm and free from pain on pressure. The splints were reapplied on the 20th. Owing to a disagreeable smell, he opened and exposed the left leg, finding the following condition. The limb looked in every way healthy, but on its inner aspect, lying thoroughly exposed, and without the slightest signs of inflammatory action, was a large piece of the tibia (over two and a half inches in length). This he seized and lifted out of its bed, leaving a healthy looking wound, which progressed rapidly towards healing.

On August 16th, both legs were put up in plaster-of-Paris, and the patient left for home. He has since resumed his work.—*British Medical Journal*, March 5, 1884.

THE RECTUM ENDING IN THE MEMBRANOUS PORTION OF THE URETHRA.—DR. WILLIAM CRAIG reports the case of a child, the subject of this malformation. Two days after its birth, it having been discovered that the feces were passed through the urethra, an exploratory incision was made in the region of the anal depression, but no bowel was found. The child died about eighteen days after its birth. The autopsy showed the following condition. Externally the penis, testicles, and scrotum were normal in appearance and development. In the middle line of the perineum, instead of an anus, there was a depression or cul-de-sac of sufficient depth to admit the greater part of the distal phalanx of the little finger. The internal organs were exposed by a crucial incision and inspected *in situ*. Above the pelvis they were normal and healthy. The ascending and transverse colon contained some soft, semi-fluid feculent matter, bright yellow in color. The descending colon and the pelvic organs, including the penis, scrotum, and testicles, were removed *en masse*, and preserved for some weeks in chloral. They were afterwards transferred to strong spirits for a few days to harden. A section was made in the middle line of the penis, bladder, and lower part of the rectum. The bladder wall was slightly hypertrophied. There was no communication between the rectum and the bladder, but in front of the prostate gland the rectum entered the membranous portion of the urethra.—*Edinburgh Medical Journal*, March, 1884.

NEW SURGICAL NEEDLE AND THREAD.—DR. JOHN WARD COUSINS describes a very simple innovation, by which the ordinary steel needle is superseded by converting the end of the wire into a needle. The wire is cut into equal lengths, and each piece is separately reduced by drawing, with the exception of an inch or two at one extremity. The end is then converted into a convenient needle by pointing and burnishing.

This little invention offers several advantages in many surgical applications. The needle is always new and clean, and it can be used only for a limited number of sutures. It requires no preparation or threading, and the continuity of the needle and the ligature prevents the delay in introduction which often occurs with the ordinary needle from kinking or twisting at the eye. The point is always perfect, so that the pain of penetration is considerably reduced. Damaged needles are instruments of torture; and, even in these days of antiseptic surgery, I have found them carefully preserved in pocket-cases ready for any emergency. The chief purpose of this little invention is to prevent unnecessary pain, and to provide a needle with a perfect point, which can be used only in the introduction of eight or ten sutures, and then thrown away for ever. It is, moreover, especially adapted for the immediate surgery of the field of battle.

In his hands, nickelled steel-wire has proved an excellent metallic thread for closing skin-wounds; and, in consequence of its peculiar rigidity, it requires only one turn of the ligature to secure the edges in perfect apposition. It admits also of very easy removal, and this is a great advantage, for the "taking out of the thread is often a more painful operation than its introduction." The single turn of the wire should be made on one side of the wound, over the point of penetration; and then, on dividing the wire, close to the skin on the opposite side, the suture can be withdrawn with great facility.

The surgical needle and thread is manufactured by Messrs. Maw, Son & Thompson, in several convenient sizes, from nickelled steel and silver wire. The steel needles are made both straight and curved; the silver needles are tipped with steel, and flexible, so that they can be bent to any shape, and are thus especially adapted to many plastic operations. To protect the point from accidental injury, each needle is supplied with a shield of fine straw.—*British Medical Journal*, March 1, 1884.

RUPTURE OF LIGAMENTUM PATELLÆ, WITH TRANSVERSE FRACTURE OF THE PATELLA.—MR. M. GARDINER, of the Edinburgh Royal Infirmary, reports the case of a man, æt. 33 years, who, while falling, had tried to recover himself by a backward jerk, but had failed to do so. Trying to rise, he found he was not able, and when set on his legs he could neither walk nor stand without assistance.

On examination, a large, tolerably definite swelling was seen over the knee-cap. Touch proved this to be fluid. The movements of the joint were limited, extension being almost abolished. Fluctuation was also to

be felt on each side of the ligamentum patellæ, but the attachment of that structure could not be defined, and the finger felt as if it could pass right in between tibia and femur. Rupture of the ligament was therefore diagnosticated. Owing to the history, attention was next directed to the patella itself, the patient stating that he thought it was broken. On account of the swelling, the patella could scarcely be defined, and owing to the rupture of the ligament its superficial area did not seem increased. Fracture was therefore only suspected, but not absolutely diagnosticated.

The swelling of the knee and surrounding tissues increased, but finally subsided under the treatment adopted, and on the fourth day the joint had so far returned to its normal state as to allow of a thorough and perfect examination. This proved the suspected fracture to be real.

It is difficult at first sight to account for both rupture and fracture, but the probability is that the backward jerk described by patient ruptured the ligamentum, and that the blow on the floor fractured the patella.—*Edinburgh Medical Journal*, March, 1884.

Ovariotomy on a Child Eight Years Old.—Dr. Duchamp reports a case of ovariotomy successfully performed on a child eight years of age. The left ovary and tube were removed. The pedicle was dropped into the abdominal cavity. The child recovered without accident.—*Archives de Tocologie*, January, 1884.

The Virus of Hydrophobia.—M. Pasteur made an interesting communication to the Paris Academy of Sciences, on February 26th, in relation to canine madness. He stated that the disease could be communicated to a dog by inoculation with fragments of marrow or of nerve taken from a mad dog. He also stated that he had rendered twenty dogs proof against the disease by inoculating them with a modified virus.—*British Medical Journal*, March 1, 1884.

Rupture of the Aorta during Labor; Post-Mortem Delivery.—The following case is reported from the Obstetrical Clinic at Helsingfors. A woman, æt. 38 years, pregnant with her third child, after taking a bath, came to the clinic complaining of cold. Her previous health had been good. Vaginal examination showed that the os was completely dilated. The head was in the first position. The uterine contractions were energetic. Ten minutes afterward the patient suddenly had a violent convulsion, went into a state of collapse, and ceased to breathe. It being evident that the woman was dead, the forceps were quickly applied and the child delivered.

An autopsy of the woman showed that the pericardium was distended with a large quantity of blood. The heart was fatty, and strongly contracted. A little above the sigmoid valves, was found a rupture of the aorta, involving the internal and middle coats. The aortic coat was very thin at the seat of rupture, and there was a small spot of atheroma on the ascending portion of the vessel. Heinricius, the reporter, thinks that the rupture was due to the increased blood-pressure caused by the energetic contractions of the uterus and the abdominal walls. He has not been able to find another case in literature of rupture of the aorta during labor.—*Archives de Tocologie*, January, 1884.

Hypodermatic Injections of Calomel in the Treatment of Syphilis.—It being granted, says Dr. Louis Jullien in a recent note on this subject, that the hypodermatic treatment of syphilis is the preferable method, what mercurial preparation shall we use? While Lewin, of Berlin, and the majority of practitioners have expressed a preference for soluble and easily absorbed preparations (the bichloride and the peptonate of mercury), Scarenzio has recommended the use of calomel, in suspension, as a very manageable preparation. The first experiments of Scarenzio were made in 1864. Now, twenty years after, his method has received new attention.

The formula first used by Scarenzio was:

Calomel, ...	gr. iij–ivss.
Glycerine, ...	♏ xxv.

Smirnoff modified this formula to one part, by weight, of calomel, to ten parts, by weight, of glycerine. At each injection about gr. iij of alcohol were thrown into the cellular tissue; but in feeble and anæmic women only about gr. j was used. Scarenzio still further modified this form by using mucilage: calomel, gr. ¼–ij; powdered gum Arabic, gr. ¼; distilled water, ♏ xv. The needle of the syringe used should measure at least one inch long. This is important, as in women especially, and in men sometimes, a small abscess will form at the end of the track made by the needle, and the inflammation extend up through it.

As to the choice of locality for making the injection, the posterior part of the upper arm is preferable, then the back and the back part of the shoulders. Smirnoff says: 1. The substance injected *between* the skin and the muscles is not exposed to pressure. 2. The integument over the buttocks is so thick and firm that, even if the injection causes inflammation, the small quantity of pus formed will not reach the surface, but will be absorbed. After having chosen some point at which to make the injection, the skin is pinched up and the needle passed under it, but not into the muscular structures.

The effect of the injections, in the treatment of the secondary manifestations, is very quickly seen. All who have used the method of Scarenzio, declare that the period of illness for each syphilitic has been greatly diminished by it. The promptness with which the secondary eruption disappears is greater than with any other remedy.

The action of calomel injections is, according to Smirnoff, much more energetic than that of other remedies. Smirnoff also insists upon the value of this method in the manifestations of the tertiary stage. Pirocchi and Porlezza have already cited the case of gummous syphilis of the brain cured by two injections, and several others of periostitis and osteoscopic pains. Calomel injections are well borne by young children. After the injection of gr. $\frac{9}{13}$, $\frac{7}{11}$, or $\frac{9}{15}$, they do not appear to suffer, and become quiet. In cases of older children injections of from gr. $\frac{9}{10}$ to iij are sufficient to cause the complete disappearance of all manifestations, whether secondary or tertiary.

As to the number of injections, Scarenzio's first views have been proved to be well founded. Gr. vj of calomel are ordinarily sufficient to cause all syphilitic accidents to disappear. This represents four injections of gr. iss,

given two at a time, the interval between the first and second two being three weeks. These four injections will replace all the arsenal of pills, frictions, washes, etc., and the patient only needs the physician once in three weeks.—*Annales de Dermat. et Syphil.*, February, 1884.

Chloroformic Albuminuria.—At the meeting of the Académie de Médecine, on February 12, M. Bouchard read a paper on "Experimental Study of Death after Subcutaneous Injections of Chloroform and Chloroformic Albuminuria." In 1876, M. Bouchard injected ♏xv of chloroform into a rabbit, causing death in about twenty-five minutes. In cases of this kind an intense albuminuria is caused, often accompanied by hæmaturia. This albuminuria may last for twenty-four hours if death does not take place.

Recently M. Bouchard has performed a series of experiments on rabbits, in order to study the subject more fully. If one injects ♏xij of chloroform into the rabbit, albuminuria always follows, and death takes place in three out of four cases. If ♏vij are injected, three out of four cases die; if only ♏iv are injected, about one-half of the cases die; and if only ♏j–iij are injected, death does not occur unless the injection is repeated.

In these cases, dogs also having been used, M. Bouchard has never, at least in those which survived, seen any evidence of gangrene or phlegmon at the point of injection. Histological examination of the kidneys showed congestion and extravasation of blood into the canaliculi, without epithelial lesions. He has been asked whether the albuminuria and death may not be the result of reflex action produced by irritation of the nerves at the seat of the injection. Having divided the sciatic and crural nerves on the same side, he injected the chloroform into the cicatrix at the seat of the wound. The usual results followed. He therefore rejects the reflex theory.

All his experiments go to show that these accidents depend upon poisoning, upon the absorption of the chloroform. This view is confirmed by the fact that the inhalation of air mixed with chloroform vapor causes the intense albuminuria and hæmaturia, although the amount inhaled may be so small that neither anæsthesia nor sleep is produced. But the albuminuria caused by the inhalation is not followed by death; and, on the other hand, the intravenous injection of ♏v of chloroform, dissolved in alcoholized water, though it caused immediate and profound narcosis, with albuminuria and hæmaturia, death did not follow.

This albuminuria, then, seems to depend upon poisoning, whether the poison acts directly upon the elements of the kidneys at the time of elimination, or whether, being carried into the nerve-centres by the blood, it there influences the parts presiding over the nutrition and circulation of the kidney. But why the injections should cause death, and the inhalations and intravenous injections do not, is still unknown.—*Le Progrès Méd.*, February 16, 1884.

Resection of the Stomach.—Dr. Zamboni reports a case of resection of the stomach for carcinoma of the pylorus. The tumor, limited to the pyloric region, was as large as a lemon. A few omental glands and a portion of the vena portæ were the only other structures affected. The patient was in an extremely unfavorable state at the time of the operation. The abdomen was opened by a long median incision. The resected portion included a part of the greater curvature, and the pyloric portion of the stomach. The operation was strictly antiseptic, but the patient died on the seventh day of purulent peritonitis. This is the fifth resection of the stomach performed in Italy, all the cases having terminated fatally.—*Gazz. degli Ospitali*, Feb. 27, 1884.

Therapeutics of the Lochia in Puerperal Affections.—Dr. G. Eustache, in a recent paper in the *Journal des Sciences Médicales de Lille*, 1884, p. 1, says that the therapeutics of the lochia consist in—

1. Avoiding the retention and stoppage of the flow in the uterus, or vagina, or at the vulva. 2. Modifying, by topical applications of liquids, the state of these surfaces, if they are injured. 3. Also modifying secondarily, by the same means, the offensive qualities of the discharge.

From this it is evident that these means should be employed whenever there is any lesion of the genital passages, especially in metritis; and they should be employed as often as possible before the morbid process has invaded the deeper parts, the tubes, ovaries, and peritoneum. To fulfil these indications, the means are: 1. *Ergot*, which, given in small doses, two or three times a day, prevents the retention of the lochia; 2. *Intravaginal injections*, for which he preferably uses a solution of carbolic acid (1 to 100). The irrigations are made morning and evening, one or two being used until the liquid returns clear. 3. *Intrauterine injections*, which should only be used when there are symptoms of metritis. For these Dr. Eustache uses the carbolic solution (1 to 100), at 86° to 89° Fah., and an irrigator holding a quart, to the tube of which he fastens a rubber tube, or an ordinary double-current tube. The tube is carried into the uterus to the depth of two or three inches. The irrigation should occupy from five to ten minutes.—*Revue Méd. Franç. et Etrang.*, February 16, 1884.

Laparo-hysterotomy.—This operation was performed on February 6, by Dr. Luigi Casati, in the hospital at Forlì, upon a woman, æt. 35 years, for carcinoma of the uterus and ovaries. The operation lasted forty minutes. On the fifth day the patient was in excellent condition.—*Gazz. degli Ospitali*, February 20, 1884.

Extrauterine Pregnancy; Laparotomy.—At the meeting of the Académie de Médicine, on December 11, 1883, M. Lannelongue presented two photographs representing two infants removed, by laparotomy, from two women, the subjects of extrauterine pregnancy. The operations were performed by M. Lucas-Championnière, at the Tenon Hospital, on June 6 and August 3, 1883. The first photograph was that of a male child, seventeen and six-tenths inches long, and weighing three and three-quarter pounds. On opening the abdomen of the mother, the child was found in a sea of pus, and already considerably decomposed. This was at the fifth month of pregnancy.

In the second case, the operation was performed at the twenty-sixth month. The fœtus was adherent to the wall of the cyst, and had to be extracted piecemeal. The women recovered without accident.—*Archives de Tocologie*, January, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 22, 1884.

ANTISEPTIC SURGERY IN MILITARY PRACTICE.

THE address of SURGEON-MAJOR GODWIN on "Antiseptic Surgery in its Application to Field-Service," delivered before the Woolwich Military Medical Society, and published in the *British Medical Journal*, February 23, 1884, elicited a most interesting discussion, in which a number of civil practitioners took part, and which may profitably be noticed in connection with a similar discussion which appeared in the *Verhandlungen der Deutscher Naturforscher und Aerzte in Freiburg* Versammlung 56, 1883.

Both the English and German surgeons were agreed, first, that unless in case of great emergency, as, for example, one of hemorrhage, or severe compound fracture, the wound must not be fingered, probed, or manipulated by the surgeons in the front; and, secondly, that the surgeons in the advance line should limit themselves to provisional protection and occlusion of the wound with some form of antiseptic dressing, which, for obvious reasons, must be cheap, simple, portable, and of small bulk, and, if possible, carried by the soldier himself. The first dressings having been applied, further interference in ordinary cases would not be required. In more severe ones, however, the wound would receive definite and more elaborate attention at the field-hospital.

As might naturally be expected, various materials were recommended for the "first field-dressing," but the general sentiment appeared to be in favor of corrosive sublimate and iodoform. Sir Joseph Lister, Maas, and Beck spoke in the highest terms of the bichloride of mercury; and it may interest those surgeons who have not adopted antiseptic precautions in their operations, to learn that the spray and carbolic acid do not constitute so-called Listerism. In regard to the former, Sir Joseph says, "It would not at all break my heart if I were told that I should never be allowed to use the spray again in my life; I am satisfied I could, by other means, get essentially the same results." Discarding, then, the spray, as not being essential to success, and preferring corrosive sublimate to carbolic acid on account of the great volatility of the latter, he thought that rags steeped in a one to one thousand watery solution with glycerine—which renders the sublimate very soluble—and hung up to dry, would constitute a dressing which was easily prepared, must prove efficacious, and would last for any length of time. Despite his faith in corrosive sublimate, he, however, was of the opinion that iodoform, which combines the advantages of being not bulky, portable, and little soluble in the discharges of a wound, was the best agent for the first dressing; and this view was shared by Sir William MacCormac, Deputy Surgeon-General Marston, Lesser, and Kuester. The powder may, as suggested by Lesser, be carried by the soldier in an empty cartridge, around which are wound a bandage, about four yards long, a piece of absorbent lint or cotton, and a three-cornered handkerchief.

While iodoform does possess undoubted merits, it is not an antiseptic in the true sense of the term. Hence, we think that it should be employed as an accessory to a corrosive sublimate dressing. If the preparation of the first dressing were left to us, we would recommend the following, which would make a package that could be readily sewed in the flap or breast of the soldier's coat. A pad of absorbent lint or cotton and a bandage four yards long, which had been soaked in a solution of one part of corrosive sublimate, five parts of common salt, ten parts of glycerine, and one thousand parts of water, and subsequently dried, along with forty grains of iodoform wrapped in waxed paper or rubber tissue, and a triangular bandage, the whole being contained in an impermeable wrap to protect it from dirt and wet. The wound having been sprinkled with the powder, the corrosive pad is secured over it with the bandage, and the handkerchief used as a sling, in the case of injury to an arm.

Prepared in the way mentioned, the chloride of sodium not only promotes the solubility of the mercurial salt, but renders it stable, by preventing its conversion into calomel. Unless this precaution be taken, the ordinary solution, with the addition of a small amount of glycerine, cannot be relied upon to last any length of time, as is asserted by Sir Joseph Lister.

If the dressing is not sewed in the soldier's uniform, it should not be entrusted to him, since Beck states that, in 1870-71, when no such provision was made for its security, all save two soldiers had thrown it away, and Prof. Longmore declares that, in Egypt, the sanitary instructions issued required the dressing to be carried in the left-hand pocket of the trousers, when a large number of the trousers had only one pocket, and that was on the right side and usually too small to contain the packet.

BLEEDING IN PUERPERAL ECLAMPSIA.

In a little volume just issued, Dr. E. Michener urges bloodletting in the treatment of puerperal eclampsia. He has collected all the cases of this disease which have occurred during the present century in an area of about two hundred square miles, Avondale, Chester County, Pa., being the centre of this area. The number of cases is forty-four; but some are reported by non-professional persons, and, therefore, furnish a doubtful basis for comparison and conclusions.

One fact, clearly established by Dr. Michener's statistics, is that eclampsia is much more frequent in recent years, and, like Peter, of Paris, he makes the general disuse of bleeding in pregnancy the chief cause of this greater frequency. Dr. Michener does not seem to have given any consideration to the increase of population as in part explaining the greater number of eclamptic patients.

In one of the forty-four cases collected, the treatment was not known, but as it occurred early in the century, it is quite as probable that depletion was used as that it was not, and this case was fatal; three of them were treated by irregulars, and these cases also died; of course their treatment is not known, and all, therefore, may be thrown aside so far as teaching anything is concerned. Then six are recorded in which bleeding was not done, and five recovered, that is a little over eighty-three per cent. There remain then thirty-four patients, all of whom were bled, and of these twenty-six recovered, and eight died; that is, the mortality was somewhat over twenty-three per cent. But re-examining the record, we find that four did not have, but were only threatened with convulsions, and, therefore, they should not be included. We have then thirty cases of eclampsia treated by bloodletting, and eight of the patients die; that is, the mortality is 26.66 per cent., a result which, compared with that following the non-depletion, is not remarkably encouraging. Such is the brute logic of the figures Dr. Michener has given—an advantage of ten per cent. in favor of not bleeding.

But let us be just to Dr. Michener, for the cases in which bleeding was not done, and which recovered, were mild attacks. And this brings us face to face with the great difficulty in deducing conclusive truths in therapeutics, even from a large number of cases. No two patients are precisely alike in themselves, or in their diseases, and he is the wisest doctor who selects and adapts his remedies to the individual, rather than fixes an unchanging law of treatment for a disease. Bloodletting in the majority of cases of eclampsia is an invaluable remedy, a remedy more likely to be too seldom than too frequently used in these days, but all eclamptic patients are not to be bled, nor all to be bled the same amount. The recent investigations of Charpentier show that more cases recover after moderate, than after free depletion.

Further, the practitioner should not forget that in some cases the anæsthetic is better than the antiphlogistic treatment, and that in all cases in which the latter is pursued the former usefully supplements it. The results from chloroform which Braun had, sixteen cases, all recovering; and those of Chailly, seventeen recoveries out of nineteen; and of Triaire, five out of five; and those which Froger has collected, quoted by Charpentier, only four per cent. of deaths when chloral alone was used, ought to make one cautious in declaring that bleeding is the only salvation for the eclamptic.

THE STREET-CLEANING PROBLEM.

The cost of cleaning the streets and removing the refuse of a city is necessarily expensive, since the material removed possesses but trifling commercial value, and there is, therefore, little inducement to engage in the work of its utilization. The custom that prevails in American cities of spreading out the population over wide areas, causes the extent of street surface to be large in proportion to the population, and the expense of its care relatively great. The generally inferior quality of street paving is another impediment to thorough work, and a cause of the expensiveness of satisfactory cleansing. These are some of the reasons put forth for the inefficiency of street-cleaning operations in most of our cities; but they are evasive, unsatisfactory, and inadmissible.

Clean streets, at whatever legitimate cost, are imperatively demanded in the interests of the health, comfort, and convenience of the people; and no plea or excuse, or any obstacle whatsoever, can safely be permitted to antagonize successfully this important sanitary requirement. There is nothing intricate, puzzling, nor impracticable in the business of street-cleaning; but judging from the loud complaints that have filled the press of the country the past winter, it would seem to be a problem more difficult of solution than the perplexing question of the pacification of the Soudan.

It is a short-sighted policy that permits the streets of a city to be defiled with filth accumulated for months. The annoyance to citizens, the damage to apparel, equipages, and merchandise, not to speak of the far more serious result of injury to health, are consequences which could easily and profitably be averted, if the authorities were capable, honest, and willing, and fully realized the weight of responsibility resting upon them. The season of mud is well-nigh passed, but another, and still more serious and dangerous annoyance, awaits the public. With the advent of spring, under the influence of clear skies and winds, the filthy compound that defiles the public ways and places, will become dried and converted into dust, and be carried in clouds hither and yon, making the atmosphere stifling, and polluting everything with which it comes in contact.

Filth produces and aggravates disease. In the form of dust it is particularly obnoxious. Recent scientific investigations have rendered it probable that the germs of disease are conveyed by its agency. In connection with experimental investigations relating to the etiology of malarial fevers, Dr. Sternberg has observed the fact, that, during the summer months, the mud in the gutters of New Orleans possesses an extraordinary degree of virulence, due to the presence of pathogenetic varieties of bacteria. He remarks, "the more I study this subject, the more probable it seems to me that in this direction lies the explanation of many problems which have puzzled epidemiologists, and that the sanitarians are right in fighting filth as a prime factor in the production of epidemics—a factor of which the *rôle* is easily understood if this view is correct."

In this connection, we cannot refrain from quoting the timely remarks of one of our best scientists, on this homely question. "When we reflect," he writes, "that this is the dried and pulverized dirt and filth of our streets, derived from all kinds of refuse matter, its dangerous qualities may be suspected if they are not clearly obvious. Conveyed by the winds, it is diffused everywhere, and settles upon and adheres to everything. We inhale it, drink it, and eat it with our food. A speck of mud on our bread excites disgust; but who minds the same thing when it is nothing but a little dust? If our food just brought from the market or the provision store be examined with the microscope, it is found to teem with particles of dust, consisting of fine sand, bits of hay and straw, filaments of cotton from old paper and rags, wood fibres, hairs and scurf scales of man and beast, starch grains, spores, etc. Recent investigations render it probable that dust contains the germs of decomposition, gangrene, and contagious diseases."

It is not a fastidious sentiment that clamors for the rigid cleanliness of our streets and public places, but an instinctive disgust for what is offensive and vile; a natural aversion and educated antagonism to that which may be disease-breeding and pestilential, and, therefore, harmful.

In the light of recent knowledge, the responsibility of those charged with the duty of maintaining public cleanliness is more than ever serious, and no effort should be spared in compelling its fullest realization. An indictment at law in the name of the people, against the recalcitrant agents of the city, for maintaining a public nuisance, would establish a useful precedent, and go far towards inaugurating a reform in this badly administered branch of the public service.

ANTIVIVISECTION AGITATION.

In its editorial of March 8, 1884, *The Philadelphia Medical Times* says, in reply to our recent comments on its position as regards the use of animals in research: "That vivisection conducted in a proper manner is recognized by medical science as a legitimate and necessary means of advancing research, and of adding to our store of knowledge." As to this there can be no difference of sentiment. It is legitimate and needful. The society, the *Times* speaks of and for, desires, it says, "to restrict this practice within proper limits." It would be well then, as a preliminary, to show that here in Pennsylvania it has not been so restricted by the kindliness and common sense of the very few persons who in our time have used it.

In fact we deny the cruelty charge which is made by the *Times* when it quotes the anonymous "many who have declared that vivisection is overdone, and is *greatly abused* in this country." We ourselves speak with unusual knowledge when we reply that this allegation is not true. Pray who are the "many?"

But let us agree, for argumentative advance, that restriction is desirable. Have we any now? In the University of Pennsylvania the laboratories for physiology are used by four persons, or at most five, at somewhat long intervals. Students are never alone in the laboratory. Third course students are not permitted to conduct researches and employ animals in aid of these, without the most careful supervision. If they wish to engage in such pursuits, they must apply to the Professor or his Demonstrator, and show that the object in view is desirable, and that they are competent. Printed rules and the constant custom of the laboratory enjoin the use of anæsthetics. Now what more could be desired? In fact the University discourages physiological work by students, and it is therefore uncommon. More has been done by such workers, and some of it

very good work, in the pathological rooms. But this involves nothing worse than inoculations. The restriction is here, also, in wise and thoughtful hands. Can we get anything better by inviting some kindly sentimentalists to legislate for us? To do so is to admit that we have done wrong and need other masters than our consciences.

The *Times* "is authoritatively informed that the *present* movement does not seek to abolish or to interfere with scientific experimentation further than to *urge* that it be done in as humane a manner as possible."[1] If this be all, we do not object much to being urged to do what we now do. If we are asked to go beyond being urged, we are met with three distinct difficulties. If the present movement should result in a Restriction Act, surely no one believes its advocates would be willing to leave its restrictive capacities to the great medical bodies who now control it, or would exclude laymen—or worse, laywomen—in which case we should be in the cheerful situation of our English friends. But if the "*present*" movement be only for restriction, and of course we admit the honesty of the position assumed by the *Times*, who will assure us against a new campaign in the interests of total abolition? "*Anti*" covers a good deal. With the exception of a few gentlemen not profoundly interested, the Society now engaged in a needless task does not consist of material such as invites belief in its moderation. "Abuse and ridicule do not convince," says the *Times*. No, that is true; but what shall we say of the Whitechapel alleys, placarded with sensation chromos by the English Society with aims like those we are now criticising? If Magendie may be quoted on one side, surely these examples of sentiment run mad to brutality may be quoted by us as a reply and a warning.

The *Times* passes lightly over the calumnies with which some prominent men have suffered here among us, but by them at least they are not forgotten; and so far, here and abroad, the abuse has come in most copiously from the antivivisection side, and, as a rule, has been—in this city at least—endured in silence.

To sum up:

We believe that vivisection is not abused in America.

We know that it is sufficiently restricted by the great medical schools which now control it.

We fear to accept legal restraint, not knowing who will administer it. We dread the fate of the British physiologists.

We do not believe the American Society will pause at restraint any more than has been the case in England.

[1] Italics are ours.

ACUTE ARTERITIS CONSECUTIVE TO TYPHOID FEVER.

DR. BARIÉ calls attention, in the *Revue de Médecine*, Nos. 1 and 2, 1884, to acute inflammation of the arteries as a sequel of typhoid fever, and his paper constitutes a valuable supplement to Dr. Keen's Toner Lecture "On the Surgical Complications and Sequels of the Continued Fevers," delivered in 1877. Confining his investigations to the larger arterial trunks, the author finds that the affection is nearly always met with in the lower extremities, the vessels implicated, in the order of their frequency, being the posterior tibial, femoral, dorsal artery of the foot, popliteal, and anterior tibial. As a rule, unilateral and localized on the right side, it appears during convalescence, or when the patient leaves his bed, and is witnessed as frequently after the lighter as after the more severe type of the disease.

From the stand-points of anatomical lesions, clinical evolution, and termination, two varieties of the affection may be distinguished, namely, acute obliterating arteritis and acute parietal arteritis. The first is characterized by embryonal infiltration of all the tunics, with the formation of a secondary thrombus, and invariably terminates in dry gangrene; while the second variety is merely an inflammation without such a clot, and always terminates in recovery without gangrene.

Dr. Barié believes that the two principal factors concerned in the pathogenesis of the affection are, first, local and permanent irritation of the walls of the arteries induced by a special infectious germ, the bacillus typhosus; and, secondly, profound disturbances of vaso-motor innervation, or vaso-motor spasm. With regard to the symptomatology and treatment, there are no new additions to the observations of Dr. Keen.

In connection with this subject it may be mentioned that Vulpian records, in No. 2 of the same journal, an interesting case of right hemiplegia and aphasia, due to thrombosis of the left Sylvian artery during the course of typhoid fever. Examples of a similar nature are recorded by Dr. Landouzky, in his *Thèse d'Agrégation* "Des Paralysies dans les Maladies Aiguës," 1880.

ANÆSTHESIA BY THE MIXED METHOD.

WE have several times called the attention of our readers to the mode of producing the anæsthetic state by the subcutaneous administration of morphine and atropine, followed by the inhalation of chloroform. This "mixed method" has been largely practised by M. Aubert, of Lyons. He has recently addressed a note to the Society of Biology of Paris, reaffirming the advantages of this method. He finds it safer than the administration

of the anæsthetic by itself, but it possesses other important advantages: the stage of excitement is very slight; profound anæsthesia is obtained in about three minutes; vomiting very rarely occurs, either during the anæsthesia or subsequently, and the whole process of inhalation is greatly facilitated.

The method of Aubert has been submitted to the crucial test of experiment by MM. Paul Bert, Morat, and Dastre, who find that the clinical observations are entirely supported by trials on animals. In view of these facts, and the powerful advocacy of Bernard, Nussbaum, and Aubert, abroad, William Warren Greene, Reeve, and others in this country, it is surprising that so little attention has been paid to the method by practical surgeons.

REVIEWS.

The Field of Disease; a Book of Preventive Medicine. By Benjamin Ward Richardson, M.D., LL.D., F.R.S., Fellow of the Royal College of Physicians, etc. 8vo. pp. 737. Philadelphia: Henry C. Lea's Son & Co., 1884.

The author of this book is already well known on this side of the Atlantic through his numerous and able contributions to medical literature, and by his writings upon the more prominent topics of public health and hygiene. The announcement of a treatise by him on the comprehensive subject of preventive medicine has been received with great satisfaction, not only on account of his eminent qualifications for the undertaking, but also by reason of the need of a standard work of this character.

The volume before us, a handsome octavo of nearly eight hundred pages, is a classical production, comprehensive in scope, logical in arrangement, rich in material, sound in doctrine, and instructive in its teachings. Though intended primarily for "the intelligent reading public," the physician will find it to his advantage to consult freely its pages.

The work is divided into three books, which contain a description of natural diseases, acquired diseases, and the origins, causes, and preventions of disease.

In the first book, the author has presented a carefully written description of the general diseases affecting mankind, taking as a basis the classification adopted by the Royal College of Physicians. To render this work intelligible to the general reader, a preliminary chapter has been inserted upon what may be called the attendant conditions of disease, such as fever, inflammation, congestion, etc. For the same reason, a physiological outline of the systems of organs of the body has been prefixed to the description of local diseases. An interesting chapter on diseases from natural accidents concludes the first book.

In the second book, upon acquired diseases, a classification according to causes has been adopted, because it is the more natural course to pursue. The affections have therefore been arranged under the following heads: 1. Diseases induced or acquired from inorganic and organic poisons. 2. Diseases induced or acquired from physical agencies, mechanical and general. 3. Diseases induced or acquired from mental agencies, moral, emotional, and habitual.

The third book, containing a practical summary of the origins, causes, and preventions of disease, is the most useful part of the treatise, because of its practical bearing upon the affairs of every-day life. Only the causes and preventions of the more common diseases, such as yield the ordinary mortalities, are considered, under the belief that "if we could discover the means of preventing these diseases, the whole field of disease would be so reduced there would be little left to be done except to maintain, systematically, the methods of prevention in all their integrity."

The origins and causes of disease are clearly and intelligently discussed under the following heads: 1. Congenital, hereditary, and constitutional origins and causes. 2. Atmospherical or meteorological origins and causes. 3. Parasitical origins and causes. 4. Zymotic origins and causes. 5. Accidental origins and causes. 6. Social and psychical origins and causes. 7. Senile degenerative origins and causes.

In the part devoted to the consideration of the preventions of disease, the subject is discussed in connection with the varieties of origins and causes of disease, because preventive measures naturally group themselves in position by the side of causes. The three grand agencies concerned in the enumeration of measures of prevention are the *personal*, the *municipal* or *local*, and the *central* or *governmental*. In prescribing the rules applicable to the different groups of disease, a classification, according to their agencies, has been uniformly observed. This systematic arrangement is still further amplified by the introduction of subheads, a plan which is exceedingly serviceable for ready reference. The material contained in the concluding chapter, on the preventions of disease, has been most carefully selected, and accurately represents the best knowledge on the subject.

This book, taken as a whole, is the best of its kind that has ever been published. It is scientific, methodical, and practical. The time of its publication is most opportune. The *people* have never taken so great an interest in health questions as at the present time; and, as this work is intended for the public, its usefulness is insured. The physician will also be profited by consulting its pages.

The work of the publishers leaves nothing to be desired.

Traité des Fièvres, Bilieuses et Typhiques des Pays Chauds. Par le Dr. A. Corre. Pp. 567. Paris: 1883.

In this interesting work we have an excellent account of the fevers which prevail in hot countries. The author adheres to the nomenclature familiar to the practitioner of the South and West. Thus he recognizes a "gastric" and a "bilious" fever. These are different from malarial fevers, which form a distinct group. He gives a very full and excellent description of hemorrhagic malarial fever, and a still more elaborate account of the typho-malarial form. Yellow fever receives careful and thorough treatment, and the section on typhoid completes the work.

The strongest part of this treatise is the clinical. Each form of fever is carefully delineated, and its clinical characteristics well defined. The pathological descriptions are less happy and less accurate, although fairly representing the present aspect of the subject. Take it all in all, this is a treatise which may be fairly regarded as excellent, and which can be recommended as worthy of perusal by anyone desiring information on the subject of fevers.

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, March 6, 1884.

THE PRESIDENT R. A. CLEEMANN, M.D., IN THE CHAIR.

DR. PACKARD demonstrated to the Society a new method of applying

AXIS TRACTION

to any ordinary obstetric forceps. The device consisted of two steel hooks arranged to catch in the fenestræ of the blades of the forceps, and terminating in rings through which a wooden handle is to be passed. The handles of the forceps are to be lashed together.

DR. SMITH remarked that Dr. Tarnier's first suggestion was to pass a cord through holes drilled through a widened portion of the blades, at the point at which handles are now attached. The hooks exhibited by Dr. Packard did not draw from the right point, and he thought there would be difficulty in adapting them when the head was high up.

DR. GOODELL thought that Tarnier was anticipated in the cord attachment by another French physician.

DR. B. F. BAER read a paper on

THE SIGNIFICANCE OF METRORRHAGIA ABOUT AND AFTER THE MENOPAUSE.

Metrorrhagia recurring about the menopause is as likely to be the result of disease of the uterus or its appendages as it is at any period previous to that time. The popular belief that floodings at the change of life are physiological, often results in harm. That the blood-loss is depuratory or critical, and that it protects the vital organs from injurious congestion, is erroneous. Where health exists the cessation of menstruation will be attended by no more aberration of function than is seen in its establishment. An analysis of twenty-two hundred cases treated in hospital and private practice, shows that nearly the same number of women sought advice during the establishment and the decline of menstruation, and it further shows that the numbers rapidly increase as the period of greatest fecundity is reached, and decline after it is past.

Epithelioma of the cervix may result from injury of that organ, but also requires some peculiarity in the structure of the tissues, which renders them susceptible to an induced dyscrasia. When a woman in the midst of the fertile period suddenly ceases to bear children, there is often some local cause for it. There is some causative relation between acquired sterility and cancer. It is safer to believe the disease of local origin, for we will then endeavor to discover and remove all sources of irritation and possibly prevent its development. Detailed histories of a number of cases are given to illustrate the truth of the positions assumed. Where the menopause is retarded beyond the usual period, the cause can often be found in some diseased condition connected with the sexual system, and as a rule it is an old standing trouble. When metrorrhagia recurs after the menopause has been fully established, it is almost invariably the result of a pathological change in the tissues of the uterus.

DR. GOODELL agreed almost wholly with what Dr. Baer had said; he thought the dangers of the menopause much overrated. Cancer and fibroids of the uterus occur more frequently at that age than any other, and have caused the popular dread. Although hemorrhage is always pathological, its cause cannot always be discovered, and in this dodging period serious hemorrhage may occur and no dangerous condition exist. He would like to believe that cancerous growths had a benign incipiency, but cannot go so far. The microscopists make many mistakes in ascribing malignancy to growths removed from the uterus. Dr. Goodell then gave a number of cases in which experienced microscopists had given prognosis of early fatal termination, based upon the cell formation of growths removed from the uterus, but these cases had recovered and now showed no evidence of any diseased condition. With regard to the small proportion of cancerous growths following laceration of the cervix uteri, the Doctor called attention to the large number of Irishmen using clay pipes, and the small number of lip-cancers, and yet it is universally acknowledged that the use of a clay pipe is the principal cause of such growths. Bloodletting is practised very freely in Turkey and the East; and as a consequence women get very stout; such are more liable to profuse hemorrhage at the dodging period.

DR. WILLIAM T. TAYLOR reported a case of

MALARIAL POISONING IN A NEW-BORN BABE.

We have frequently observed fevers of a malarial type in very young children, in some even during the first year, which were ushered in by a convulsion or other prodrome, without a rigor, as occurs in older persons, and their character is only recognized by a repetition of the attack in a day or two. But the youngest subject of this disease which I have met with is the following case.

Mrs. A. R., during her second pregnancy was affected with malarial fever, and, although she was then residing at the sea-shore, was obliged to take occasional doses of quinine to control it. She returned to her city residence at the end of the season, but continued using quinine from time to time until the end of her utero-gestation, which was completed in November last, when her babe was born. Her labor was natural and easy, and she had no unfavorable symptoms. The child appeared healthy, was of good color, but was smaller and feebler than her first-born at its birth. As she had a good supply of milk, it soon drew the breast quite vigorously.

About one week after its birth, the nurse called my attention to "weak spells" which it had occasionally, accompanied by coldness of the skin, a feeble circulation, and prostration which continued for fifteen or twenty minutes, and were followed by a clammy perspiration. By the application of heat to the body, and

giving it a little brandy and water or other stimulant, it would revive.

I observed that these "spells" had a periodicity occurring every two or three days, and considering them malarial, I gave the mother quinine and valerianate of iron, which, acting therapeutically through the milk, soon caused the "spells" to cease, and the babe became well and fat. I also gave it small doses of the elixir of cinchona for several weeks.

This child must have contracted this disease whilst in utero through the placental circulation, for being born in a perfectly healthy locality it was not exposed to any external malarial influence.

When labor began the quinine was stopped, and was not resumed until the condition of the child required it, when it soon showed its antiperiodic action by completely arresting these "weak spells," for now the child is perfectly well.

Dr. R. P. Harris related a case of parallel character, which had occurred some years ago in a malarious neighborhood. The mother was under treatment before labor. The child had chills and fever when quite young, and was treated through the mother.

Dr. W. H. Baker reported for Dr. Walter F. Atlee a case of

ABDOMINAL SECTION.

Mrs. E. C., of Erie, Pa., was brought to this city by Dr. Edward Cranch. She was forty-five years of age, married, but had had no children. Her menses were regular and very abundant. She was a stout woman in excellent health. Four years ago she first noticed the tumor in the centre of the abdomen. Dr. Cranch reports that the probe enters the womb the normal distance only.

Diagnosis.—A multilocular cyst with thick walls and very glutinous liquid, or a fibroid tumor of the uterus. The sense of fluctuation was not distinct.

Operation.—February 4. After the usual preparation, cut down, found a solid tumor, opened it, took out as much as possible of the contents, and got out the envelopes; the incision was about five inches in length. The tumor grew from the fundus of the uterus. It was transfixed, tied, and dropped. The patient never rallied after the operation, and died on the 6th, of shock. There was no hemorrhage. The operation was all over in twenty-five minutes.

Dr. R. P. Harris saw the patient prior to, and assisted in the operation. The lady had an appearance of health, was quite robust, and there was nothing in the contour or expression of her face indicative of ovarian cystoma. In a conversation with her sister and family physician, he learned that the diseased growth was first noticed by this sister, who remarked upon the central prominence of the abdomen of the patient, who was at the time lying on her back on the floor engaged in playing with a little child. When the attention of the patient was directed to the fact that her abdomen presented a central elevation even when flat upon her back, she readily detected the existence of something abnormal. Dr. Harris remarked to the physician that the history of the case indicated the existence of a tumor at the fundus uteri. When the morbid growth was exposed it did not present the appearance of an ovarian cyst; neither did percussion indicate the presence of fluid prior to incising the abdomen, except by a surface wave. There was no wave transmitted from hand to hand. The surface wave was found due to some ascitic fluid. As no fluid escaped by tapping, the tumor was opened and its contents torn away in pieces, so as to reduce it sufficiently, when it was drawn through the wound, ligated at its union with the fundus uteri, and cut away. During the shelling process a considerable loss of blood took place, and the appearance of the patient was that of great prostration. The tumor had no pedicle, being sessile in its attachment to the uterus.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, February 25, 1884.

The President, S. Oakley Van der Poel, M.D., in the Chair.

Dr. E. C. Spitzka read a paper entitled

THE PATHS OF COÖRDINATION.

Progress in the localization of cerebral functions, he said in opening, had followed two different lines of research. The first was the observation and registration of phenomena following the irritation of the cerebral centres in experiments or in connection with disease. The second consisted in the anatomical study of the facts connecting certain centres with certain peripheries. The first was confessedly more or less empirical, and the two methods might be compared to two parties making an exploration of an unknown continent from different directions; the first instituting a survey of the coast and its indentations, and the second, starting from the interior and tracing out the water-courses and mountain-ranges in their relations to the coast. Between the two there would be a vast untried region, gradually diminishing in extent as the two parties approached each other. So was it in regard to the brain, in which the great intermediate region constituted a labyrinth not yet investigated; but the progress which was constantly being made in elucidating new points was gradually rendering its boundaries more and more restricted.

The case upon which the paper was based was one which Dr. Spitzka had the opportunity of studying for several years, and finally of making an autopsy in. It was one of pure unilateral ataxia without paralysis. The patient was a native of Germany, a male, and fifty-eight years of age when the trouble commenced. Dr. Spitzka saw him for the first time two months after its onset, which was characterized by a slight apoplectiform seizure, followed by numbness and impairment of co-ordination in the right arm and hand, accompanied by a ringing sensation in the part. The difficulty afterwards extended to the left lower extremity, and there was a marked clumsiness in gait, which was neither paralytic nor strictly ataxic; giving the impression of a vertiginous sensation. All the movements were of a more jerky character on the left side than on the right. Dr. Spitzka said that he made the diagnosis, at the time, of hemorrhage in the pons Varolii, and gave a qualified, unfavorable prognosis. He then gave an elaborate history of the symptoms and progress of the case, which

terminated fatally about five years after the original trouble was noted.

For two weeks before the patient died he suffered from intense cold, and death was preceded by dysphagia, delirium, and increasing coma. The main lesion discovered at the autopsy was a secondary degeneration affecting principally the stratum intermedium, which commenced about the lower third of the pons Varolii, just to the right of the median line, and extended on the right side down to the decussation of the pyramids, where it crossed to the left side. Dr. Spitzka made six hundred sections at different points in the course of the lesion, and it was found that scarcely a nerve-fibre was left in many parts. He said that there were but two cases on record resembling this. In the first, however, the anterior pyramids were also implicated, and hence its physiological importance was impaired. The second one, which was reported by Meyer, was, therefore, the only one which was strictly comparable to this. In regard to the sensation of intense cold coming on a short time before death, he said that at present he had under observation two patients suffering from paralytic dementia, in whom this was a prominent symptom. One of them was subject to successive chills, resembling those seen in severe malaria. Among the propositions that Dr. Spitzka advanced in connection with this case was one, that the stratum intermedium was probably continuous with the column of Goll, and, in conclusion, he said that he thought at least two and a half inches of the unknown labyrinth of the brain were cleared up by the light which the case threw on the paths of coördination.

DR. E. C. SEGUIN remarked that he thought Dr. Spitzka's interesting case would offer an explanation of some of the phenomena which he had observed in certain cases of his own, which he had studied during life, but in which he had not had the opportunity of making an autopsy. They were instances of brain-ataxia or hemi-ataxic tremor with parasthesia, and he had supposed them, on purely theoretical grounds, to be due to sclerosis localized in the hemispheres. Unlike Dr. Spitzka's, however, they were essentially chronic cases, and in none of them was there any history of an apoplectiform seizure. At the present time he had a case under observation in which there was ataxia of the right upper extremity, with no marked paralysis, but with some bulbar symptoms. There was slight impairment of articulation, and sometimes slight difficulty in swallowing. He thought it well to call attention to one or two difficulties in the way of adopting Dr. Spitzka's interpretation of his case. One was that the results of experiments served to show that the dorsal pyramidal or pineal decussation was sensory, and in this connection he mentioned the experiments of Brown-Séquard and others, in regard to the effect of hemi-section of the spinal cord in Guinea-pigs. So also, the symptoms produced by stab-wounds of the spinal cord, and the presence of tumors involving one-half of the cord, indicated the decussation within the cord of sensory conductors to the cerebrum. In the second place, while Dr. Spitzka had regarded ataxia as a symptom of the interruption of conduction by destruction of brain-tissue, Brown-Séquard had shown that it could be produced by simple irritation. This was very markedly the case in birds. In the human species, ataxic movements were observed when there was no secondary degeneration, and when the lesion was variously located in the cerebrum, the crura cerebri and the cerebellum. In post-paralytic chorea, as described by Dr. Weir Mitchell, a lesion was found in several cases in the internal capsule. Still, he was very much gratified that Dr. Spitzka had shown the results of this autopsy, and he could well see how it would throw some light on other cases, in connection with which there was more or less obscurity.

DR. SPITZKA said, in regard to Dr. Seguin's first objection, that he had not referred to sensation in his report of the case, but simply to coördination, and that Brown-Séquard did not allude to the muscular sense in connection with the experiments mentioned. After speaking of ataxia as a symptom of irritation, he went on to say that he did not believe the case on which he had based his paper would throw light on Dr. Seguin's cases, since he believed that they were of a different character, and belonged to the group of cases depending on a cortical or subcortical lesion. Thus there was a pure ataxia of intellectual type.

CORRESPONDENCE.

THE DWIGHT INSURANCE CASE.

To the Editor of THE MEDICAL NEWS.

SIR: I read your editorial of December 22, 1883, on the "Dwight Life Insurance Case." The case has attracted a great deal of attention, especially among the insured on this coast. Having been interested myself for many years as a life insurance examiner, I have followed the reports of the case pretty closely, and am satisfied that your views in regard to the case are entirely correct. You have stated, to my mind, the whole case in the few following sentences.

"The reason he had for taking so great an amount of insurance, may have been to secure large sums of money to his family and friends by a supreme fraud. When we reflect on the enormity of the crime, on his hopeful disposition and self-confidence, especially on the large enterprises which he had in view, it seems more rational to interpret his conduct by the light of other motives. From this point of view, the large insurance was intended to bridge over the period between the present impecuniosity, and that successful enterprise with 'millions in it,' which, as the testimony shows, he had entered upon. The disclosures of the post-mortem render it probable that he was in the incipiency of one of those forms of mental derangement characterized by expansive ideas. Pachymeningitis accompanied by a hemorrhagic extravasation is so common a condition in some forms of insanity, that we can hardly doubt its agency in this case. A large life insurance was a natural conception of a mind now about to enter on gigantic schemes of money-getting."

In confirmation of this view, allow me to give you a brief history of the following case: April 22, 1878, the agent of the Equitable Life Assurance brought to my office an applicant for examination; a gentleman whom I had known for several years, and whose family I had attended. I had known him as an active, intelligent, careful, temperate man; a lawyer by profession, but was then a broker; a man of most unexceptionable physique. I knew his means to be limited, and was surprised when I found his application called for fifty

thousand dollars. I expressed my surprise at the large amount; he replied that he had not thought of life insurance until a few hours before, when he met the agent on the street, who had suggested it to him, and that as he was about entering into some enormous schemes, the suggestion of life insurance was a good one, and he would, besides, take enough in other companies to make up two or three hundred thousand dollars. A man whom I knew to be without means, proposing to take two or three hundred thousand on his life, interested me at once. I drew him out on the grand schemes to which he referred, and found that they were wilder than the proposed enormous amount of life insurance. He was going to organize a grand mining company, which would have rivalled the schemes of John Law.

The man's manner was rather excited, his eye restless, and his pulse somewhat quick; in other respects he had an elegant physique, proportions about perfect. I informed him that his pulse was rather excited, and that I would have to postpone the examination to another time. He explained the condition of the pulse, saying he had been in the Board all day; there had been great excitement in stocks, and that he expected to make a deal that would at least net him a million or two. He was anxious that I would see him in the evening when his pulse was quiet, that he might consummate the application; as he would not apply to the other companies until he had passed this one; and that he would like to have at least a couple of hundred thousand on his life until he was successful with some of his grand schemes.

A few minutes after he had left, the agent came in and asked me if I ever had examined so perfect a risk. I replied that I had rejected him, that he was insane. The agent certainly took me for the insane man. He had known the applicant for years, had seen him almost daily on the street. I promised to reëxamine him in a week's time. About two or three weeks after the examination, there was a great excitement on the street; the applicant Willard had drawn his pistol and shot and wounded a man with whom he had had some little slight business trouble. (This was a new *rôle* for Willard.) He was immediately arrested and taken to jail. While his father-in-law was looking for bail, he met the insurance agent, who informed him that I had rejected his son-in-law Willard the week before for insanity. Acting from this clue, the father-in-law immediately summoned the Board of Insane Commissioners to examine Willard, and acquit him on the grounds of insanity. The Commissioners, after a careful examination, declared that he exhibited no traces of insanity; that he was perfectly sane and responsible for his acts. He was, however, soon bailed out; he was greatly excited and pained at what had occurred.

I was then sent for and consulted. I advised them to take him to the country to his mother's, a few miles above Stockton, where he could have perfect quiet, but for them to stop in Stockton on the way, and send for Dr. Shurtliff, who had been twenty years Superintendent of the Stockton Insane Asylum, and that I was satisfied that Dr. Shurtliff would recognize incipient cerebral disease as the real cause of his wild schemes and his attempt at shooting.

The next day they left town, stopped at Stockton and consulted Dr. Shurtliff, who found the patient much quieter, perfectly reasonable, and willing to put himself under Dr. Shurtliff's care. The doctor explained to him that this mental excitement was due to incipient brain disease, and that he had better go into the Asylum and be treated, which he did.

He was committed June 14, 1878, and remained in the Asylum until December 4, 1878, having improved some mentally, but weaker physically. Dr. Shurtliff made the following notes on the Asylum books: Paretic, but not demonstrative, except in the idea of wealth; shows paralysis in his gait, but not in speech. He died a few weeks after he left the Asylum, with cerebral disease. No post-mortem. There are strong probabilities that if I had accepted him (Willard) for fifty thousand dollars, other companies would have accepted him, and he would have had two or three hundred thousand dollars on his life within a week. And yet he had never thought of insuring his life until it had been suggested to him by accident on meeting the agent on the street a few hours before he made the application.

While the later history and death of Willard differs from Dwight, the conceptions to secure this great amount of insurance in both cases were probably the result of incipient disease. I must say, however, that I rejected Willard, not upon any objective or subjective symptoms of physical disease that I could detect, but purely upon the grounds that it would be unsafe to accept a man for life insurance who was so utterly reckless and regardless of the financial requirements necessary to carry out such enormous speculations. A sane mind must recognize that it requires some money, at least, to carry on enormous financial schemes and to pay the premiums on two or three hundred thousand dollars life insurance.

W. F. McNutt, M.D., M.R.C.S. Ed.,
Professor of the Principles and Practice of Medicine in the University of California.

THE VALUE OF LIME INHALATIONS IN DIPHTHERIA.

To the Editor of The Medical News.

Sir: In the number of your journal for March 1, 1884, there is an editorial on "The Treatment of Diphtheria." Lime is therein mentioned as a solvent of the false membrane, and it is placed next to diluted lactic acid in efficacy. The methods of application given are two in number. The first is that in which the lime is in aqueous solution, and is brought in contact with the diseased parts by means of a mop or spray producer. The second "has been effectively employed by having the patient breathe the vapor arising from slacking lime."

It is the last statement which forms the subject of my note. It is immaterial to ascertain who the originator of the method was, but from the fact that these directions are given in some text-books, are extensively practised, and are countenanced by the article referred to above, I have thought it not improper to examine into the value of using lime in this form.

A little reflection will lead one to suspect that lime vapor is only imaginary, and a simple experiment will confirm the doubt. If lime be contained in the steam which is developed during its hydration, it should be readily detected in the condensed fluid.

The vapors from slacking lime, and the distillations of the officinal lime water, as well as of milk of lime, give no response to calcium tests.

It is consequently evident from this that the value of the treatment depends on another agent. It is the vapor of hot water that has made the lime inhalations useful, and that steam has its advocates in diphtheria is mentioned in your paper.

Yours respectfully,

LOUIS KOLIPINSKI, M.D.,
Resident Physician in the Children's Hospital,
Washington, D. C.

NEWS ITEMS.

CHICAGO.

(*From our Special Correspondent.*)

THE HOSPITAL INTERNESHIP has finally become a popular thing among young medical men and hospitals in Chicago. A few years ago the County Hospital and Mercy Hospital were the only institutions where internships could be competed for. Now the Michael Reese, St. Luke, and Alexian Brothers' hospitals are added to the list. This season there has been manifested an unusual interest in the appointments in these hospitals, and so the number of candidates is large.

THE EXAMINATION OF THE INSANE.—A murder occurred about a month ago which illustrates at once the necessity of care in the examination of the insane, and the danger of insisting upon too rigid requirements in proof of insanity. Shortly before last Christmas, a man about fifty years of age, and in good physical health, but of exceedingly bad habits, was taken by his family to the Probate Court for examination. His wife and neighbors all testified that he was frequently subject to fits of the most violent and uncontrollable passion, and that he often did most uncontrollable things. He was adjudged sane, and his eccentricities attributed to intemperance. He was sent home, where he continued to live with his wife and children, and although he ceased drinking, his maniacal attacks grew more frequent and more constant. His family were too poor to send him to a private sanitarium, and felt that they were compelled to nurse him as best they could. As stated, about a month ago, after several days and nights of constant raving, he killed his wife in a most brutal manner.

INDIANAPOLIS.

(*From our Special Correspondent.*)

SMALLPOX has again made its appearance in this city, but so far has been almost entirely confined to the city. About two months ago, a case developed in the County Jail, in which about two hundred were confined at the time, the diagnosis of which was hindered by a simultaneous syphilitic eruption until the case was far advanced. Steps were immediately taken by our excellent Health Board to stamp out the plague by quarantining the jail and city station house, and vaccinating all the inmates with bovine virus. About thirty cases developed in spite of these precautions, which were all removed to the smallpox hospital as soon as the cases were diagnosed. About fifty cases in all have sprung up in the city, the greater number of the eighteen or twenty cases developed outside the jail, being recently discharged inmates. The source of the contagion has not been traced. The jail was in good condition as to cleanliness.

THE MEDICAL COLLEGE OF INDIANA.—At a recent meeting of the trustees of the "Medical College of Indiana," two new chairs were added, viz.: Diseases of the Skin, and a chair on Clinical Medicine. Dr. W. F. Hayes was elected Professor of Diseases of the Skin, and Dr. W. N. Wishard Professor of Clinical Medicine. Dr. Wishard is now Superintendent of our City Hospital. The College this year graduated forty-three.

THE INDIANA STATE MEDICAL SOCIETY MEETING has been postponed until after the meeting of the American Medical Association.

PANCREATIZED MILK.—At a recent meeting of the Marion County Medical Society of this city, Dr. F. A. Morrison, Physician to the Quilp's Orphan Asylum, read a paper on "Pancreatized Milk in the Digestive Troubles of Infants," in which he advocated the use of pancreatized mllk in raising babies by the bottle. He presented good evidence that it both cured and prevented vomiting and diarrhœa. He prepares it by adding one teaspoonful and a half of liquor pancreaticus to a pint of milk; let stand one hour; add five grains of bicarbonate of soda, and feed through the nursing-bottle. He also recommends it in acute gastritis of adults.

BERLIN.

(*From our Special Correspondent.*)

BERLIN STATISTICS IN 1883.—The statistical office of the city of Berlin (under the superintendence of Privy Councillor Boeckh) publishes the following figures which may be of general interest:

The monthly average number of inhabitants during the year 1883 was 1,207,114, with an average death-rate of 29.04 per thousand.

The month of July exhibits the highest mortality, 53.34 per thousand; the month of December the lowest, 23.54. The number of still-born children (which is *not* included in the foregoing figures) amounts to 1394, or 1.41 per thousand of the population; against 38,375, or 36.63 per thousand of births of living children.

The mortality of infants in the first year represents 37.24 per cent. of the total mortality; of those from one year until five years old, 20.49 per cent. of the same.

Among infectious diseases, only three have exerted a serious influence, viz., *diphtheria* with 7.37 per cent. (!) *measles* with 3.35 per cent., and *scarlet fever* with 2.47 per cent. of the total mortality. Death from *whooping-cough* shows 1.05 per cent. and from *typhoid fever* only 0.63 per cent. of the total number of the deceased. *Pulmonary phthisis* (with 11.47 per cent.) is not yet enlisted among infectious diseases. Death from *pneumonia* and *pleuritis* ensued in 6.79 per cent., and from *infant diarrhœa* in 8.27 per cent.

334 persons were killed by accident; 400 died by suicide; 7 were murdered, and 2 executed.

HONORARY DEGREES FROM THE UNIVERSITY OF EDINBURGH.—On the occasion of the Celebration of its Tercentenary Anniversary, the University of Edinburgh

has invited Prof. S. D. Gross, of Philadelphia; Dr. Fordyce Barker, of New York; and Dr. J. S. Billings, U. S. A., to accept the honorary degree of LL.D. Prof. Gross will be prevented from being present to receive the degree, but Drs. Barker and Billings will sail for Europe on April 2d.

BELLEVUE HOSPITAL MEDICAL COLLEGE COMMENCEMENT.—The Twenty-third Annual Commencement of this College was held in Steinway Hall, on Thursday evening, March 13th. The degree of M.D. was conferred upon one hundred and forty-nine graduates.

UNIVERSITY OF NASHVILLE, AND VANDERBILT UNIVERSITY.—The Commencement exercises of the Medical Departments of these institutions were held on February 25th. The degree of M.D. was conferred upon one hundred and twelve graduates.

UNIVERSITY OF MARYLAND; SCHOOL OF MEDICINE.—At the Seventy-seventh Annual Commencement of this School, held on March 14th, the degree of M.D. was conferred upon seventy-four graduates.

CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS, INDIANAPOLIS.—At the Annual Commencement of this College, held on February 29th, the degree of M.D. was conferred upon twelve graduates.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO.—The thirty-eighth annual commencement of this institution was held on February 26. The degree of M.D. was conferred upon sixty-two graduates.

THE NATIONAL MEDICAL COLLEGE, WASHINGTON, D. C.—The sixty-second annual commencement exercises of the National Medical College (Medical Department of Columbia University, Washington, D. C.) was held on the 20th instant, at which time fourteen gentlemen received the degree of Doctor of Medicine, and thirteen others were reported to have passed a successful examination in the primary branches.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF GEORGETOWN.—A committee of three was appointed at a recent meeting of the Faculty of the Medical Department of the University of Georgetown, D. C., to report a plan for securing a suitable building for college purposes.

POLYCLINIC IN BALTIMORE.—The Baltimore Polyclinic and Post-Graduate Medical School has been recently organized, and is located at 112 Hanover Street. The Faculty consists of Drs. Alan P. Smith, J. Edward Michael, H. Clinton McSherry, B. Bernard Browne, Thomas A. Ashby, Samuel Theobald, Robert B. Morison, Randolph Winslow, T. Barton Brune, Wm. A. Moale, John W. Chambers, Thomas S. Latimer, and Ferdinand E. Chatard.

CONFIDENTIAL COMMUNICATIONS.—MR. WILLOUGHBY N. SMITH, of the Baltimore Bar, and Lecturer on Medical Jurisprudence in the College of Physicians and Surgeons, states that the following gives correct expression to the existing rule of law on this subject in the United States:

In the absence of any statutory provision to the contrary, it is well settled that a physician or surgeon may be *compelled* to disclose any communication made to him in professional confidence.—*Stephens's Digest of Evidence*, Art. 117.

The States which have enacted statutes changing this rule of the common law are the following:

Wisconsin, New York, Michigan, Iowa, Minnesota, Missouri, Ohio, Indiana, and Nebraska.

The statute of Wisconsin provides that "no person duly authorized to practise physic or surgery, shall be *compelled* to disclose any information which he may have acquired in attending any patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon."—*Wisconsin Revised Statutes*, Sec. 4075.

The statutes adopted in New York, Michigan, Minnesota, Missouri, Ohio, Indiana, and Nebraska, provide *either*, that a "person duly authorized to practise physic or surgery" shall not be "competent," or that he shall not be "*allowed*," to make the disclosure. *But* by the statutes of Iowa, Indiana, and Minnesota, such testimony "may be received with the consent of the patient" in all cases, and in Minnesota the prohibition, in the absence of such consent, is confined to civil cases: the "regular physician or surgeon" may be *compelled* in that State, in criminal cases, to disclose communications reposed in him in confidence by a patient while in actual attendance upon the patient in the capacity of medical adviser.—*Maryland Medical Journal*, March 1, 1884.

THE CHAIR OF BOTANY IN THE UNIVERSITY OF OXFORD.—The Professorship of Botany in the University of Oxford has been recently filled by the election of DR. ISAAC BAYLEY BALFOUR, Regius Professor of Botany in the University of Glasgow. Dr. Balfour is the son of the late Prof. Balfour, of Edinburgh.

INTERNATIONAL CONGRESS OF HYGIENE.—The fifth International Congress of Hygiene will meet at the Hague, August 21 to 27, 1884. The papers to be read will consider individual and general hygiene, sanitary, police, demiography, and medical statistics.

THIRTEENTH CONGRESS OF THE GERMAN SURGICAL SOCIETY.—The Thirteenth Kongress der deutschen Gesellschaft für Chirurgie will be held on the 16th to 19th of April, in Berlin. The following papers have been announced:

1. Dr. Zesas (Zürich), The Physiological Relation between the Spleen and the Thyroid Gland—The Treatment of Paraplegia in Spondylitis.
2. Dr. Cramer (Wiesbaden), Ferment-intoxication caused by a Blood-cyst.
3. Dr. Zabludowsky (Berlin), Massage.

CHOLERA.—Consular reports from Calcutta show twenty deaths from cholera at that place during the three weeks ending January 19, 1884.

YELLOW FEVER.—There were sixteen deaths from yellow fever at Havana during February, as against ten for the same month last year. Sanitary Inspector

Burgess continues disinfecting vessels loading and unloading at suspicious wharves. Reports from Rio state that there were thirteen deaths from yellow fever for the week ending January 26, 1884.

SOME VITAL STATISTICS OF ST. PETERSBURG.—The consul at St. Petersburg, in a consular report recently made, gives the following interesting statistical data. At the examination of recruits for the Russian army, during 1882, of 1000 candidates examined, 460 were rejected as being "too narrow-chested," 50 had pulmonary tuberculosis, and 10 from "poverty of blood." On the whole, 57.5 per cent. were rejected for physical disability. It was found that over 50 per cent. of the young men of St. Petersburg between twenty and twenty-two years of age were "weak and sickly." Of the population of the city, 2000 were affected with bodily infirmities: 771 were blind; 707 deaf or dumb, or both; 188 without arms, and 282 without legs. Blindness was twice as common among women as men, but the latter show a larger proportion of cripples. Of the 771 blind, it was congenital in 134, and of the 707 deaf and dumb, it was congenital in 409,

WAR-WOUNDS.—From a calculation based on the statistics furnished by the Crimean, the Dano-Prussian, the Austro-Prussian, and the Franco-Prussian wars, it would appear that the proportion of wounds received in different parts of the body is as follows: in the head, 14.65 per cent.; in the trunk, 18.17 per cent.; in the upper extremities, 30.19; in the lower extremities, 36.91. The statistics only apply to cases which have lived long enough to receive surgical treatment, and this will account for the very low percentage of wounds of the head; and the same remark applies in hardly less degree to wounds of the trunk.—*British Medical Journal*, February 16, 1884.

MEDICAL STUDENTS AT SWISS UNIVERSITIES.—The medical students of the Swiss universities are thus distributed, according to the *Lancet* of February 9, 1884: Basle, 108; Berne, 127 males and 28 females; Zurich, 184 males and 33 females; Geneva, 84 males and 7 females. Only five of the women are Swiss, all the others being Russian.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending March 8, 1884, indicate that influenza and dysentery have increased, and that rheumatism and consumption have decreased in area of prevalence.

Including reports by regular observers and others, diphtheria was reported present during the week ending March 8th, and since, at twelve places, scarlet fever at twenty-four places, and measles at seven places. One case of smallpox was reported in Bath Township, March 7th.

OBITUARY RECORD.—Died in Louisville, on March 12th, of neuralgia of the heart, LUNSFORD PITTS YANDELL, M.D. For several years he has been well known as the able editor of the *Louisville Medical News*.

A little more than six years ago his illustrious father, whose name he bore, passed away at the ripe age of seventy-three, and now the son, at least twenty years his junior, has gone over to the majority. Alas that a life thus incomplete, unfinished, should meet with such abrupt end! The father died in the evening after a day of marked usefulness and great honor, but the son, when noon was but little passed, in the meridian of his power, filling an important place as teacher, editor, and practitioner. To his widow and to his children—too young to understand the greatness of their loss—as well as to his brother, Dr. David W. Yandell, thus left in sad loneliness, the hearty sympathies of the profession are freely given.

——In Philadelphia, on March 17th, after a long illness, CASPAR MORRIS, M.D., aged 79 years. Dr. Morris was born in Philadelphia, in 1805. He received his degree in Medicine from the University of Pennsylvania in 1826. After a term of residency in the Pennsylvania Hospital, he went to India as surgeon of a ship. On his return he commenced practice in Philadelphia. He was for some time Lecturer on Diseases of Children in the Philadelphia Hospital, and on the Practice of Medicine in the Philadelphia Medical Institute; and he was the author of a volume of lectures on *Scarlet Fever*.

Dr. Morris was greatly esteemed for his gentleness and purity of character, as well as for his integrity and high sense of honor, and he was beloved by all who had the good fortune to know him as friend, physician, or citizen.

CORRIGENDUM.

DR. F. LANGE, of New York, requests us to state that some six months ago he resigned the position of Visiting Surgeon to Bellevue Hospital, and that, therefore, this appointment, which was appended to his name on page 255 in our issue of last week, does not now belong to him.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 11 TO MARCH 17, 1884.

BILLINGS, JOHN S., *Major and Surgeon.*—Granted leave of absence for one month with permission to go beyond the sea, to take effect April 1, 1884.—*Par. 6, S. O. 61, A. G. O.*, March 13, 1884.

BACHE, DALLAS, *Major and Surgeon.*—Leave of absence still further extended seven days.—*Par 1, S. O. 50, Headquarters Department of the East*, March 14, 1884.

HEIZMANN, CHARLES L., *Captain and Assistant Surgeon.*—Leave of absence extended three months.—*Par. 9, S. O. 57, A. G. O.*, March 8, 1884.

BLACK, CHARLES S., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Concho, Texas.—*Par, 6, S. O. 30, Headquarters Department of Texas*, March 10. 1884.

KNEEDLER, WILLIAM L., *First Lieutenant and Assistant Surgeon.*—Assigned to temporary duty at Fort A. Lincoln, D. T.—*Par. 3, S. O. 26, Headquarters Department of Dakota*, March 8, 1884.

WALES, PHILIP G.—Appointed to be Assistant Surgeon with the rank of First Lieutenant, to date from February 7, 1884, vice Brewster, resigned.—*Mem. A. G. O.*, March 10, 1884.

THE MEDICAL NEWS will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

ON THE TREATMENT OF TYPHOID FEVER.

A Clinical Lecture.

BY PROF. DUJARDIN-BEAUMETZ,
OF PARIS.

(Continued from page 324.)

GENTLEMEN: I pass now to the proper medical treatment of the disease. I shall commence by reviewing the different kinds of treatment which have been in vogue; then we shall examine the approved medicinal measures, and the indications for their employment during the regular course of the fever and during the complications.

The different kinds of treatment of typhoid fever may be arranged in three principal groups. In the first, it is the fever alone which demands attention; in the second, it is the typhoid poison or miasm which is to be combated; in the third, it is empiricism which has directed the treatment. Hence we will examine successively the antipyretic treatment, the parasiticide treatment, and the empirical treatment.

We find in the antipyretic medication the same divisions as in the previous chapter, viz., we shall have to examine successively refrigerants and antipyretics. Refrigerant medication has found in the treatment of typhoid fever one of its principal applications, and we shall have to study here, cold baths, tepid baths, refrigerant apparatus, cold affusions, and lavements.

There is no question in therapeutics which has of late years provoked more vehement discussion than that of the application of cold baths to the treatment of typhoid fever; and this method to which Brand has justly given his name, for he it is who has furnished it with a rigorous and mathematical formulation, has been attacked and defended by resolute adversaries and determined partisans. I myself have taken part in this debate, and I am going to set forth as impartially as possible the advantages and disadvantages of this method.

Brand has thus formulated the treatment by cold baths. "You must administer baths of 64° to 68° F. of fifteen minutes' duration, from the fifth day of the fever; these must be repeated day and night every three hours, as long as the temperature of the rectum exceeds 102° F." In applying rigorously this method, so simple in appearance, Brand considered himself warranted in affirming, *that every case of typhoid fever treated regularly from the beginning by cold water, will be exempt from complications, and will get well.*

I shall not here enter into the details of Brand's method, details which pertain to the manner in which the patient should take the bath; and I refer you in this regard to the minute directions which Dr. Chapuis has given in his thesis (Paris, 1883), and which are founded on the technics in usage in the hospitals of Lyons. Lyons is, in fact, the only city in France where Brand's method is used in all its rigor, under the persevering efforts of Dr. Glenard, who, during his captivity at Stettin, had an opportunity to witness the results which Brand was obtaining. Dr. Glenard must congratulate himself on the success which has attended his persevering efforts, for we see almost complete unanimity in the hospitals of Lyons in reference to this refrigerant medication.

It is upon statistics that the partisans of this method base their arguments almost exclusively. Jaccoud, from a review of more than eighty thousand cases, arrived at an estimate that the average mortality in typhoid fever was 19.23 per cent. On the other hand, taking as a point of comparison the military hospitals, and in reckoning under a common title the continued fevers and typhoid fever, a mortality of fourteen per cent. is obtained. The application of Brand's method has caused a considerable fall in the percentage of deaths, since, out of thirty thousand cases treated by cold baths, there was a mortality of only nine per cent., and in the case of the military hospitals, of only seven per cent., or even less; and if we may rely upon the figures furnished by Abel, Physician in Chief of the Second Corps of the Prussian Army, in Pomerania, the mortality was reduced to nothing.

What is the real value of such captivating figures as these? You know already my opinion concerning statistics as applied to therapeutical results—I expressed them very clearly while on the treatment of pneumonia—I have not changed my mind, and I persist in considering statistics as an unreliable criterion of the results of our treatment, because, in order that this method may give positive results, it is essential that the individual cases which are collected and compared together shall be proper subjects for comparison, a thing which does not happen in pathology. Take, for example, typhoid fever. Do you believe that one typhoid patient is exactly like another typhoid patient? The age of the patient, the state of his vital forces, the relative severity of the epidemic, the period of the year, the nature of the locality even, have a great influence on this pathological aggregate, and modify its march and its fatality. It is here especially that we see the influence of what I have called the morbid genius of epidemics, where one sees epidemics relatively benign, succeed epidemics that were malignant; and according as you apply the same method of treatment to the first or to the second, you will have multiplied successes or almost constant failures.

The arguments, Gentlemen, which I adduce against statistics, I can in turn obtain from statistics themselves, and to the figures so convincing of Brand, of Glenard, of Strube, of Abel, etc., I need only oppose those of Schmidt of Erlangen, of Goltdammer of Berlin, of Boudet of Lyons, which show us that by rigorously employing the cold-bath medication the rate of mortality is considerably increased, approaching, as it does, a mean of nineteen per cent., and even exceeding this sometimes. I might even compare the other methods

of treatment with that of Brand, and show you also by figures that the refrigerant method has nothing to boast of.

I know well the objection which the partisans of the cold-bath cure make to these last statistics. They tell us that in these cases Brand's system of treatment was not carried out with mathematical precision, and according to his rules, and what is of more importance, it was not employed from the very commencement of the disease. My reply to this objection is more formal, and I assert that in the majority of cases, and outside of military practice—for which I make some reservation—the method of Brand is impracticable, both in our hospitals and in private practice. Not that I believe that we cannot in our hospitals and in our ordinary practice succeed in giving, despite the difficulties which attend them, cold baths day and night to our patients, but because it is necessary, according to Brand, to give these baths before the fifth day of the disease. Never do patients enter our hospitals at this period, and when they do enter, as we cannot be sure of our diagnosis till after the seventh day, it is not till this date that the cold-bath treatment can be commenced.

To this objection, Brand's partisans have replied categorically, and Bard has given the reply in this concise form: "In order that the method of Brand may have full efficacy, all fever patients should, without distinction, be subjected to the bath; *the bath will know its own.*" I do not know if the bath will "know its own" or not; but what I do know is, that we cannot, without danger, subject all our fever patients to a rigorous and severe method, and when we are ignorant of the cause even of the febrile process. Do you believe that the cold bath may not determine profound congestions? Do you believe that you can thus, without danger, force the circulating blood from the cutaneous surface to the central parts? My colleague and friend, Dumontpallier, has well argued that the slow and progressive refrigeration does not provoke visceral congestion; but to the clinical and experimental facts to which he appeals, I have opposed experiments and observations absolutely contrary to these views.[1] Brand's method, whatever one may say, is not free from danger, and not a few of the complications which supervene on the part of the lungs or intestines, in patients submitted to this treatment, may be attributed to it. As for the pulmonary liabilities, there is no doubt that as a result of the cold-bath medication congestions and inflammations of the lungs have arisen; and during the discussion which took place in 1876 and 1877, in the Society of the Hospitals, this fact greatly impressed the majority of those who took part in these debates.

I must say as much as regards intestinal hemorrhage; I believe that in certain cases the cold baths may favor these hemorrhages in patients who are predisposed. These complications, moreover, on the part of the lungs and intestines, are quite explicable from the very action of the cold baths which are employed.

Where do you suppose the blood goes to which circulates at the periphery when it is driven inwardly by the vaso-motor constrictive action of the cold bath and ice-water lotions? The blood cannot find refuge except in the internal organs, and this reflux cannot but favor congestion of the abdominal viscera. Soulier has made many experiments on animals to show that the vaso-motor constriction is produced almost at the same time at the surface and in the central organs; but I believe that these experiments, however careful they may have been, place the animal in quite different circumstances from those of our typhoid patients.

To sum up, I consider the exclusive method of Brand, and the rigorous and mathematical rules which he has formulated, as deserving to be banished from the treatment of typhoid fever, and for this reason especially—because it requires, in order to derive from it all the results which it promises, to be applied before the diagnosis can be certain; for, employed later, this system only gives—according to the acknowledgment of its most zealous partisans—results comparable with those of other therapeutic methods, and with greater danger to the patients. You will see, in fact, that we have for the treatment of certain manifestations of abdominal typhus, hydro-therapeutic means much less dangerous and quite as powerful—not, perhaps, from the point of view of hyperyrexia, but from that of the other symptoms of typhoid fever; for, in my opinion, the advocates of the refrigerant medication have committed an error in vociferating, "The hyperpyrexia! behold the enemy!" The hyperpyrexia, as Peter has well said, does not constitute all the danger of the disease, of which it is only one of the manifestations.

Tepid baths are, in my judgment, much more applicable to ordinary cases of this disease, and I pointed out several years ago the advantages which might be derived from these baths, which, as my hospital experience has shown, have an antipyretic action much less marked than that of cold baths, but are absolutely safe. They allay the excitement of the nervous system, diminish the sensation of burning heat, and enable us to maintain perfect cleanliness in our patients.

There are two ways of administering tepid baths. Some, as Ziemssen, Schutzenberger, and Laure, of Lyons, employ baths of decreasing temperature, and from 95° F. they lower the temperature of the water, in the course of ten minutes, to 77° F. Others, and I am of their number, keep the warm bath at a constant temperature of five degrees below that of the patient, to wit, varying from 93° F. to 98° F. These baths should be of much longer duration than the cold baths, and without going as far as Reiss, who keeps the patient in them almost all the time, I am of the opinion, relying especially on the experiments of Thery, that it is sufficient to prolong them from twenty to thirty minutes. These baths are repeated once or twice a day, the attendant having care to sustain the forces of the patient by giving him, during the bath, wine and meat broths. I have always seen, under the influence of these tepid baths, typhoid patients with hyperpyrexia and delirium manifest a notable amelioration of the symptoms, become calm, and obtain quiet sleep.

I shall say little about the employment of refrigerant apparatus, not because I doubt their value—on the contrary, they are the only means which enable us to apply, systematically and rigorously, the refrigerant method—but because I have had no personal experience with regard to them. They are, in fact, quite

[1] Dumontpallier, on the Refrigerant Method. Gaz. des Hôp., March 13, 1883. Dujardin-Beaumetz on Refrigerant Medication, Un. Méd., 1883.

complicated and costly, and this is the reason why no one but their inventor, my colleague, Dumontpallier, has applied them in practice. If we refer to the conclusions which he has recently formulated, these apparatus have given him good results. We find means much more easy of application in cold affusions, lotions, and the wet pack, which can be used by anybody.

Affusions of cold water, or rather of sea-water, which was Currie's treatment of fevers, are no longer in use, and the cold lotions of which I have already spoken are far preferable. These lotions of cold water are decidedly antithermic in their action, as no one who has watched their effect can have failed to observe; the temperature falls appreciably under their use, especially if they are repeated several times a day. This heat-reducing power is, I well know, limited, and in certain grave cases of ileo-typhus these lotions do not suffice to bring down the temperature, and we must have recourse to more active means. I believe the refrigerant action of these lotions to be a secondary effect, the principal and dominant action being that which they exert on the vaso-motor functions of the cutaneous capillary network, functions so profoundly disturbed in typhoid fever, and which tend to become restored under the influence of these cold lavations or spongings.

This vaso-motor and revulsive action is much more energetic when the wet pack is used. The method is very simple; the patient, in a state of nudity, is wrapped from head to foot in a sheet or blanket wrung out of ice-cold water. It is well, as a preliminary step, to have a rubber blanket spread upon a mattress; over this you place the wet sheet, in which you wrap your patient. Liebermeister advises that this envelopment should be continued for ten minutes; for my part, I prefer a shorter duration of a minute or so, after which the patient is taken from the wet sheet and removed to his bed. If I prefer wet wrappings of short duration, to the practice of Liebermeister, it is because I do not wish to obtain refrigeration from these envelopments, but only a *regulative modification* of the nervous system, and this effect will be the more marked, the shorter the duration of the cold application. This is, Gentlemen, one of our most powerful modes of treatment in cases of typhoid fever of ataxic and adynamic character, and you will derive great benefit from it. Foltz has recently added cold lavements to the refrigerant medication. These lavements of water at 50° F., lower the temperature of patients—in a feeble manner it is true—but still appreciably, and this is a fact worthy of being remembered. So whenever you have occasion to give enemata to typhoid patients, see to it that the water which you use is cold.

Having finished refrigerants, I pass now, in accordance with the order which I adopted in the previous lecture, to bloodletting.

Very much in use in the treatment of fevers at the commencement of this century, and before we had precise notions respecting the nature of typhoid fever, bloodletting was still practised at a later date in this disease by Louis and Chomel, and especially by Bouillaud, who thought to *jugulate* the disease by applying to it the formula of "bleeding upon bleeding" (*coup sur coup*). To-day the practice of bloodletting, local or general, is completely abandoned; and, nevertheless, whenever nature herself proceeds to the letting of blood, and when these losses do not exceed certain limits, we see the temperature fall, and symptoms of the greatest gravity abate; so that, in a great many cases, intestinal hemorrhages are an element of prognosis rather favorable than otherwise. The two clinical charts which I here show you, indicate well the antithermal action of these hemorrhages. It is true that you sometimes purchase this amelioration by a long and painful convalescence; however this may be, we note the fact without venturing to authorize the interference of the physician in order to produce artificially, in typhoid patients, loss of blood.

I now come to the study of medicaments which act on the fever by the intermediation of the nervous system, and we shall examine successively the treatment of typhoid fever by digitalis, aconite, veratrum viride, and sulphate of quinine.

It is Hirtz who, in our country, has defended with the most ardor the treatment of this fever with digitalis, a practice already adopted since 1862 by Wunderlich. Digitalis is given in the form of infusion, and fifteen to thirty grains of the powdered leaves are steeped in a gill of water, all of which is administered daily in divided doses. These doses, continued for three days, cause a notable diminution of the pulse and temperature, but despite this powerful antithermic effect, which is not denied by any observer, this kind of treatment is not much in favor. One fears, with reason, the action of digitalis on the heart, which is so often affected, as we have seen, with symptomatic myositis, as well as the emeto-cathartic effects which digitalis determines when given in such large doses.

I shall not take up your time with the treatment by aconite recommended by Lavasseur and Deshayes, of Rouen, nor with that of veratrum viride employed by Hirtz, Vogt, and Liebermeister, their trials not having been since repeated; at the same time remarking, *à propos* of the first of these medicines, that if you wish to experiment with aconite you should use the tincture of the root and not that of the leaves, the latter having no medicinal virtue, and I pass now to the study of a kind of treatment which has numerous partisans at home as well as abroad. I refer to the medication of typhoid fever by quinine.

Broqua, of Mirande, in 1840, communicated to the Academy of Medicine the good results which he had obtained in the treatment of typhoid fever with large doses of sulphate of quinine, and we have seen successively Chappotain, of St. Laurent, Pereira, Boucher, of Ville Jossy, Blache, Briquet, and Monneret boast of the effects of this medication. Monneret went the furthest in this direction, for endeavoring to substitute for poisoning by the typhogenous miasm the toxic effect of quinine, he was in the habit of administering as much as seventy-five grains a day of this medicine. Such bold experiments were sometimes followed by bad results; therefore this medication was abandoned, at least in our country. Vogt, in 1858, and Wachsmuth, in 1863, and, lastly, Liebermeister, in 1867, repeated these first trials, but this time they applied to the study of the effects of the medicament the use of the thermometer, and gave precise indications of the administration of the medicine. This treatment was rapidly adopted in foreign lands and in France, and we see Lindwurm, of Munich, Œffner, Larsen, of Copenhagen,

Pawer, Kaulich, Jaccoud, Germain Sée, Herard, Barthez, and others, put in practice this medication.

It is the sulphate of quinine that is most often employed; yet in Germany use is made of the hydrochlorate, and in France Jaccoud prescribes the bibromhydrate of quinine. These salts are administered in solution, or oftener in capsules; the pill form should be discarded, for it not seldom happens that on account of the state of the digestive tube, these pills pass through the intestinal canal unaltered. But the capital point, and it is this on which Liebermeister has insisted, is to give large doses; for example, you should make your patient take eight grains every fifteen minutes till half a drachm has been reached. Liebermeister often exceeds this quantity, and continues giving the small doses every quarter of an hour till from forty to sixty grains are administered, but in this country we generally stop at half a drachm.

The period of administration of these massive doses has also a great importance. Liebermeister counsels to give the quinine between five and seven o'clock in the evening; Germain Sée prefers the morning; Jaccoud, with good reason, says that you should give it in the morning or evening, according to the effect which you desire to obtain. Do you wish, for instance, to procure a lowering of the evening temperature? give your quinine in the morning; Do you wish to obtain a matinal fall? give it in the evening. Leibermeister and Kaulich give one large full dose on one day only, and do not repeat the dose unless the temperature takes on again an ascending march. Jaccoud gives his salt of quinine in decreasing doses for three days. Sée administers it without interruption. I believe that the method by interruption has great advantages over the continuous employ of the medicament, and you ought to be guided in this regard by the thermometric curve.

Employed after this fashion, sulphate of quinine produces in typhoid patients a very pronounced depression of the pulse and temperature, which lasts often for two days, and when the thermal curve rises it does not attain as high a point as before the exhibition of the quinine. But this antipyretic action, obtained with such large doses of quinine, has certain disadvantages. In giving to the patient thirty, and often forty or more grains of quinine, you are likely to overstep the therapeutic effect, and obtain the toxic action on the brain and on the heart. Germain Sée and Rochefontaine affirm that this cardiac action is of a tonic kind, but Laborde, with much reason, maintains that it is dangerous in hearts with degenerated muscular fibre, and you know that the latter is a very common complication in the infectious diseases. Moreover (and this is an argument which I adduced in the last discussion at the Academy), the typhoid patient is a bad subject for treatment, not only because absorption of medicines is difficult in consequence of the unhealthy state of the digestive tube and the lymphatic vessels, which originate there, but also because the functions of the kidney and the liver are notably compromised. In a former course of lectures I showed you the capital importance of the liver and of the kidney from the point of view of the action of medicines, and from all these considerations you see how easy it is, when drugging your typhoid patients, to exceed the therapeutic and obtain the toxic action of your remedial agents.

You ought always, Gentlemen, to have these facts in mind when prescribing active medicines in large doses to your patients in this fever. And while recognizing the benefits of quinine medication, I believe that it is best to be very prudent in the administration of this alkaloid, and never to exceed the dose of thirty grains a day, and always to have care not to give this medicament continuously. Therefore, I much prefer, as an antipyretic, salicylic acid to quinine, because one obtains antithermic effects quite as powerful with the former, and in doses which entail less danger.

It was Riess who first, in 1875, applied salicylic acid to the treatment of typhoid fever; and since this first trial, Schroeder, Nathan, Fischer, Ewald, Goldtammer, Bælz, in foreign lands, and in France, Garcin, Noel Gueneau de Mussy, Jaccoud, Oulmont, Hallopeau, Caussidon, and Rabeau, and, especially, Prof. Vulpian, have shown us the advantages which may be derived from salicylic acid in this disease. Salicylate of soda, salicylate of bismuth, and salicylic acid have severally been employed. Salicylate of soda is preferred by the greater part of German physicians, as producing less irritation of the alimentary canal than salicylic acid, and as being quite as good an antipyretic. I do not hold this opinion, and believe with Prof. Vulpian, supported as is this belief by numerous cases occurring in my hospital practice, that salicylic acid possesses—in equal dose—an antifebrile action far superior to that of salicylate of soda; and I am as much a partisan of salicylic acid in the treatment of this fever as I am of the salicylates when it is a question of rheumatic fever. Salicylate of bismuth, which I was the first, I believe, to employ in therapeutics (not, indeed, in typhoid fever, but to combat the fetid diarrhœa of infancy), has been utilized by Vulpian in the treatment of dothinenteritis. Guided by the idea—very just, indeed—that typhogenous virus develops especially in the last portion of the small intestine, Vulpian thought of this medicament, which seemed to him likely to reach without any alteration the diseased places in the intestine, and there combat, *in situ*, the development of the infectious organisms. But the results have not met his expectations; salicylate of bismuth has, indeed, lowered the temperature, but it has had no influence on the march of the disease. So, despite the more satisfying results which Desplats has obtained, this medication has not found much favor.

Salicylic acid should be administered in capsules, and in a dose not exceeding sixty grains, for more than this determines, especially in females, cerebral excitation, buzzings in the ears, and gastro-intestinal irritation. I, moreover, am always careful to give at the same time a little milk to mitigate the symptoms of the latter, and when I come to speak more particularly of the details of management of this fever, I shall tell you the rules which I follow in giving salicylic acid. In doses of from half a drachm to a drachm it lowers the temperature two or three degrees without much influencing the pulse. By not exceeding this quantity of the medicament, I have never observed any cardiac or nervous symptoms to follow. It is not so with the next antipyretic of which I shall speak, viz., carbolic acid.

Desplats, of Lille, was the first to found the *phenic medication* of typhoid fever; the trials made previously by Pecholier, Tempesto, and Skinner were not

successful, by reason of the small doses given. Desplats gives phenic acid in lavements containing twenty to thirty grains, and gives three or four of these a day; these lavements should be retained so that the medicament may be absorbed. Phenic acid has a considerable antipyretic action, and for my part I have seen doses of less than half a drachm administered in lavements, produce a fall in the fever of nearly five degrees. Such an antipyretic action is not, however, produced without danger; it is, in fact, accompanied with profuse sweats, pallor of the integument, and often an alarming state of collapse.

Last year (in 1882), I often had recourse to carbolic lavements, and frequently observed pulmonary congestions in patients thus treated; in calling to mind the toxic effects noted in animals poisoned by phenic acid, where these pulmonary congestions are the rule, I attributed to my medication a certain part in the production of these thoracic complications, and discontinued the employ of these phenic lavements. Since then, at the Medical Society of the Hospitals, at the time of the discussion which followed the report of Ferrand on the method of Desplats, several of our colleagues, and in particular Siredey and Dreyfus Brissac, mentioned similar facts; therefore, Gentlemen, while recognizing the powerful antipyretic action of phenic acid, this medication must be considered as dangerous, and when you have recourse to it you cannot exercise too great care and watchfulness. For my part, I think it should be abandoned altogether.

Resorcin has been little used in typhoid fever. You will see, when I come to speak of intermittent fever, that it has been used to advantage in this fever, but although I have made many attempts to introduce this substance into the therapeutics of our country, I have not obtained any very positive effects from it in ileo-typhus. As for kairine, I am not aware of any definite results which have been obtained from it in this disease.

(To be concluded.)

THE TREATMENT OF FRACTURES OF THE PATELLA BY THE PLASTER-OF-PARIS SPLINT.[1]

By JAMES L. LITTLE, M.D.,

PROFESSOR OF CLINICAL AND OPERATIVE SURGERY IN THE POST-GRADUATE MEDICAL SCHOOL, NEW YORK; PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.

In presenting this subject to the Society this evening, I wish to describe the method of treating simple transverse fractures of the patella with plaster of Paris, which I have used since 1863, and which has never before been described. I am also anxious that it shall serve to draw out a full discussion upon the treatment of this important injury.

The plaster-of-Paris *bandage* has been more frequently used, and the results have not been sufficiently satisfactory to prevent Hamilton from condemning it in these words: "Plaster of Paris is, of all the forms of immovable dressings, the worst, because it is the heaviest; but of them all it must be said that they are necessarily cumbrous as a form of portative apparatus; they are, to some extent, dangerous, especially in the hands of inexperienced surgeons; they are inefficient as a means of approximating the fragments; they actually serve but one single purpose, namely, to keep the limbs straight; and this they do too effectually in many cases, causing an unnecessary degree of passive ankylosis. The limb can be maintained in a straight position by a much simpler and lighter dressing than a plaster-of-Paris splint, and by means which permit it to be daily examined and the condition of the fragments noted and corrected, and which will allow slight passive motion occasionally to the knee-joint, a practice which has been found in my experience perfectly safe, and useful in some measure, as far as the ankylosis is concerned. In short, to apply the plaster of Paris, and permit the patient to go about on crutches, as is generally acknowledged by its advocates, is to abandon practically every acknowledged indication of treatment, except straighening the limb and securing immobility at the knee-joint."[1]

This criticism, from so high an authority, has evidently been drawn out by his observation on the treatment of the fracture in question by the plaster-of-Paris *bandage*. It will, perhaps, be best for me to state at the outset, in order to avoid a misunderstanding, that I always make a distinction between the plaster-of-Paris *bandage* and the plaster-of-Paris *splint*; two entirely different methods of using this material. The method which I propose to describe is by the use of the plaster-of-Paris splint, which was first introduced by me in 1861, and first applied to a fracture of the patella, in 1863, in a patient of the late Dr. Tucker, of this city, and which I have used in all the cases that have come under my care in St. Luke's and St. Vincent's Hospitals, as well as in my private practice.

Immediately after the receipt of the injury, I elevate the limb slightly, and place it on a pillow, or a single inclined plane, and wait until the swelling and inflammatory action which follow have subsided. The limb is placed in this position simply for the comfort of the patient, and not for the purpose of relaxing the quadriceps extensor muscle, and thus preventing the separation of the fragments, which was formerly considered necessary. Although I have often attempted, I have never been able, to demonstrate that it made any appreciable difference in regard to the separation of the fragments whether the limb was in a straight position or the thigh flexed on the pelvis.

Sometimes, when the effusion into the synovial cavity is great, I apply pressure as soon as the patient is able to bear it, by means of a bandage. When the swelling has subsided, which takes from five days to a week, the following dressing is applied: A posterior splint is made of two thicknesses of bleached Canton flannel, strengthened in the middle, under the knee, by two extra layers; this

[1] Read before the New York Surgical Society, March 11, 1884.

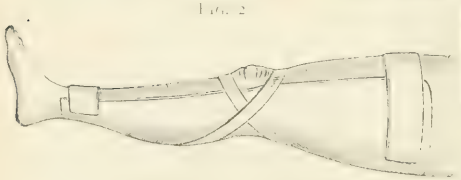
[1] A Practical Treatise on Fractures and Dislocations, by Frank H. Hamilton, 1880, p. 522.

is made long enough to reach from a little above the ankle to above the middle of the thigh, and wide enough to cover two-thirds of the circumference of the limb above and below the joint, but at the joint it should only just cover the condyles of the femur. Two pieces of Canton flannel, of from two and a half to three inches in width, double thickness, one long enough nearly to encircle the limb at the ankle, the other to encircle it at the upper third of the thigh, are prepared at the same time. The pieces designed for the posterior splint are then thoroughly saturated in a mixture of plaster of Paris and water, taking care that the mixture is not too thick,[1] and then smoothed out upon a board with the hand, and applied smoothly to the limb. Then the two bands are prepared in the same way and applied around the upper and lower extremities to hold it in position. A dry roller bandage is then firmly applied over all, and the plaster allowed to set.

As soon as this is accomplished the bandage is removed, and we have a firm posterior splint, secured above and below by transverse bands.[2] Two other strips, of a double thickness of Canton flannel an inch wide, and long enough to overlap on the posterior surface of the splint, are saturated in a fresh mixture of plaster of Paris and then tightly applied above and below the patella, while the fragments are held in position by an assistant, in the same manner as adhesive straps are used for coaptation in this fracture. A dry roller bandage is then rapidly applied with the figure-of-eight turns over the strips. The surgeon then, with thumb and finger of each hand over these coaptation bands, forces the fragments into close approximation,[3] and holds them

FIG. 1.

FIG. 2.



there until the plaster has set (Fig. 1). The bandage is then removed and a fresh one applied over the whole length of the limb.[1] The dressing is then complete. Fig. 2 shows the splint with the bandage removed.

It is a good plan for the surgeon, before applying the coaptation bands, to see that the fragments can be easily approximated In a number of cases I have found some difficulty in keeping the fragments in the same plane, or in preventing them from tilting, there being a tendency for one to rise above the other. This can be overcome by making pressure with the fingers over the line of fracture while waiting for the bands to harden.

This dressing differs essentially from all others, in that the fragments are adjusted by the hands of the surgeon, and the "setting" of the plaster keeps them in the exact position in which they were held.

With this dressing the patient is not compelled to keep his bed, but may sit up or go about on crutches with but little inconvenience.

This apparatus, like all plaster-of-Paris splints, should be applied directly against the skin, care being taken, however, to remove the hair, or else smear the limb with vaseline or oil.

The condition of the fragments can now be examined at any time by simply removing the bandage, and, in case any separation has taken place in consequence of the shrinkage of the limb, it can be corrected by removing the coaptation bands and applying new ones. Care should be taken, if this becomes necessary, which is seldom the case, to moisten the posterior splint in order to insure the adherence of the new pieces.

This overcomes one of the objections urged by Dr. Hamilton—the inefficiency of this dressing as a means of approximating the fragments. Another objection which he makes, in regard to the weight of the splint, is not at all applicable, as patients have never complained of this, and I doubt very much if it weighs any more than the apparatus he recommends.

Pressure sores have never been produced in my experience, nor have the patients ever complained of any pain caused by undue tightness of the dressing. In fact, constriction of the limb by the splint, bands, or bandages, so as to interfere with the circulation, cannot occur, even in inexperienced hands. In this respect it is safer than the plaster-of-Paris bandage which Hamilton so justly condemns.

In order to prevent a rough edge at the upper and lower extremities of the splint, it is advisable to fold them over about half an inch, thus bringing a perfectly smooth edge in contact with the soft parts.

This dressing should be left on for from six to eight weeks. The majority of patients rarely have any appreciable separation of the fragments at the end of the treatment, but as the union is generally ligamentous, a certain amount of separation will take place in time, as in all cases in which there is not bony union.

A case that I treated ten years ago, by this method, came under my notice again a few weeks

[1] Superfine or dental plaster should be obtained. The mixture should be about the consistency of cream.

[2] Sometimes I apply a third band between the knee and the lower one.

[3] The lower coaptation band holds the lower fragment fixed, and at the same time enables the surgeon to make counter-pressure while he forces the upper fragment in position.

[1] I have sometimes applied a plaster-of-Paris bandage over the splint. This makes a very strong dressing, but it prevents the inspection of the fragments during the course of the treatment, for this reason I prefer the dry muslin bandage.

since; the fragments, which after the treatment were almost in direct contact, I found had separated only a little more than half an inch.

Two cases treated by this apparatus, at St. Vincent's Hospital, resulted in bony union. The first case, a man, about forty years of age, was treated for a transverse fracture of the right patella.

After the apparatus was removed no separation or motion of the fragments could be detected. He remained in the hospital about three months. Six weeks after he left, he was brought back with a severe injury of the head, from which he died. The patella was removed, and was found to have united by bone (Fig. 3). The specimen which I show the

FIG. 3.

Society has been carefully examined, by section, by Prof. W. H. Welch, of Bellevue Hospital Medical College, and he states that it is true bony union (Fig. 4). The line of fracture is slightly oblique,

FIG. 4.

from above downwards and outwards. The lower fragment is somewhat tilted, and overlaps the upper a little; it is also displaced outwards one-quarter of an inch.

This interesting specimen belongs to the late Prof. James R. Wood's collection in the Bellevue Hospital Museum.

In the second case, treated by Prof. F. S. Dennis, although the patient was eighty-six years of age, no separation or movement of the fragments could be detected when he left the hospital.

In comparing this method with the one of wiring the patella in simple fractures, under antiseptic precautions, which has lately come into vogue, I am inclined to give the preference to the one just described, or to any other form of dressing which results in close ligamentous union. The patient is not submitted to a surgical operation which may endanger his life or the usefulness of his knee-joint, for, with the utmost care in antiseptic measures, there is still the possibility of serious complications. I think all surgeons will agree, that a moderate amount of separation of the fragments by a ligamentous band, does not in any way interfere with the usefulness of the limb. Hamilton says "that if the ligamentous band is not more than an inch in length, the use of the limb is not impaired." In a case which I presented at one of the meetings of the Society about two years ago, a patient, aged twenty-two, broke his patella transversely below its middle. He was treated by me in St. Luke's Hospital, and was discharged with a ligamentous union of less than half an inch. Six months after, he slipped in walking and fractured the same patella about half an inch above the first fracture; this also united by ligament. In this case the ligament proved itself stronger than the original bone.

If, then, ligamentous union of a moderate length does not impair the usefulness of the limb and is as strong, if not stronger, than the original bone, why should we submit the patient to any serious danger, in order to obtain bony union, which at the best is of questionable utility?

While bony union, obtained by wiring, may be the goal for which the idealist strives, I question whether it can ever be conscientiously adopted by conservative surgeons.

THE TREATMENT OF TYPHOID FEVER.[1]

BY GEORGE L. PEABODY, M.D.,

VISITING PHYSICIAN TO BELLEVUE HOSPITAL; PATHOLOGIST TO THE NEW YORK HOSPITAL, ETC.

IN rising to open the discussion of the treatment of typhoid fever one cannot help being impressed with the fact that he is approaching a subject the importance of which is not surpassed in the entire range of therapeutics. Very few diseases require such unremitting watchfulness or as careful and discriminating judgment, on the part of the practitioner, as the subject of our discussion this evening, and in very few diseases are we able to see the direct effect of therapeutics with more precision and certainty.

Inasmuch as I am to be followed this evening by men whose researches and experience, in relation to this disease, have already made them known throughout the medical world, men whose remarks will give dignity and weight to the proceedings of this Society long after the cause of its existence shall have been forgotten, I will occupy a small portion of your time only, and will direct my remarks chiefly to some of the salient points in the treatment of the more important symptoms of typhoid fever, leaving the elaboration of many

[1] Read before the New York County Medical Association on March 17, 1884.

details to the subsequent discussion, to which, I feel sure, you are all looking forward with eagerness.

It seems scarcely pertinent to allude to the prophylactic treatment, inasmuch as its nature is so readily deducible from the paper to which we listened with such interest at our last meeting.

I shall not occupy your time with any allusions to the subjects of sanitary plumbing and drainage, consideration of them having been so recently brought to your notice. As physicians, it becomes our imperative duty to prevent drains from becoming infected, by properly disinfecting all the discharges from typhoid fever patients immediately upon their being passed into the bedpan. Perhaps the best disinfectant to use, considering its cheapness and efficiency, is corrosive sublimate. It possesses the advantages of being cheaper and more effective than carbolic acid for this purpose, and it does not stain the bedclothes as does the solution of sulphate of iron. We know that the stools of typhoid fever patients are not infective immediately upon their being passed, but observations are still wanting to determine the exact time at which they become so. It is known that the disease has been spread by stools that have been kept twelve hours for the inspection of the attending physician and then promptly disinfected, but more definite information than this is still lacking, so far as I am aware. The length of time that the stools retain their efficiency as bearers of the contagion seems to be practically indefinite. Two years after the burial of fever stools in a dung-heap several men engaged in removing the dung-heap sickened with the disease. The danger of infecting drains in the post-mortem room is one not commonly considered, but it is certainly important to disinfect the intestinal contents upon the autopsy table before allowing them to reach the sewer. I am not aware that the disease has ever been spread by neglect to observe this precaution, but it seems fair to suppose that it might thus be spread.

After the disease has been contracted our first precaution should be to put the patient to bed at once, and keep him continuously there until convalescence has been fully established. The evil effects of a neglect of this measure are seen with unfortunate frequency in our hospitals, it being a matter of common observation with hospital physicians that cases coming under treatment late in the disease are more liable to exhibit aggravated conditions of meteorism, gurgling, tenderness, diarrhœa, bronchitis, pneumonia, buboes, boils, as well as increased tendency to relapse, to prolonged duration and all the severe complications, and to death, than are those who come under medical care early in the disease. These facts are well shown by an analysis of cases in the reports of St. Bartholomew's Hospital for the year 1882.

The hygiene of the bedchamber next claims our attention. This should, if possible, be large and well ventilated, and should contain two beds that may both be utilized by the patient. The temperature of the room should never be high if it can be avoided, and the patient's covering should be as light as is consistent with his comfort. High temperature of the atmosphere has been shown to aggravate a fever patient's condition, and we see higher degrees of fever and greater mortality in this disease during the summer than at other seasons. All external irritation should be avoided, such as strong light, noises, conversation, and all mental and physical excitement. The service must be quiet and unobtrusive. The patients must never be needlessly opposed, but must be humored in little things, so far as they are not inconsistent with our treatment. A delirious patient must not be forcibly restrained, but must be soothed and quieted in such a manner as every nurse with tact and discrimination understands. I well remember a patient whom I left one day in excellent general condition, but mildly delirious, during the second week of his disease. At night his delirium increased, and the house physician—one of the most efficient house physicians that I have ever had the good fortune to meet—found it necessary to have him restrained by attendants. The services of these attendants were more forcible than efficient, and after midnight in an encounter with them he succeeded in getting out of bed and fell, striking his head rather forcibly upon a hard floor. This seemed to render him furiously maniacal, and he died, exhausted, before daylight. A little more morphine, a large dose of brandy, a little tact, judgment, and good feeling on the part of the attendants might have saved this man's life. In a disease like this, in which trifles seem so often to turn the scale, one cannot be too careful to seize every possible advantage, however trifling, and turn it to good account.

Fever patients generally submit willingly to the taking of their temperature, and I have rarely encountered any objection to taking the temperature in the rectum, which is certainly the best situation for the purpose. English writers seem to have found it difficult or impossible to do this, strange as it may seem to us, and they write in an envious strain of the advantages possessed by continental observers in this respect.

Liebermeister and Friedreich have used calomel in the first week of the disease in doses of seven and a half grains, three or four times a day. They assert that the diarrhœa, which at first is increased by calomel, soon becomes less than before, and that this method of treatment, if undertaken early and systematically, seems to control the duration of the disease, lower the temperature, and lessen the mortality. Possibly this drug may remove some of the infecting material from the alimentary canal, and thus limit its power of producing local inflammatory changes. It is also asserted on high authority that the administration of three or four drops in a glass of water of a solution made up of one part of iodine, two parts of iodide of potash, and ten parts of water, if long kept up will lessen the mortality without marked influence on special symptoms. I have no personal experience with these methods of treatment, but inasmuch as they come to us from authority which we all must recognize, it seems right that they should be given a thorough trial. Doubtless, those who are to follow me this evening can bear testimony as regards this treatment.

The appetite is usually much impaired, and there can be no doubt that the powers of digestion and assimilation are markedly interfered with; but Pavy and Hoppe-Seyler have shown that an active digestive fluid can be prepared from the stomachs of animals in a state of fever. The digestive power varies in fever as it does in health in different individuals, and although some patients may be able to digest beefsteaks—as was the case with a patient of Heubner's, to whom he administered them throughout a severe attack of typhoid fever—there is little doubt that the average patients are unable to do so. Much of the inability to take food in fever is due to the partial or complete arrest of the secretion of saliva and the consequent dryness of the mouth. I have seen a patient's general condition improved by keeping his lips well smeared with vaseline and his mouth frequently moistened by teaspoonful doses of cold water. We should be careful to give an adequate amount of water throughout the disease, and, of course, the desire of patients is, in some conditions, wholly unsafe as a guide in reference to the quantity.

Experience teaches that our main reliance during the pyretic period must be upon milk, and we know that an adult patient will usually do fairly well if he is able to retain and assimilate about two quarts of it a day. Too much reliance cannot be placed upon the stimulating effects of the salts and extractive matters of meat-broths, as seen in their occasional administration. Their effects are of value upon the heart and central nervous system, as are also, in some cases, coffee, tea, and barley-water; but we must look to milk, peptonized or not, as our chief or only food. Rectal alimentation must occasionally be resorted to if the stomach prove irritable; but it must be our constant endeavor to avoid this complication by administering the food in small quantities, and not oftener than once in two or three hours. Two years ago it was my privilege to watch a case of typhoid fever through its entire course and a subsequent relapse, in which milk was not administered at all; in fact, in which substantially no treatment was resorted to. The patient was a pampered child of wealthy parents, always indulged and always self-willed, in whom the various traits developed by utter lack of training, seemed exaggerated by the removal of the slight inhibitory influences to which he was pleased to subject them in health. He would do nothing that it did not please him to do at the moment, nor would he allow anything to be done for him that did not suit his fancy. He resisted all efforts at reduction of his temperature by cold affusions, all efforts at rectal alimentation, and absolutely refused to take anything in the way of food, except beef-juice and lager beer. Occasionally, in my absence, his mother gave him bits of cracker and fruit. On one occasion he prevailed upon her to give him a large banana, which she told me he ate with relish. His struggles against sponging were such that it seemed to me injudicious to insist upon it, and I had the satisfaction, for the first time in my life, of watching a prolonged and well-marked case of typhoid fever substantially untreated through its entire course. His temperature remained between 102.5° and 104.5° for nearly two weeks, but he finally convalesced and made a complete, though tardy, recovery.

As to the use of spirits, we find the teaching of writers widely different. My own plan is to administer it early in the disease only to drunkards or those always habituated to it in large amounts. My belief is that many cases never need alcohol at all; but that a majority are benefited by it in the latter part of the second and third weeks, and often later. It seems to me that the tendency in New York is to begin the administration of alcohol too early, and to measure its amount rather by the actual quantity given than by the effect produced. The pulse and tongue, and the nervous symptoms should be our guides, and of these chiefly the pulse. If the heart's action become feeble and remain so, alcohol is indicated, and the amount to be given can only be measured by the effect produced. In some cases a few ounces of whiskey, in others nearly a quart in the twenty-four hours may be required. Digitalis is often of use under these circumstances.

As the disease subsides, we are compelled to determine exactly when a return to solid food may be allowed; and to ascertain how to answer this question, we must ask ourselves another, namely, What dangers do we encounter by administering solid food during the fever and immediately after its cessation? This depends much upon the character of the food employed. During the progress of the fever, stomach digestion is certainly much interfered with. It has been shown that in dogs affected with septicæmic fever the digestive fluid obtained from the stomach was far inferior in its powers of digestion to that of healthy animals; but that if hydrochloric acid were added, then the digestive powers were equal to those of health. This corresponds with a clinical observation that was made in one of Prof. Kussmaul's wards while I was a student of medicine in the University of Strassburg. The stomach of a man who was under treatment for chronic gastritis was being daily washed out, and the washings were carefully examined in the laboratory of Hoppe-Seyler from day to day. While under treatment of this kind, the man contracted typhoid fever in the hospital, and immediately on the temperature rising above the normal, all trace of free acid disappeared from the washings of his stomach. These experimental facts coincide with the results of clinical experience, and teach us that acids are often indicated for fever patients, and that purely albuminous food is not well borne in fever; but are there any facts which justify us in withholding such food after the temperature has become normal? We have been accustomed to hear that an early return to solid food is liable to produce a relapse; and this has been taken up and repeated by writer after writer, until at present many of us accept it without question. So far as I can learn, there is no clinical evidence in support of such a view. The statistics of a recent epidemic in London, as shown by the cases treated at St. Bartholomew's Hospital, bear strong testimony against this view.

There can be no question that solid food, passing undigested over the ulcers before they have lost

their sloughs and begun to granulate, has produced dangerous complications, such as perforation and hemorrhage; but after the base of the ulceration is covered by granulations, even this danger is removed. I am well aware of the fact that there are no signs upon which we can rely to indicate the depth, size, or general condition of the ulcers. Muscular twitching, of which so much has been said, is not a sign of ulceration at all, it being often absent in cases which go on to perforation, and being less frequent in typhoid fever than in typhus, in which latter disease, as we know, there are no ulcers at all. In view of all these possibilities, however, can there be any objection to allowing a little meat or egg or other food which will be digested *in the stomach* as soon as the fever has subsided and the gastric juice has again become capable of performing its function? I think not; and for some years it has been my practice to allow small quantities of finely divided meat—chiefly beef—as soon as the temperature has become normal. Thus far I have seen no harm result, and I think, on the contrary, that convalescence has been thus accelerated, and the patient's comfort promoted. My attention was first directed to this by an experience which occurred some years since in this wise: An assistant in my laboratory, a third-year medical student, contracted typhoid fever, and was treated in one of the wards of a well-known hospital. After his recovery, he assured me that he returned to solid food two weeks before the physicians were aware of the fact; and in response to further questioning from me, he told me that one of the kitchen-maids took pity upon him in his starving condition, and brought him secretly solid food of various kinds from the kitchen. Although aware of the danger of eating it, his hunger was so great that he was unable to restrain himself, and he partook freely without anything but advantage, the doctor who had him in charge meanwhile assuring him that only his rigid abstinence from everything except milk could have brought about so rapid a convalescence.

Cayley relates a similar case in his very valuable Croonian Lectures on typhoid fever, delivered before the Royal College of Physicians in London in 1880—lectures upon which I have not hesitated to draw largely to-night, deeming it useful to bring to your notice valuable testimony from all available sources upon this very important subject. The case to which Cayley alludes was that of a boy, about fourteen years of age, who passed through a severe attack of typhoid fever under his care in the Middlesex Hospital, and whose appetite returned before the temperature became normal. He continued to be restricted to liquid food. He complained to his mother, who remonstrated with the physicians. Cayley endeavored to explain to her the danger of beginning solid food too soon, to which she replied that she would rather see her boy die of fever than starvation. She accordingly took him home, stuffed him with solid food, and he recovered rapidly—much sooner, Cayley thought, than if he had remained in the hospital on restricted diet.

In selecting the solid food to be first administered to a convalescent from typhoid fever, one should of course select, as I have already suggested, a food which can be digested in the stomach. Whether the stomach is capable of digestion or not, the patient's desire for food and his general condition must help us to determine; but what possible harm can come to a granulating ulcer in the intestine by administering beef in small quantities to a patient whose pylorus it is not going to pass?

Of the administration of beef peptones in typhoid fever I have no personal experience. They are recommended by high authority, and it is to be hoped that we may learn something of their utility to-night from those who are present and have used them. I can testify to the efficiency of condensed milk as a food for these patients, having treated many cases under circumstances in which fresh milk was not obtainable.

Let us pass for a few moments to the consideration of the fever as a symptom.

As a rule, we clinicians are prone to disregard the evil effects of prolonged high temperature upon the various organs and tissues of the body, and thus to underestimate the importance of interfering with this symptom, even though we may be quite unable to cope with its cause. Observation at post-mortem examinations teaches us that extensive and serious parenchymatous changes occur throughout the body as a result of the febrile process, either a long-continued fever which has not necessarily been very high, or a fever of short duration but of high grade. It is my belief, founded on numerous post-mortem examinations, that the patient never reaches the end of the third week of an average typhoid fever without the muscular wall of his heart having undergone in places a granulo-fatty change. We find the muscular fibres in many situations in the organ so filled with granular material that the transverse striæ are obscured altogether, and in some cases minute drops of fat are distinctly visible. A similar change under similar circumstances is frequently seen in the glandular cells of the pancreas, salivary glands, liver, kidneys, gastric tubules, and the voluntary muscular fibre. Another change in the voluntary muscles, known as the waxy or vitreous change, was first described by Zenker. All the voluntary muscles are liable to it, including the diaphragm, in which latter situation its seriousness need not be pointed out. Vascular changes also occur, as is evidenced by minute hemorrhages beneath the serous membranes seen so frequently. Such changes, of course, are not peculiar to typhoid fever. I have frequently found them in other conditions of high temperature, even after high temperature of comparatively short duration, as in cases of sunstroke. These lesions, then, are the result of the febrile process, whatever be the essential lesions of which that process may happen to be a symptom. In connection with this subject, Cayley observes as follows:

"It can hardly be doubted that the result of a large number, if not the majority, of fatal cases of typhoid fever is due to these changes. If we exclude those deaths which are directly caused by the intestinal lesions, as perforation and hemorrhage, which, after all, are the minority, the remainder

may for the most part be ascribed to failure of the heart and central nervous system. And of these, failure of the heart, with its concomitant congestion of the lungs, plays the most important part."

Max Schultze has demonstrated, under the microscope, the injurious effects of high temperature upon living cells.

There is a marked diminution in the number of red blood-cells in fever; and the febrile wasting of the body has been estimated by so good an observer as Leyden, in Berlin, in some cases at an average daily loss of seven parts per thousand of the entire weight, this being not merely the wasting of inanition, but being due largely to the increased consumption of the febrile process.

In a paper on the treatment of typhoid fever, one is hardly warranted in devoting so much time to the consideration of pathological changes except perhaps as a means of emphasizing the importance of certain methods of treatment to be presently advocated.

The various clinical symptoms which indicate the presence of these parenchymatous changes are too well known to us all to require more than passing allusion in this paper.

Lauder Brunton, in his valuable lectures on pharmacology and therapeutics, gives us, in words upon which it would be difficult to improve, the pharmacologist's view of these parenchymatous changes. He says: "When the power of the blood to convey oxygen is lessened by diminution of its red corpuscles, the consequent want of oxidation leads to the accumulation of fat frequently noticed in anæmia; and a tendency to obesity frequently appears after severe hemorrhage. The pathology of fatty degeneration indicates its treatment, etc. . . . But there is one way of influencing tissue-change which I must not forget. By simply keeping an animal in a hot chamber for a little while, the tissues decompose more rapidly, and evidence of their waste is to be found in the urine as increased urea. Quicker decomposition is followed by increased combustion, and the temperature of the body rises. Now begins a vicious circle; for the higher temperature itself quickens tissue-change, and the fire supplies itself with fuel. The heat, too, stimulates the cardiac ganglia, quickens the heart, dilates the vessels, and accelerates the circulation. Acting on the respiratory centre, it quickens the respiration, increases the supply of oxygen to the body, and thus fans the flame. But, quick as the respiration may be, rapid as is the circulation of arterial blood, it is, as Wickham Legg has shown, insufficient in many instances to keep pace with the decomposition of the albuminous tissues, the products of waste accumulate, and we find them in the fatty heart of fever patients and in the livers of Strassburg geese. Now we clearly see that, whatever may have led to the increased tissue decomposition and combustion in the first instance, the high temperature itself is a cause of mischief, and must be reduced."

Having thus reminded you of the varied lesions resulting from the febrile process, let me ask your consideration for a few moments of some statistics showing the results of treatment on the so-called expectant plan, which is so common here in New York, before proceeding to advocate the adoption of the antipyretic method.

Statistics of results of expectant treatment:

	Cases.	Per cent. deaths.
London fever hospital in 20 years,	8,000	18.9
" " " 9 "	569	15.9
Pauper hospital at Homerton,	1,509	16.8

Principal general hospitals in London during the ten or twelve years prior to 1880:

	Cases.	Per cent deaths.
St. George's,	387	19.6
Guy's,	295	19.3
University,	163	17.7
St. Bartholomew's,	635	16.3
St. Thomas's,	445	15.7
Middlesex,	461	15.6
King's College,	318	12.2
Total for hospitals of London,	14,125	17.8

	Cases.	Per cent. deaths.
General hospital in Vienna,	17,000	22.5
Hospital at Basle, in Switzerland,	1,718	27.3

Generally in principal Continental hospitals mortality varied from 16 per cent. to 25 per cent.

The English Army gives these results for six years ending 1877:

	Cases.	Deaths.	Per cent. mortality.
Home service,	545	131	24.0
Foreign service,	1,383	564	40.7
English Navy for the six years ending 1878,	414	110	25.5

Jaccoud recounted, as will be seen later, last year, at the Academy of Medicine in Paris, that he had collected 80,140 cases treated in Europe on the expectant plan, with a mortality of 19.23 per cent.

A glance at the statistics of our own army is instructive in this respect. I have taken the following facts from the *Medical and Surgical History of the War of the Rebellion:*

White Troops.	Cases.	Deaths.
During the year ending June 30, 1862,	21,965	5,648
" " " " 1863,	32,166	10,483
" " " " 1864,	10,116	4,475
" " " " 1865,	9,739	5,798
" " " " 1866,	1,285	635

This gives a total for these five years in our white troops of 75,368 cases of typhoid fever, with 27,056 deaths, this being a mortality of 35.9 per cent.

During the years 1864, '65, and '66, among our negro troops there were 4094 cases, with 2280 deaths, this being a mortality of 55.6 per cent.

We have thus a most painful showing from all parts of the world, the worst record of all coming from our own army. The mortality from this disease during the four years of war among our white troops was 35.6 per cent. During the year following the war in the same troops the mortality among those suffering from this disease was 49 per cent.

It must be borne in mind that the lower mortality in many of the London Hospitals quoted above is to be explained by the introduction into many of them of a modified form of the antipyretic

treatment, a faint semblance of which exists in some of our own hospitals.

In a paper by Dr. Francis Delafield, published in the *Medical Record* for November 17, 1883, some statistics of our own hospitals are given. Between January, 1877, and October, 1883, there occurred 1305 cases in the following hospitals: Bellevue, Riverside, Roosevelt, New York, St. Luke's, St. Vincent's, St. Francis's, and Mt. Sinai. The percentage of mortality, estimated by years, varied between a minimum of 20.1 per cent., in 1879, and a maximum of 30 per cent., in 1880. As showing the results in the different institutions, it appears that the lowest rate of mortality during these years occurred in the Mt. Sinai Hospital, where it was 17.1 per cent., and the highest in the Roosevelt Hospital, where it reached the rate of 36.8 per cent. In this very interesting paper is given a brief summary of the treatment in these various institutions which has produced these results. From this I extract the following:

"In the New York Hospital many patients are simply put on a milk diet, with the addition of a moderate amount of whiskey, and no other treatment is used. Peptonized milk instead of ordinary milk is thought to be of service. For high temperature, the body is sponged with equal parts of alcohol and water, and sometimes the fluid extract of eucalyptus is given in fifteen-minim doses. Quinine is not much used. Tympanites is treated with turpentine internally, and in stupes over the abdomen. Opium is given when there is hemorrhage from the bowels, or excessive diarrhœa.

"At St. Luke's Hospital, the treatment is the same, except that quinine is sometimes employed to reduce the temperature, and ergotine hypodermically for intestinal hemorrhage. Either opium or chloral is used to control restlessness and sleeplessness.

"At St. Francis's Hospital, if the cases are seen early in the disease, large doses of calomel are given, with the idea of aborting the disease. Quinine is given in large doses to most of the patients. The salicylate of soda or the benzoate of soda is given by some of the physicians throughout the disease. Cold water, in any form, to reduce the temperature, is but very little used. A solution of the acetate of alumina is given to nearly all the patients, to prevent or control the diarrhœa.

"At St. Vincent's Hospital quinine, in doses of two grains every two hours, is given to control the temperature. Cold water is not employed. Opium is used with diarrhœa and intestinal hemorrhage. At the Mt. Sinai Hospital quinine in large doses is given to nearly all the patients. Cold water is not much used, but sometimes the patients are sponged off.

"At Bellevue Hospital the treatment varies in the different divisions. In one division the peptonized milk is much used. Quinine in large doses is given when the temperature reaches 103°, and sponging is also sometimes used. Opium, the bromides, and cold to the head are used for the restlessness. In another division quinine, in moderate doses, is given to most of the patients. For temperature over 103° sponging with cold water, or the Kibbee Cot and sprinkling with cold water are used. Opium is given when needed. In another division carbolic acid (gt. j) and tincture of iodine (gtt. ij) are given every two hours early in the disease. Quinine in ten-grain doses every half hour is given to reduce the temperature. Sponging with cold water is sometimes used. Opium is employed for severe diarrhœa. In another division, occasional sponging, and whiskey and opium when required, are the only treatment.

"At the Roosevelt Hospital, full bathing has been tried in many cases, but now cold sponging is more used. Bismuth and pepsin are given to many of the patients. In all the hospitals, milk, either simple or peptonized, is the regular diet of the patients."

And now, let me ask, Have we reason to be satisfied with the expectant treatment of typhoid fever? Is the mortality, as shown in the figures taken from the books of our own hospitals, low enough to warrant us in being contented with the results of the various modifications of the expectant treatment in use here? Have we possibly among us any who think, with Skoda, that it makes no difference whether typhoid fever patients be treated or not? Before we endeavor, by discussion, to elicit answers to these questions, let me offer a few facts and figures from other sources, giving the results of antipyretic treatment.

(To be concluded.)

PELLETIERINE, A NEW TÆNIFUGE.

By JOHN L. DICKEY, A.M., M.D.,
of Wheeling, West Virginia.

A recent valuable addition to the remedies used against tænia is pelletierine. It is an alkaloid derived from the root-bark and stem-bark of granatum. It was discovered in 1878 by Tanret and was named in honor of another eminent French chemist, Pelletier.

The powder is grayish-yellow in color. The dose is given by one authority as two and a half grains, by another, fifteen. The preparation most largely used is gotten up in a proprietary form by Tanret, under the name of "Tanret's Pelletierine." It is of the color and consistence of maple syrup, and has a sweet and pleasant, but slightly astringent taste. Each bottle contains an ounce, which is the adult dose. An objection to it is the price, three dollars a bottle. Following is a case in which it was used:

Percy M., æt. 10, had been suffering from a tapeworm for three or four years. While the family lived in Cleveland he had been treated by several physicians at different times, large portions of the worm had been expelled, but the head still remained. Over a year ago the family removed to this city and the boy had been treated by a physician, who succeeded in getting large sections of the worm, but not the head. The case came into my hands, and half a bottle of "Tanret's Pelletierine" was administered on an empty stomach, but owing to the impossibility of getting the boy to take a sufficient cathartic we failed to get the whole worm. Several

weeks later, another and more successful attempt was made.

The boy was given a glass of milk only for supper, and the next morning for breakfast he took another glass of milk containing the remainder of the bottle of pelletierine, about half an ounce, without knowing he had taken any medicine. Half an hour later he was given a full dose of compound cathartic elixir, but his sensitive stomach rebelled and the elixir was vomited. A still more palatable cathartic was given, in the shape of half a bottle of citrate of magnesia, and at two o'clock I called and found him on the *pot de chambre*, having passed a large, watery stool and about half of the worm. Without removing him or breaking off the worm, I gave him an enema of about twenty ounces of tepid water and soap-suds, containing a drachm of common table salt. In a few minutes the injection was expelled with more of the worm, and taking hold of it and drawing it gently away, hand over hand, the whole worm was soon withdrawn, the small head and suckers being clearly visible to the naked eye. It measured about sixteen feet in length. Under a microscope, the four suckers and central fringe of hooklets proved it to be a tænia solium.

The advantages of this preparation of pelletierine over other tænifuges are its quick action, and its pleasant taste and easy administration. I had seen it successfully used last winter by Prof. Da Costa at the Jefferson College Hospital clinic, in a case that had resisted all the well-known remedies.

Giving the injection and gently drawing away the worm I consider important parts of the treatment in the above-mentioned case. It is probable that very often tænia are expelled as far as the lower bowel and that a part of the tangled mass is retained by the sphincter, thus giving the head a chance to re-attach itself. The worm did not once break in drawing on it, but was tough and elastic. After a few minutes' exposure to the air, however, it became brittle and broke easily.

MEDICAL PROGRESS.

The Climatic Treatment of Phthisis.—In a paper on this subject, read before the Ulster Medical Society, Dr. James Alex. Lindsay says that there are several cases in which the climatic treatment is plainly inadmissible.

1. In acute tuberculosis. Here no treatment is of even temporary avail, and the rapid prostration of the patient makes a resort to travel quite out of the question.

2. During acute exacerbations of the chronic malady. Here the wise treatment is to avoid all causes of excitement and irritation, to soothe the patient, and to wait until the disease shall again resume its chronic character.

3. Where the patient's means are insufficient to enable him to travel with reasonable comfort, or where there is an idiosyncrasy which renders travel peculiarly distasteful and irritating.

In regard to favorable cases:

1. Those which approach the remittent type are peculiarly favorable for climatic treatment.

2. The milder constitutional symptoms are, in proportion to the local pulmonary mischief, the more hopeful is the climatic treatment, and *vice versâ*.

3. It is important to inquire whether resort has ever before been had to travel, and with what results. Patients who are braced and stimulated by change of scene, and who possess much mental elasticity, are more likely to gain advantage than those who are depressed and disheartened by absence from home and the association of friends.—*Dublin Journ. of Med. Sci.*, February, 1884.

Double Operation for Empyema.—Brauser reports the case of a boy, æt. 3 years, who had pneumonia and double exudative pleurisy after scarlet fever. Pus having been found by the exploring needle, the right side was punctured and pus evacuated. Ten days afterward the same operation was performed on the left side and a quantity of pus evacuated. The child was well in two months.—*Centralbl. für Chirurg.*, February 23, 1884.

Antagonism of Paraldehyde and Strychnia.—At the meeting of the Société des Hôpitaux, on February 8th, Prof. Dujardin-Beaumetz reported the results of his experiments on this subject.

His experiments were made on rabbits. He has given to these animals twenty-five times as much as a fatal dose of strychnine, without causing death, after having previously given paraldehyde—there were only a few slight convulsions. These results are similar to those obtained by Luton in his experiments as to the antagonism between strychnia and alcohol. It is well known that Luton injected, in a case of nervous derangement due to alcohol, one-thirteenth of a grain of sulphate of strychnine in the morning, and repeated this in the evening, if the patient was not sensibly better. The antagonism between strychnine and alcohol was observed by Morray, in England, before the experiments of Luton. The latter has attempted to show that strychnia is an absolute antagonist to alcohol, for, while it causes the nervous troubles of alcoholism to disappear, it has no influence on the gastric and other symptoms of alcoholic intoxication. In the same way, Claude Bernard showed that large doses of strychnia had no influence on etherized animals. M. Dujardin-Beaumetz stated that Morselli had made experiments with paraldehyde and strychnia on dogs, with the same results as obtained by himself with rabbits. [The first experiments on this subject were made by Cervello, for an account of which see The Medical News, October 27, 1883.]—*Progrès Méd.*, February 16, 1884.

Treatment of Hernia by Peritoneal and Intercolumnar Suture.—In a paper on this subject read before the Academy of Medicine in Ireland, on January 11th, Mr. William Stokes describes an operation which consists in the deep insertion through the opened neck of the sac, and close up to the external abdominal ring, of a carbolized catgut suture or sutures, according to the size, width, and depth of the neck, and this is followed by the approximation or closure of the canal and pillars of the ring by the insertion of two or more sutures of a stronger and more durable material, such as chromicized catgut, carbolized

silk, or silver wire. It is, in fact, a dual system of suture, one being peritoneal and the other intercolumnar. He believes that in the great majority of cases this procedure will be found to be attended with satisfactory results, always provided that rigid Listerian antiseptic precautions are taken during and subsequent to the operation.—*Dublin Journ. Med. Sci.*, Feb. 1884.

NEPHRORRHAPHY.—On February 11, PROF. ANDREA CECCHERELLI performed this operation, in the Surgical Clinic in Parma, for painful movable kidney. This is the ninth operation of this kind, and the second which has been performed in Italy. After thirty-six hours there was no fever.—*Gazz. degli Ospitali*, February 24, 1884.

INTESTINAL RESECTION AND INTESTINAL SUTURE.—REICHEL, at the close of a report of several cases of resection and suture of the intestine, draws the following conclusions:

1. Sutures should only be placed in healthy intestinal structure, and the gut should be free of contents.

2. The indications for resection of the intestine are, gangrenous hernia, intestinal tumors and wounds.

3. At the conclusion of the operation the peritoneal cavity is to be closed by suture of the abdominal walls.

4. The sutured loop should be replaced entire, and then the abdominal cavity should be completely closed by sutures. Drainage of the peritoneal cavity, as well as fixation of the loop, is unnecessary and should not be used.

A most rigorous diet should always be enforced for the first few days after the operation.—*Centralbl. für Chirurg.*, February 9, 1884.

FRACTURE OF THE NAVICULAR BONE OF THE FOOT.—At the meeting of the Academy of Medicine in Ireland, on January 4, 1884, DR. BENNETT submitted two examples of fracture of the navicular bone, which he believed had not been heretofore described. The first and older of the two specimens came into his possession some years ago from the dissecting-room, so that of course he had no life-history of it, and it had since remained in the Museum of Trinity College. This year a second and more characteristic specimen of the injury came into his hands similarly, and without history. He at once observed its identity with the former example—in both the articular surface of the bone which receives the head of the astragalus presenting distinct evidence of united fracture, which traversed in a regular line the upper and outer part of the surface. Turning to the opposite articular surface, which supports the cuneiform bones, one is surprised to find only the most trivial traces of fracture marking the upper margin of the upper and outer part of the facet. In so thin a bone as the navicular, one would expect to find a close correspondence in the lines of fracture, no matter how arising, on its opposite faces; but it was evident that the planes of fracture originating in the hollow depression on the proximal surface had passed with extreme obliquity to the free margin, almost avoiding the distal surface. He concluded that the force which caused the injury in both cases was a degree of crushing which, if more strongly applied, would have produced dislocation of the head of the astragalus upwards and outwards. With the specimen last obtained he had the other tarsal bones, and exhibited them as proof that the injury in this case was limited to the navicular bone, the others being normal, except only the head of the astragalus, which showed slight trace of change in form, such as its articulation with a bone whose surface was altered by fracture would readily induce.—*Dublin Journ. of Med. Sci.*, February, 1884.

TREATMENT OF SINUSES BY THE INJECTION OF OIL OF TURPENTINE.—CECCHINI reports three cases in which the injection of spirits of turpentine into fistulous sinuses was successful. Believing that the non-closure of sinuses is often due to retention of pus, this being caused by the tendency of most of the injections used to coagulate the albumen with which they come in contact, Cecchini was induced to use turpentine on account of its not coagulating albumen, and also on account of its stimulating and diffusive properties. The cases reported were, two of fistula in ano, and one of fistula of the lower jaw.—*Gazz. degli Ospitali*, January 2, 1884.

MILIARY ANEURISMS OF THE STOMACH.—At the meeting of the Société des Hôpitaux, on Feb. 22d, M. GALLARD spoke of miliary aneurisms as causes of fatal hematemesis.

In 1875 he made researches on simple ulcer of the stomach, and in all the fatal cases he found an anatomical lesion large enough to account for the fatal issue. But in 1876 he encountered two cases of hematemesis, which caused sudden death, with no other lesion than ulceration of a miliary aneurism of one of the branches of the coronary artery. These cases appear to be unique. In January, 1884, he had a similar case—that of a man, æt. 48 years, who was brought to l'Hôtel Dieu on account of hemorrhage from the stomach. There were no special symptoms; the patient simply complained of loss of appetite, and slight gastric pains. Physical examination showed only distention of the stomach. In spite of rational, active treatment, the patient died the next day.

At the autopsy the intestinal tract was found filled with blood; the mucosa of the stomach was violaceous and slightly softened. In the greater curvature of the stomach, on the left near the cardiac orifice, was a small ovoid tumor, as large as an apricot, perforated at the top and on the line of a bloodvessel. There was no doubt that this was an aneurism. A single similar case was published in 1878, by Douglas Powell, in the *Transactions of the Anatomical Society of London.*—*L'Union Méd.*, February 26, 1884.

ABSCESS OF THE SPLEEN; ASPIRATION.—PARZEWSKI reports the case of a man, æt. 45 years, who, two years previously, had an attack of relapsing fever. Three weeks after his recovery he noticed a swelling on the left side, over the situation of the spleen. When an examination was made, Parzewski diagnosticated left pleurisy with effusion, and also found a fluctuating tumor over the spleen. Exploratory puncture with a Pravaz's syringe showed a dirty reddish-brown matter, containing altered blood-globules and detritus. In the course of five weeks three aspirations were made, by which about one pound and a half of the matter was withdrawn each time. The patient was finally cured.—*Centralbl. für Chirurg.*, February 23, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE. . . . . $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 29, 1884.

"CRANIOTOMY UPON THE LIVING FŒTUS IS NOT JUSTIFIABLE."

THIS is the title of the Presidential Address recently delivered before the Washington Obstetrical and Gynecological Society by DR. S. C. BUSEY. The discussion of this subject is peculiarly timely, since the tendency of obstetric literature has been to urge strongly the claims of the Cæsarean operation, and its modifications, to more favorable consideration than it has heretofore enjoyed. Of course, the subject is presented by Dr. Busey with earnestness and ability, but as to the conclusiveness of the argument, opinions will probably differ.

He holds that "If craniotomy is justifiable, science and the good of mankind demand that the limits of its application should be definitely fixed." Certainly all will agree to this statement, for a general truth—applicable to other operations as well—is expressed. In the greater consideration given of late to the use of the forceps, to turning, induction of premature labor, to symphysiotomy, to the Cæsarean operation and its substitutes, Dr. Busey sees presumptive evidence "of a widespread detestation of craniotomy." But, on the other hand, would it not be quite as just to say that the recent invention of such instruments as the basilyst of Simpson and the basiotribe of Tarnier is evidence that obstetricians recognize craniotomy as a necessary operation?

Again, the author commends the Cæsarean operation because "it may restore to women incapacitated by pelvic deformity the privilege and power of giving birth to an indefinite number of living children"—Lungren having proved that multiple operations are attended by a greatly lessened mortality—and he commends Porro's operation because it prevents subsequent pregnancies, and, therefore, no opportunity is given for craniotomies. But suppose women do not desire an indefinite number of living children, or again, suppose a woman, after having recovered from a Cæsarean operation, becoming pregnant again, chooses craniotomy, and the supposition is just as reasonable as the opposite, is there not an argument against the Cæsarean operation equal in force to that in favor of it?

Again, he states that "there is not, perhaps, living to-day a single obstetric authority of accepted repute who will claim the practicability of craniotomy in cases in which the conjugate is an inch and a half or less, and few hold it is justifiable when the diameter is two and a half inches or less." The statements of some living obstetric authorities do not fully sustain this position. According to Barnes, "craniotomy and cephalotripsy are the means of effecting delivery in cases in which labor at term is obstructed from disproportion, the pelvic contraction ranging from 3.25″ as a maximum, to 1.50″ as a minimum." Delore, referring to the conditions of application of the cephalotribe, says the limits of narrowing within which it can act efficiently are between 2.47 inches and 1.57. Professor Wasseige, in his work *Des Opérations Obstetricales*, Paris, 1881, refers to thirty-five cases of cephalotripsy he had done, with only six deaths; in only two of these could the fatal result be attributed to the operation, and four would have died no matter what operation had been performed; yet in one of the successful cases the conjugate was only one inch and a half. Pajot advises the cephalotribe in all cases of narrowing below two inches, if the instrument can be introduced; only when this introduction is impossible, the Cæsarean section.

In Dr. Godson's paper upon Porro's operation, published in the *British Medical Journal*, January 26, 1884, its distinguished author remarks, "I hope that the time is not far distant when Porro's operation may become one of selection, displacing, to a great extent, craniotomy." This seems a wiser and more practicable position than the one Dr. Busey has taken.

The general voice of the profession is expressed in the words of Dr. Barnes: "A law of humanity hallowed by every creed, and obeyed by every school, tells us where the hard alternative is set before us, that our first and paramount duty is to preserve the mother, even if it involve the sacrifice of the child." With this before us let one compare the table of Porro operations given by Dr. Godson with the result of cephalotripsy in the hands of Wasseige. Dr. Godson's table includes 134 cases, and the mortality of mothers was 55.97 per cent.

But in only 70 of these cases was the condition of the mother "favorable," and these 70 selected cases show a mortality of less than one in three. In Wasseige's cases of cephalotripsy there were 6 deaths in 35, that is, scarcely more than one in six. But 4 who died were unfavorable cases for any operation, and throwing out these, the mortality was less than one in fifteen. Admitting Wasseige's success as exceptional, we may take the results which Pajot had some years ago by his method of cephalotripsy, one death in four, and we still have a less maternal mortality than the best Porro operations. When we add to this professional view of the matter, the fact that women themselves will generally choose the sacrifice of their children rather than undergo any form of gastro-hysterotomy —and in such a matter as this the woman herself must where possible be given the deciding vote— the prospect of an entire abandonment of craniotomy is not encouraging.

RESPIRATORY THERAPEUTICS.

THE stimulus of the prevalent confidence in the Kochian doctrine of the parasitic origin of tuberculosis, has renewed one of those periodic devotions to inhalatory therapy which, since the time of the revered Hippocrates, have followed the discovery of novel gaseous compounds and elements, respirable and irrespirable; and of which the latest revival, a quarter of a century ago, still holds sway in the widespread use of medicated sprays in the treatment of affections of the air-passages.

The personal supervision requisite for effective medication by way of the respiratory tract demands more time than is usually bestowed on domiciliary visits to the sick; and to this may be attributed some of the disinclination of physicians to make use of the air-tract in the ordinary routine of practice. Hence, the method has received much less attention in America than in Europe, especially Continental Europe, where numerous resorts of easy access have been established for its systematic utilization. The great desideratum has been some economic plan of home-treatment, as a fair substitute for treatment at an inhalatorium. Many appliances have been constructed for the purpose. The majority of these being either inefficient, clumsy, or unsightly, they have not met with much favor; and this fact has prevented proper attention from being given to those which possess real merit.

That much good can be accomplished by resort to respiratory therapeutics is well known to those who have given them fair trial; good, too, in many instances, that cannot be accomplished by any other method of treatment. Thus, inspirations of slightly compressed air will distend unused air-cells far more thoroughly and safely than the most violent voluntary efforts; and do it, too, for the weak, as well as for the strong. They will often act mechanically as an expectorant, far more efficaciously than any drug, and, at the same time, improve the appetite instead of impairing it. In many cases of phthisis these results are simply invaluable. Expirations into rarefied air will exhaust emphysematous air-cells of much of their excess of residual air, and by relieving their tension will facilitate the return of elasticity to the lung tissue. This mechanical result alone will often cure asthma of recent standing in old subjects, and even cases of long standing in young subjects. The modifications in intrathoracic pressures, practicable by the use of slightly compressed or slightly rarefied air, are sufficient at times to overcome the mechanical impediments presented in certain valvular and other cardiac deficiencies, and thus favor the ultimate resumption of functions in partial abeyance.

Medicated airs, employed continuously or at intervals, overcome the fetor of bronchorrhœa, and pulmonary gangrene; soothe the irritability of diseased mucous membrane that provokes cough and prevents sleep; saturate the system medicinally with various volatile drugs; and thus do a great amount of good more readily than any other agents. They are the sole substitutes for a balsamic atmosphere within the reach of those who need it and cannot go where it is afforded by nature.

In fact, we cannot ignore the published records of the value of respiratory therapeutics, as collected in monographs and scattered in the journals; nor can we deny to inhalation a respectable position among the healing arts. Should the present impetus to the study of antiseptic inhalations help to place the entire method upon a more intelligent basis, and teach what can really be accomplished in its various modes of use, the revival will have been of service to medicine, even though it fail to find a safe weapon for destroying the dreaded bacillus tuberculosis.

SPURIOUS CYSTS OF THE BELLY DEPENDENT UPON DIFFUSE TUBERCULOSIS OF THE PERITONEUM.

IN the *Centralblatt für Chirurgie*, No. 6, 1884, PROF. KOENIG, of Göttingen, directs attention to a hitherto undescribed affection, which is interesting alike to the surgeon and the pathologist, and which consists of encysted serous exudations in the abdomen, the result of general tubercular peritonitis. The tumors thus formed, and as yet only observed in females, develop gradually, are mobile when small, but fixed when large and in contact with the inner surface of the abdomen, are the seat of undulating fluctuation, and are frequently multiple, smaller cysts being found in the vicinity of the largest one. They are met with at all periods

of life, not alone in subjects of other tubercular affections, but in those who are apparently free from such lesions elsewhere.

That these cases are not absolutely hopeless, is shown by the following example, which also affords a good illustration of the proper mode of treatment:

A previously healthy woman, thirty years of age, had observed for about three months a gradual enlargement of the abdomen, which soon became the seat of intense pain. The median portion of the belly was occupied, from the symphysis to the umbilicus, by a fluctuating, rather lax tumor, which lay in front of the intestines. A free incision disclosed behind the tubercular peritoneum a sac, filled with a slightly turbid, fibrinous fluid, the limiting tubercular membrane of which was excised, and the entire resulting cavity sprinkled with iodoform, after having been washed out with a solution of carbolic acid. A drainage-tube having been inserted, the wound was closed in the usual manner. The recovery was rapid, without any particular signs of reaction, and the woman was perfectly well and attending to her work two years after the operation.

TOXIC EFFECTS OF BONJEAN'S ERGOTIN.

The large use of ergot at the present time invests the subject of its toxic action with peculiar interest. Dr. Debierre, Agrégé of the Lyons Faculty of Medicine, has lately published an instructive example of chronic poisoning, and makes it the text of some valuable observations on the physiological actions of ergot. The so-called *ergotin* of Bonjean is not only an extract of ergot, but a concentrated extract. The patient, a woman of twenty-five, suffering from menorrhagia, took, in the morning, a quantity estimated at seventy-five to ninety grains of the ergotin. The hemorrhage was arrested, and did not recur. At noon, the patient ate some food with a good appetite, and for six hours after the ingestion of the ergot there were no symptoms of toxic action; then, however, severe pains began to be felt in the hypogastric region. A sense of suffocation came on, and urgent demand for more air was made. The mucous membrane of the mouth and throat became exceedingly dry, and the skin was dry, tense, and retracted. The abdominal distress extended to the chest, and severe pain was felt along the course of the œsophagus and bronchi: it had a rasping and constrictive character. In about four hours after the beginning of the pains, tonic and clonic convulsive shocks, having some resemblance to epileptic seizures, were experienced. The respiration was accelerated to 50 per minute, but continued shallow; the pulse was small, soft, and had fallen to 50; and the temperature declined to about half a degree below the normal standard. The surface became pale, cold, and benumbed, and there was a subjective sensation as if the skin were compressing the body with a vice-like grasp. Sensibility to touch, to pain, and to cold and heat declined, and the tips of the fingers, the lips and the tongue, and the bottoms of the feet became anæsthetized, and gradually the anæsthesia extended over the whole body. Vertigo, tinnitus aurium, obscurity of vision, and mental hebetude were experienced; and these nervous disturbances culminated in the epileptiform seizures above referred to.

The restlessness, anxiety, and depression were so considerable, that Dr. Debierre decided to administer ether subcutaneously. The good effects seemed to be little short of magical. The pain ceased, the respiration became calm and easy, the pulse increased in strength and volume, the dyspnœa was no longer experienced, the surface grew warm, and the nervous disturbance subsided. During the following night there was some recurrence of the pain, the dyspnœa, and the præcordial anxiety, but not of the convulsive phenomena. Ether was again given subcutaneously, and to some extent by inhalation; coffee was administered freely, and two doses of chloral, aggregating forty-six grains, were also given. By these means, a decided amelioration of all the symptoms was effected by morning. During the second day, the anæsthesia persisted in a less degree, there were occasional attacks of muscular spasm and of pain, and a strong sense of lassitude was experienced. On the third day of the poisoning, there were still occasional attacks of spasm, and the pectoral and abdominal pains now and then occurred, especially when food was swallowed. On the fourth day the principal symptoms had greatly lessened; vision became clear, the heaviness of the head and the singing of the ears subsided, the constrictive pains in the stomach and abdomen abated materially, the general sensibility returned to the normal standard, and the sense of exhaustion had nearly gone. During the course of the treatment which had effected these results, two drachms and a half of chloral and three drachms of ether were administered. It is an interesting fact, that the most effective means of relief to the symptoms had been the subcutaneous injection of ether. A more exact antagonism has been shown to exist between amyl nitrite and ergot, but this fact was not known, or was not utilized.

The following conclusions seem to be properly deducible from the experience in Dr. Debierre's case:

First, as to the rate of absorption. So many hours elapsed before the symptoms began, that it would seem to confirm the view which maintains that absorption of such medicaments does not occur in the stomach, but in the intestines. In favor of this theory are quoted the experiments of Bouley and

Colin, who found that even large doses of strychnine introduced into the stomach of the horse did not have a toxic effect until the ligature which had been put around the pylorus was divided. In Dr. Debierre's case, the ergot remained a number of hours in the stomach before absorption occurred, contrary to the usually accepted opinion that its action begins in about twenty minutes, and ends in an hour or two.

Second, as to the effects of ergot on the circulation. All the symptoms referable to the circulation indicate that ergot both slows and enfeebles the heart, and contracts the arterioles, but does not increase the vascular tension. This result is in accord with the experiments of Yvon and Tanret, who found that ergot causes contraction of the vessels, after division of the sympathetic, whence they conclude that it acts directly on the organic muscular fibre.

Third, as regards its effects on the nervous system. The cramps and convulsive phenomena, but especially the violent pectoral and abdominal pains, signify spasm of the muscular fibre of the vessels of the bronchi and of the intestinal canal, respectively. To the same action must be attributed the pallor and coldness of the surface, and the subjective sense of chilliness, and, no doubt, also the anæsthesia. The action of ergot on the unstriped muscular fibre admitted, all of the symptoms, indeed, produced by this agent are readily explicable. The slowing of the heart and the diminished acuity of vision, under these circumstances, mean lessened blood-supply to the cardiac motor ganglia and to the retina, respectively. The same action extended to the brain, the observed cerebral symptoms become a necessary result. This theory does not imply, however, as has been heretofore maintained, that ergot stimulates the ganglia and fibres of the vasomotor system.

ELYTROTOMY IN EXTRAUTERINE PREGNANCY.

THE operation of elytrotomy in extrauterine pregnancy is so infrequently performed, that the successful case reported at a late meeting of the Academy of Medicine of Paris, by PINARD, cannot fail to interest our readers. The subject was thirty-one years old, and became pregnant for the third time. This pregnancy was marked by acute pains in the abdomen, inability to engage in her usual avocations, and necessity for remaining recumbent. At the end of pregnancy the ordinary symptoms of labor, though in a less degree, occurred; these passing away, were followed by enlargement of the mammary glands, as after normal labor. At the end of two months the abdominal tumor, which had remained stationary from the time of the symptoms of labor, rapidly doubled its size, and an examination showed that this increase was due to an accumulation of liquid within it; simultaneously acute pains in the abdomen, difficulty in micturition and in defecation, and grave general symptoms appeared. Tarnier being consulted at this time, advised the operation by the vagina, because of the great prominence which the tumor offered in the posterior vaginal cul-de-sac. Accordingly, Pinard incised the salient part of the vagina, and without any difficulty removed the fœtus; the placenta was adherent, and no attempt was made to remove it, but the cystic cavity was injected every two hours with a solution of corrosive sublimate, 1 to 2000. These injections were continued for eighteen days with the same regularity, when the spontaneous detachment of the placenta and its discharge occurred; meantime there was not the slightest indication of mercurial poisoning, or of septic infection. The patient was quite well in a month, showing only a long, red cicatrix in the vagina.

It is stated that only one other case is known presenting the same conditions, and followed by success. But we need but refer to Deschamp's monograph upon extrauterine pregnancy, Paris, 1880, to find two similar cases; one occurring to Schroeder, and the other to an English practitioner, while successful elytrotomy in early pregnancy has been twice done in New York, once by Harrison, and once by Thomas.

PARALDEHYDE.

DUJARDIN-BEAUMETZ, the eminent therapeutist, has recently (*Bulletin Général de Thérapeutique*, January 30, 1884) examined into the physiological action and therapeutical effects of paraldehyde. This investigation included comparative observations with other known hypnotics and anodynes. All the patients taking paraldehyde found it much less disagreeable than chloral. In ten to fifteen minutes after administration, some subjects, especially females, experience a transient dizziness, which is succeeded by a calm, refreshing sleep, lasting from twelve to eighteen hours. No heaviness or headache is felt on awakening; but, when a full dose is taken, the perspiration exhales a strong odor of aldehyde. As a hypnotic, merely, paraldehyde is superior to chloral and opium, but it does not possess the power to relieve pain. In a case of hepatic colic it afforded no relief. It is in insomnia without pain that its utility is undeniable. It has been found to act happily in the insomnia of the morphiomaniac, and in cases of simple wakefulness unattended with pain. These results accord with the observations made in Philadelphia, with which our readers are familiar.

Dujardin-Beaumetz concludes that we have in paraldehyde a useful addition to our therapeutic resources.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, March 11, 1884.

THE PRESIDENT, R. F. WEIR, M.D., IN THE CHAIR.

SPECIFIC MYOSITIS OF THE GASTROCNEMIUS.

DR. F. LANGE presented a patient whom he first saw about three weeks ago. At that time there was a tumor in the calf of the left leg. The difference in the circumference between the two calves was at the lower part four and four-fifths inches, while at the tuberosity of the tibia it was about two inches. Some of the symptoms led Dr. Lange to assume that it might be of specific nature; he treated the patient accordingly, and the tumor had diminished considerably in size. He intended to present the patient later in order to see whether the result of treatment will be as he expected. He regarded it as specific myositis of the gastrocnemius, extending as high up as the upper attachment of the internal belly of this muscle, so that it could be traced into the popliteal space behind the hamstring muscles. The initial lesion occurred fifteen years ago. No secondary symptoms followed, but later, the patient suffered from a rheumatic affection, located particularly in the clavicles and sternum. These so-called rheumatic attacks were repeated often, but were always treated successfully by the internal administration of iodine. There had never been any affection of the throat or mucous membranes. For a number of years a stricture has existed, which Dr. Lange had located in the prostatic urethra, and it was yielding to the use of bougies. There was also sclerotic thickening of the skin of the pubis, with central depression and peripheral infiltration. The inguinal and other glands, especially the cubital, were enlarged. There was also a deep depression of the skin of the affected calf, but there had not been any ulceration, as the patient said. Dr. Lange thought that probably there had been a subcutaneous gumma which had undergone softening, with subsequent subcutaneous cicatrization. The scar was pigmented, and presented the characteristic appearance of a specific scar. The patient himself traces the origin of the tumor to a small round nodule, which could be felt beneath the skin five years ago in the neighborhood of the scar, and gradually increased in size. Treatment had been energetic, and consisted of daily inunctions of sixty grains of mercury, and at the same time the patient had taken iodide of potassium and mercury internally, according to Ricord's formula. Since about seventeen days, the tumor had been diminishing in size, and was considerably smaller than when the patient first came under observation. At that time the calf was monstrously enlarged and somewhat œdematous; at its lower portion there existed slight redness of the skin with elevation of temperature. While it could be made out clearly that the tumor belonged to the muscular substance of the gastrocnemius, especially in its inner portion, there was still present a diffuse thickening of the surrounding parts, which made a thorough distinct palpation of the boundaries of the tumor impossible. The circumference of the calf has already decreased by two inches in the lower part, and one inch in the upper, corresponding to the tuberosity of the tibia. The tumor itself can be traced more distinctly as a lengthy, hard mass, which is divided into two portions by a slight depression. This relation could only be made out a number of days ago. At no time had there existed any considerable functional disturbance.

He had also seen a gummatous tumor as large as a goose-egg, which occupied the tendon of the biceps femoris, and under specific treatment disappeared entirely.

THE PRESIDENT said that he had seen a similar infiltration in the sterno-cleido-mastoid, and also in the coraco-brachialis muscle, but not of equal size. He asked Dr. Lange if any of the methods by which he determined the location of the stricture in the prostatic portion of the urethra embraced the passage of a full-sized sound to the point of obstruction, with a coincident rectal examination to determine whether the obstruction was in the prostatic urethra. It was the great rarity of the occurrence of stricture in this portion of the urethra that led him to ask these questions.

DR. LANGE said that he had not resorted to the method last mentioned by the President, but that he located the stricture by simply introducing a bougie, which passed in readily up to the point of obstruction, the latter being located so far behind that it must be in the immediate vicinity of the neck of the bladder. The patient, for a number of years, had noticed a diminution in the size of the stream, which within the last few months had been reduced nearly to a dribble.

DR. W. T. BULL presented a case of

RUPTURE OF THE TENDON OF THE QUADRICEPS FEMORIS,

which had been treated by Dr. C. A. Jersey. The man was injured, on Nov. 22, 1883, by having his leg forcibly flexed; he was seen within ten minutes after the injury was sustained, and a dressing of cotton, with a posterior splint, was applied to leg. Twelve hours later this dressing was removed; there was slight swelling around the knee-joint, the anterior surface of the thigh was ecchymotic almost to the groin, and there existed a well-marked depression about two inches above the knee—probably three inches in width. The power of extending the leg was lost. Three long strips of adhesive plaster were passed around the thigh at different points in a figure-of-8 form, making traction in the direction of the knee, approximating the torn edges of the tendon. A Canton-flannel roller was applied from toes to groin, and a plaster splint from ankle over all. The thigh was held at almost a right angle to the body during the application of the entire dressing. The leg was left in this appliance for forty days; after the third week the patient was permitted to go about on crutches. At the end of forty days, the splint having become somewhat softened, a new one was applied, the adhesive-plaster strips and Canton-flannel roller not being disturbed. This second splint was left on for twenty-one days, the patient during the last week being permitted to walk about without crutches. At the expiration of this time the entire dressing was removed. A posterior felt splint, with a bandage from the toes, was worn for one week; then a rubber bandage was applied, which the patient has worn up to the present time. Patient has used a cane until about the tenth of February.

Now—three and a half months from the receipt of the injury—the man has a very useful limb, flexion at the knee being possible to three-quarters its normal extent, and extension perfect and strong. There is much thickening of tissue about the seat of injury, but no sign of the defect beneath the skin usually seen after the rupture of the belly of a muscle.

He had seen several cases of this injury, and in but one was there finally any power of extension whatever, and that was a case in which it existed six months after the injury, and only the fibres of the rectus were torn. As a rule, in an injury of this description the patient loses the power of extension, and he had been led to regard it as a far worse injury, as far as the functions of the knee-joint are concerned, than fracture of the patella. He knew of two persons in whom rupture occurred upon both sides, and both had since been obliged to wear artificial support to enable them to walk.

DR. C. T. POORE had had a case in which rupture occurred on the right side, and there was separation to the extent of about four inches. The patient recovered, and is now able to walk without artificial support, has no limp, and can bend his leg, the only apparent defect being that the extensor muscle is not quite as strong as the other. He treated it by the use of a plaster-of-Paris splint, with a strip of adhesive plaster over the course of the muscle, to hold it down at the point of rupture. There were ultimately about three inches of new tendon formed.

THE PRESIDENT had met with five cases of this injury within two years. In only one was the rupture complete, and he was inclined to believe that in the majority of cases the injury was confined to the central tendon, and that in such cases we had a much better prognosis. In the one torn completely across, which was only seen several years after the accident, there was little or no difficulty in the patient's walking, and no posterior splint was required. All the other cases were treated by the approximation of the divided ends of the muscle by means of strips of adhesive plaster over the thigh anteriorly and fastened below to the sides of the leg, and the use of plaster-of-Paris bandage. He had at present a patient, whom he hoped to show at the next meeting of the Society, in whom both quadriceps tendons had been torn across at the same time, and in whom recovery was nearly complete. In all his cases the injury was the result of muscular force.

DR. JAMES L. LITTLE then read a paper on the

TREATMENT OF FRACTURES OF THE PATELLA BY THE PLASTER-OF-PARIS SPLINT.

(See page 353.)

THE PRESIDENT asked, in presenting the above paper for discussion, what experience, if any, had been obtained by the members of the Society in the treatment of recent fractures of the patella from aspirating the joint for blood effused within it, which had been said to be one of the causes of separation of the fragments. Mr. Heath, of London, and other surgeons had spoken of this method as being serviceable. In the recent discussions which had taken place in Great Britain, arising from Sir Joseph Lister's notable paper on fracture of the patella, the point was made that one of the reasons why bony union did not take place in fracture of the patella was that little fragments of fibrous tissue were caught between the ends of the broken bone. McEwen, of Glasgow, also alludes to this fact, having proved it in one or two dissections. If aspiration allows the fragments to be apposed, it would seem to be sound surgical practice, before applying a splint, to get rid of this interposing small amount of fibrous tissue, by bringing the fragments together and rubbing their surfaces strongly over each other for a few moments.

DR. SANDS doubted whether, in average cases of fracture of the patella, marked superiority could be claimed for any single method of treatment—all methods being more or less imperfect. The treatment recommended by Dr. Little resembled very closely the common one, which consists in placing the limb upon a straight posterior wooden splint, and applying straps of adhesive plaster obliquely above and below the fragments.

He had for many years believed that the extent of primary separation of the fragments depended mainly on two causes, namely, laceration of the fibrous tissues and distention of the knee-joint with blood or inflammatory effusions. He deprecated the premature and forcible attempts often made to approximate the fragments while the joint was distended, believing that such treatment was liable to increase their separation by causing further effusion. He quite agreed with Dr. Little in recommending that, until the subsidence of the swelling, treatment should be restricted to rest of the limb in an extended position, the use of some evaporating lotion, and, when necessary, moderate pressure by means of a flannel or elastic bandage.

He remembered having read many years ago of cases treated in St. Bartholomew's Hospital by simply placing the limb at rest in a straight position upon a posterior splint, approximation of the fragments occurred spontaneously, when the swelling subsided, and very good results were obtained. The uniting medium, although ligamentous, being generally very short, it seemed to him that by the method recommended by Dr. Little, although good results would often be obtained, there might sometimes be found a liability to a tilting of the fragments. Dr. Sands had endeavored to obviate this difficulty by resorting to a method practised by many surgeons, in which strips of moleskin adhesive plaster, attached to the limb above and below the seat of fracture, are brought together and fastened by a buckle directly over the broken bone. Of course, it was presumed that when Dr. Little spoke of approximating the fragments, he meant an approximation of the upper to the lower fragment, as no amount of force was capable of stretching the ligamentum patellæ.

Dr. Sands had also, in some cases, resorted with advantage to Malgaigne's hooks, the points of which were prevented from puncturing the skin by the interposition of several layers of thick adhesive plaster. This practice, he believed, originated with the late Mr. Spence.

He was a little doubtful whether, in bad cases of fracture of the patella, attended with great separation of the fragments, any treatment would produce good results short of a surgical operation. He was convinced, however, that in a majority of cases, many forms of apparatus can be used which would enable the patient to obtain a useful limb.

DR. W. T. BULL said, with regard to the plaster-of-Paris bandage, as distinguished from the plaster-of-Paris splint

in the treatment of this fracture, that he thought Dr. Little had expressed himself adversely to the plaster-of-Paris bandage a little too strongly. It had certainly been thoroughly tested in New York hospitals, and was now generally used in a number of institutions, and he thought the results obtained did not justify the expression that it may justly be condemned.

With regard to this application in the treatment of fracture of the patella, it was the only apparatus which he had used; he regarded it as the simplest form of apparatus that will keep the knee absolutely still, and one which is more easily applied than the apparatus described by Dr. Little. Before applying the plaster bandage he always drew the upper fragment down as far as possible with the hand, and held it there by means of a single strip of adhesive plaster, while a second strip served to "steady" the lower fragment. He had met with a good many cases of fracture of the patella during the last six or seven years, and he had yet to see one in which the upper fragment could not be approximated to within one-fourth to one inch of the lower fragment within a certain time. He said a certain time, because this period varied a great deal according to the quantity of effusion into the joint. He had seen two cases in which the upper fragment could be drawn down directly, and there the plaster splint was applied within a few minutes and allowed to remain until the bone had united by ligament. He had not seen any cases in which the union was entitled to be considered as bony union.

It was suggested, some years ago, that the removal of the effusion could be accelerated by aspiration, and Schede suggested puncturing, washing out the joint, and then treating the puncture with antiseptic dressing. Dr. Bull had not had any experience with the latter method, but he had tried aspiration in two cases. In both he aspirated the joint twice, because the first operation did not facilitate approximation of the fragments, although a small quantity of bloody serum was withdrawn. The second aspiration was about as futile as the first. He had about reached the conclusion that the best method is to allow the effusion to subside, aiding absorption only by firm compression, such as can be made by a firmly applied cotton dressing over the entire limb (laid on a Volkmann's splint), and he had resorted to that measure in cases in which there was a good deal of effusion, and at the end of a period varying from five to ten days, the upper fragment had been approximated within one-quarter to one inch of the lower one with great facility. With such a ligament, if not stretched by flexing the joint too early, the joint functions would be satisfactory.

It seemed to him that no one who had had experience in the use of the apparatus recommended in Dr. Hamilton's *Surgery*, could wish to use it a second time, because it requires constant attention, and the bandages must be renewed every day, or, at furthest, every second or third day. While he believed the apparatus described by Dr. Little is certainly safer for surgeons not experienced in the use of plaster of Paris in the shape of a bandage, he thought the plaster bandage safe enough for any man who has had reasonable experience in the application of bandages in general to the extremities.

DR. F. LANGE had observed a number of cases in which separation of the fragments existed years after injury, varying from one and a half to two and a half inches, and in which the limbs were entirely useful, and the power of extension complete, the patients being able to go up and down stairs without the slightest discomfort. He had treated a number of such cases, and among them were two in which fracture of the patella took place several times, besides one in which separation of the tendon of the quadriceps took place, and in which a gap exists now sufficiently large to allow of the interposing of the hand, yet without functional disturbance of the leg. It seemed to him that after a time the lateral part of the capsular ligaments took up the function of the muscle to a certain extent.

DR. GEORGE A. PETERS had seen one case of fracture of the patella with separation of the fragments to the extent of two inches, and the patient had perfect use of the limb, and was even able to skate.

DR. BULL said that Dr. Little had justly impressed the fact that bony union is not necessary for a useful limb, a fact frequently overlooked by those who have advocated wiring of the patella. He knew of one policeman and one fireman who at the present time are on active duty, and who had ligamentous union of a fractured patella. In one case the ligament was about an eighth of an inch long at the first, but it gradually lengthened until the fragments were separated to the distance of one inch, and yet the man was not aware of the fact.

DR. C. T. POORE asked, if the question of ability to walk was not one of ability of the patient to use the muscle attached to the ruptured tendon. He thought the disability consisted not so much in the separation of the fragments as in the weakness of the muscle which was attached to the upper fragment, and that the difficulty in walking was due to the impossibility for the patient to get accustomed to use the shortened muscle.

DR. LITTLE said that the lower strip of plaster in his apparatus was simply to steady the lower fragment while the upper fragment could be brought into close approximation.

With regard to the difficulty in walking with a long ligamentous union, he thought a distinction should be made between the power of extending the leg and the ability to walk. Patients with a long ligament uniting the fragments are often unable to make complete extension of the limb, but they are able to walk without difficulty. In a recent case in which he applied the splint, at the Post-graduate School, Dr. Powell, who had the case in charge, assured him that he found the patient the day after the accident walking about his room with the aid of a cane. About a year ago, Dr. Stimson presented a case before this Society, in which the patient had had each patella torn from its ligament, and no union had taken place. This man could not extend his legs, but was able to walk about with but little difficulty.

Another point of interest in connection with fractures of this bone, is the liability of the opposite patella to suffer from a similar injury. He had seen a number of cases of this kind. In all these the fractures were caused by muscular action. This is generally attributed to greater strain upon the sound bone and the greater liability of the patient to fall. In two cases which came under his notice, the patients told him that they had suffered a certain amount of pain in each patella before the fracture took place. He had never seen a case in which the fracture was caused by direct violence, that

afterwards suffered from a fracture of the other patella. It is possible that the true explanation of these cases is, that they are caused by an abnormal condition of the bone at the time of fracture. The slight amount of force which caused the fracture in both of these cases, and the pain in the bone felt before the occurrence of the injury, would seem to point in that direction.

Dr. Bull asked Dr. Little with regard to passive motion and the advisability of resorting to it, as mentioned in his paper.

Dr. Little said that he simply quoted Dr. Hamilton.

Dr. Bull said that he had always felt that it was not the right thing to do to resort to passive motion. One should always aim to obtain a short and very strong ligament, and he had always abstained from allowing the patient to move the knee-joint for at least ten or twelve weeks, and by the end of the eighteenth or twentieth week the movements had been satisfactory, and the joint had been strong.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 20, 1884.

The President, Fordyce Barker, M.D., LL.D., in the Chair.

Dr. Leonard Weber read a paper on

LOCOMOTOR ATAXIA AND SYPHILIS.

He commenced by saying that although pathologists had not yet succeeded in establishing the existence of such a thing as syphilitic sclerosis of the posterior columns of the spinal cord, there was a considerable amount of clinical evidence in support of a possible connection between the two affections. In former years it had been customary to omit any investigation of the cord as a seat of syphilitic disease, and it had been only within the last thirty years that there had been a change in this respect. In 1876 Fournier published his first communication upon locomotor ataxia as connected with syphilis, and in it he recognized three types of tabes: first, the lumbar, which was exclusively spinal; second, the cephalic type, in which the cerebral nerves were also affected; and, third, the ophthalmic, or amaurotic, type. The subject had also received the attention of a number of other authors, among which were mentioned Hammond and Hutchinson, and within the last four or five years it had been investigated with much interest by German writers. In 1878 Berger's article was published, and in 1879 Erb's first paper, in which he gave the statistics of one hundred cases. Just before the appearance of the latter, Dr. Weber had had the opportunity of talking with its author upon the subject, and it was in consequence of the interest excited in his mind by this conversation that he had written up the cases of locomotor ataxia occurring in his practice during the last twenty years.

Though his statistics were very remarkable, Erb's views were not received with great favor at the International Medical Congress at London in 1881. At an assembly of neurologists last year at Baden Baden, he had reported a second series of one hundred cases of locomotor ataxia, and in no less than ninety-one of them the patients had had chancre and syphilis, while in only nine was this not the case. On the other hand, in twelve hundred patients over the age of twenty-five, who suffered from nervous diseases other than ataxia, only twenty-two and a half per cent. had had syphilis; and, consequently, he was led to announce the proposition that tabes was probably a syphilitic affection, the development and area of which were determined by special causes. In this paper he stated that tabetic women were frequently syphilitic. Among those who distinctly denied the syphilitic origin of ataxia, Dr. Weber mentioned Moxon, Lancereaux, Westphal, and Rosenthal. They claimed that no causative relation had been proved to exist between syphilis and tabes, and that the prognosis, notwithstanding the most active specific treatment, was no better in cases of tabes in which the patients were syphilitic than in those who were free from any such taint.

Finally, in this connection, Dr. Weber alluded to the paper read before the American Neurological Association, in June, 1883, by Dr. Birdsall, of New York, in which forty-two cases of ataxia were reported, with a percentage of nine and a half patients presenting a history of syphilis. In looking at the statistics of this subject then, he said, one could not but be surprised at the vast discrepancy between different authors; the percentage of cases of tabes with a syphilitic history ranging all the way from one to ninety-one per cent. It was reasonable to assume, however, that it was not until recently that much attention had been given to the investigation of disease of the spinal cord in connection with syphilis. In paralytic dementia, some authors gave as high a percentage as sixty-five of cases in which the patients had had syphilis. Sigmund, after reviewing the cases of syphilis which had come under his care between the years 1849 and 1876, came to the conclusion that the disease (syphilis) was on the increase, both relatively and absolutely, and made the assertion that, on account of its multiform character, the gravity of its lesions, and the likelihood of its transmission to posterity, it was the worst affection that cursed humanity. In this opinion Dr. Weber said he could not but concur.

After speaking of masturbation—in females as well as in males—as a predisposing cause, especially in individuals of a neurotic temperament, not only to functional, but to organic disease of the nervous centres, and stating that in a few of his cases of locomotor ataxia it seemed undoubtedly to be the primary cause, he urged the importance in all cases of initial tabes of resorting to thorough antisyphilitic treatment, to exclude specific disease, if possible. In the cases of syphilis in his own practice during the past twenty years, he had not met with very many instances of disease of the nervous system. Some of the cases of locomotor ataxia which he had seen, it was true, presented a syphilitic history; but syphilis did not seem to him to bear the same direct causative relation to the disease that rheumatic trouble did. In tabes, in general, there was often a great difference in the symptoms in different cases, and it was difficult to ascertain the exact seat of the disease, since the neighboring parts, as well as the posterior columns of the cord, were liable to be affected. This was especially true of syphilitic tabes. At the last meeting of the American Neurological Association, Dr. Mills, of Philadelphia, had asserted that sclerosis of the posterior columns of the cord was probably of lepto-meningeal origin. The disease was protean in its pathological and

clinical manifestations, but three principal forms were recognized: first, the typical, as first described by Duchenne; second, the form in which the symptoms were less severe, and might be mistaken for functional derangement but for their persistence; and, third, the atypical, with which syphilis was most frequently associated. No typical case of ataxia had ever yet been proved to be of syphilitic origin, or had yet been cured by antisyphilitic treatment.

As to the diagnosis, the symptoms of specific and non-specific tabes were, for the most part, the same; and as to the prognosis, this was relatively favorable when the syphilitic trouble had not been of long duration, and when the symptoms were irregular in character, and yielded to specific treatment. In regard to the treatment, he could only say that the results had by no means proved equal to what had been anticipated by the advocates of the syphilitic origin of tabes. Still, in a certain proportion of cases, a fair amount of benefit had been derived from it, and the treatment that he advised was thorough inunction with unguentum hydrargyri, and the free use of baths and the iodide of potassium. During the last ten years, his own results had been better than in the ten years preceding, and he attributed this to the fact that ten years ago he gave up the use of the protoiodide of mercury and other preparations of the drug given internally, and since then had almost exclusively employed inunction, in the manner advised by Sigmund. He was confident that anyone who could try this plan thoroughly, would secure quicker, better, and more permanent cures in syphilis in general than by the internal administration of mercury. Occasionally a patient was met with in whose case inunction could not be practised; but such instances were rare. In sudden and alarming manifestations occurring in old syphilitic cases, the iodide of potassium, pushed to the limit of tolerance, afforded better results than any other measure.

Dr. Weber then gave some statistics taken from his own private practice. Of one hundred and thirty-four patients suffering from syphilis, one hundred and fifteen were males and nineteen females, and none were under observation for less than four years; the most of them from ten to twenty years. He gave the history of one of these cases, as it was of interest as being the only instance which had come under his notice in which acute syphilis occurred twice. At the time of the first attack, he placed himself under Dr. Weber's care, and, under the effect of treatment, the disease became latent within two years. He then had no further trouble for three years, when, five years after contracting syphilis the first time, he again had a venereal sore, which was followed by all the signs of acute syphilis, the attack being precisely similar in almost every respect to the first one which he had had. Within two years, the disease became latent; but from 1872 to 1876 he suffered more or less from neuralgic attacks. Of the one hundred and thirty-four cases of syphilis, there were eighteen, or thirteen and a half per cent., in which the disease attacked the central nervous system. In eight patients, six of whom were males and two females, the brain alone was affected; in five (all males) the brain and spinal cord together; and in five, four of whom were males and one female, the cord alone. Of the first eight, two had died of cerebral syphilis, and six were still alive, but not cured. Of the five in whom both the brain and cord were implicated, two had died and three survived; and of the five in whom the disease was confined to the cord, one (the woman) had died of syphilitic hemiplegia, and the other four were still alive.

Of locomotor ataxia, he had the records of seventeen cases. Out of the seventeen cases, three of the patients, or eighteen and a half per cent., were syphilitic. In one the syphilis was contracted after the tabes had existed for a number of years; but in the other two cases it seemed to constitute an important etiological factor. From his study of the subject he had arrived at the following conclusions:

1. There was not sufficient evidence to show that syphilis was the direct cause of locomotor ataxia.

2. There was plenty of proof that syphilis attacked the spinal cord as well as the brain and meninges, and that the disease might sometimes be followed by tabes.

3. Syphilis of the nervous centres occurred sooner in those not treated than in those subjected to a proper course of treatment.

4. Syphilitic nervous lesions were seldom, if ever, cured. Therefore, in order to prevent their occurrence, if possible, early and long-continued treatment of constitutional syphilis should be insisted on.

5. Mercurial inunction, properly carried out, constituted the best means at our disposal for reducing the disease to early and harmless latency.

The President remarked that in Dr. Weber's cases of ataxia with syphilitic history, the efficacy of specific treatment had not been specially emphasized, and said that he should like to present the history of three cases of his own, in which the therapeutic results were quite marked.

The first was that of a gentleman thirty-five years old, whom he was called to attend in 1875. He had severe pains in the knees and ankle-joints, walked with difficulty, and believed himself to be suffering from rheumatism. He rapidly grew worse, however, until complete paraplegia set in. There was total loss of sensation in both lower extremities, with paralysis of the rectum and bladder; but no mental impairment. Although he confessed that he had been frequently exposed to the danger of contracting syphilis, he denied ever having had a sore on the penis, but stated that he had sometimes noticed a little eruption on his skin and had had sore throat. Under the circumstances, Dr. Barker thought it well to try the effect of specific treatment, and prescribed fifteen grains of iodide of potassium, with one-sixteenth of a grain of corrosive sublimate, three times a day. Soon after, Dr. James R. Wood was called in consultation, and he expressed the opinion that the case was hopeless, but advised no change in treatment. The iodide was then increased to forty grains (no change being made in the dose of the bichloride), and in the course of two months the patient gradually recovered control of the lower extremities, while the paralysis of the bladder and rectum disappeared. He also regained his flesh, which, before, he had been rapidly losing. The treatment was kept up, with the addition of the use of galvanism, and two years afterward he was married. He remained in excellent health until about six weeks ago, when he began to suffer again from pains in his lower extremities. A few days since he was attacked by bronchitis, which was

attended by an amount of prostration altogether disproportionate to the disease; but under the use of doses of fifteen grains of iodide of potassium and ten grains of muriate of ammonia, he was now doing well.

The second case was that of a gentleman, fifty-five years of age, who complained of great difficulty in walking. He had been under the care of a well-known homœopathic practitioner, but on hearing of the result in the above case, had called in Dr. Barker. In 1844, he said, he had had syphilis in Paris, and had been treated by Ricord. He was placed on the same mixed treatment as the other patient, was considerably benefited, and had continued in comparatively good health. The treatment was still resumed at intervals. The third case was that of a physician who had been a surgeon in the Confederate Army, and who consulted Dr. Barker two years ago. His health had been gradually failing for one or two years, there being dulness of intellect, indistinct articulation and difficulty in using the limbs. Syphilis was suspected, although he denied ever having had the disease, and he was placed on fifteen grains of iodide of potassium with one thirty-second of a grain of corrosive sublimate, three times a day. After a fortnight Dr. Clymer was called in consultation; at that time he had paralysis of one side; but within a month the improvement was so rapid that both Dr. Clymer and himself regarded it as something marvellous. He had continued to do well up to the present time. Dr. Barker said that he had mentioned these instances simply for the purpose of illustrating one point, and that was the possibility of getting light in regard to the pathology in certain cases by the effect of therapeutic measures.

Dr. Amidon said that he desired to put himself on record as strongly opposed to the proposition to call typical locomotor ataxia a syphilitic disease. In the series of cases reported in Dr. Birdsall's paper, to which reference had been made by Dr. Weber, only nine and a half patients presented a syphilitic history. The connection between syphilis and ataxia, which certain authorities had endeavored to establish, was based entirely on statistical data; but the unreliability of such a basis was seen in the vast difference of results among the various writers who had compiled statistics on the subject. Our author, as he had been surprised to learn to-night, had put the proportion of tabetic cases with a history of syphilis as one per cent., while Erb in his last hundred cases had reported it at ninety-one per cent.; statistical inferences, therefore, he thought were utterly worthless. The deduction drawn from the results of treatment pointed distinctly to the fact that ataxia was not a syphilitic disease. A good many cases of ataxia of various forms, it was true, had been relieved or cured by antisyphilitic treatment; but never yet a single one of true sclerosis of the posterior columns. Again, the pathology of the disease showed that it was not syphilitic. If it were, it must necessarily be a tertiary lesion, and the tertiary lesions of syphilis were well recognized as of altogether different character from those met with in the affection under discussion. These were well shown in the liver, for instance, in which, whether there was originally a gummatous deposit or cirrhosis, the liver tissue finally became destroyed in the parts affected, and deep cicatricial depressions resulted, which were localized and well defined. The course of the disease also furnished an argument against its syphilitic origin. True progressive locomotor ataxia, as its name indicated, was very slow in its development; while the manifestations of tertiary syphilis were likely to appear suddenly, and rapidly increase in severity. The weight of evidence, he thought, therefore, was decidedly against the lesions of locomotor ataxia being a syphilitic lesion.

Dr. R. W. Taylor stated that he had already placed himself on record, in the work in which he had been a collaborator with the late Prof. Bumstead, as an opponent of this theory, based simply on statistics of the causation of locomotor ataxia by syphilis. He was, consequently, very glad to see the cautious manner in which Dr. Weber had dealt with the subject. The syphilitic etiology of the disease had been first hinted at by Duchenne, but simply as the result of the fact that he had noticed a coincidence of the two affections in certain instances. He found, however, that antisyphilitic treatment had no effect on locomotor ataxia, and from his study of the subject was led to the conclusion that there was in reality no connection between the two. Until Fournier's publication the profession had looked upon sexual excess, alcoholism, gout, rheumatism, cold, etc., as the primary causes of tabes; but Fournier was struck by the fact, as was indeed very natural, that out of thirty cases of ataxia which came under his observation, twenty-four of them were in syphilitic subjects, and it seemed evident to him that from such a large proportion of syphilitic subjects, syphilis must have a direct causative relation to ataxia. The grounds on which Fournier based the connection between the two diseases were as follows:

1. Frequency of association (as seen in Fournier's cases).

2. The occurrence of ataxia in the tertiary period (by which was understood the third year).

3. Identity of symptoms. (The ataxic symptoms which syphilis produced, however, Dr. Taylor held, differed widely from those seen in true locomotor ataxia.)

4. The benefit derived from antisyphilitic treatment. (In this Fournier stood almost alone.)

5. The symmetry of the lesions. (Syphilitic lesions, on the contrary, were, as a rule, asymmetrical.)

6. No other cause could be assigned for the disease.

Fournier, in his last work, had reported 94 syphilitic cases out of 103 of ataxia; Erb, in his first hundred cases, 61 per cent.; Vulpian 15 out of 126; and Rosenthal 1 out of 65. Here was certainly sufficient disparity to cause doubt in regard to the matter.

There were two other points which could throw more light on the subject, viz., pathology and therapeutics. In the pathological anatomy of syphilis of the nervous system there are found: (1) affections of the vessels; (2) hyperæmia; (3) connective tissue infiltration; (4) gummatous infiltration. These lesions were perfectly well understood. In this distribution it was known that syphilis did not invade a system; its manifestations being in patches, or at random, as it were. The lesions were likely to be of meningeal origin, and scattered more or less asymmetrically. Westphal and Gowers had made autopsies in those dying from ataxia in syphilitic and non-syphilitic subjects, and found precisely the same lesions in both. Erb said very ingeniously that syphilis might produce "a neuropathic state," in which lesions of the nervous system were apt to occur. This expression, however, was a very vague and indefinite one.

In the statistics reported it was painful to read some of the details of the cases (which are for the most part retrospective), given as conclusive evidence of the patients having had syphilis, and the histories were frequently not methodically and critically examined. Yet he (Dr. Taylor) had been called to task by at least one critic in this city for his abrupt statement in the work before referred to, that there was no proof, other than that furnished by statistics, of the syphilitic origin of ataxia, and that the pathological features of the two affections are entirely different.

Dr. Birdsall said that he came in too late to hear the greater part of Dr. Weber's paper, but he heartily agreed with him in his conclusions, particularly the first and second. The statistics which he had reported in his own paper before the American Neurological Association, he had collected to add to those already recorded in Europe, and he believed that they were the first that had been made in the United States up to that time. Of the forty-two cases of locomotor ataxia given, four were in syphilitic subjects, or nine and a half per cent. Most of these had been under his personal observation, and at the Department for Nervous Diseases in the Manhattan Eye and Ear Hospital the work of carefully recording such cases, and noting the presence or absence of syphilis had been begun long before Erb published his first series of cases. It was a matter of surprise to him that his statistics varied so greatly from those of Erb, though they were not so widely different from those of some other writers. Rosenthal had reported one hundred and five cases, with twelve per cent. syphilitic; Bernhardt thirty-seven, with twenty-five per cent. syphilitic; Westphal seventy-five, with thirty-three per cent. syphilitic; and Gowers thirty-three, with thirty-seven per cent. syphilitic. In Erb's first hundred cases, as had been previously mentioned, eighty-eight per cent. of the patients had had syphilis; and, in his second hundred, no less than ninety-one per cent. Without counting Erb's last hundred cases, the number now reported in all amounted to five hundred and twenty-five, with an average of forty-three per cent. in syphilitic subjects. It was not proper, however, to come to any positive conclusion from such a small number of cases.

He could not agree with the other speakers that statistics ought to be ignored altogether; and yet he thought that inferences derived from them ought to be received with caution. In preparing his own cases for publication, in order to eliminate the possibility of the report being affected by any personal bias, he had submitted the records to the inspection of a gentleman who was not specially interested in the subject, and did not know for what purpose the cases were being collated, with the request that he would go over them carefully and note the various points involved. His conclusions were identical with those at which he had previously arrived. On account of the meagre number of cases, however, he did not regard them as of any special value; and the same was true, he thought, of Erb's series of cases, with their extraordinarily large percentage of syphilitic subjects. Furthermore, in regard to Erb's cases, it might perhaps not be known that this authority did not make any distinction between chancre and chancroid, which would render a modification of the conclusions reached by him necessary in the eyes of all dualists. Still, if it was proved that syphilis was associated more often with ataxia than other nervous disorders, the idea of some connection between the two affections ought not to be ignored entirely. At the same time, he felt positive that up to the present time no convincing proof had been adduced of such a connection; since syphilis was characterized by particular lesions which we know pretty well, and which were quite different from those belonging to progressive locomotor ataxia. Another point—in Erb's cases, as a rule, the syphilis had occurred a long time before the tabetic symptoms appeared, sometimes ten or twenty years. It had been pointed out that in syphilis of the cord, secondary lesions sometimes still remained after gummata and similar troubles had disappeared. Later, it might be that we should have to recognize syphilis, like sexual excess, as one of the predisposing causes which rendered the system liable to suffer from sclerosis of the posterior columns of the cord. In the consideration of this whole question it was important to separate sclerosis of the posterior columns from other troubles, since affections of the lateral columns and other adjacent parts might give rise to symptoms resembling true locomotor ataxia.

Dr. Edward L. Keyes thought that in the discussion the history, literature, and statistical aspect of ataxia had been sufficiently considered, and said that he would content himself with a few remarks derived from his own experience. In observations upon tabetic patients with syphilis, however, the statistical element could not altogether be done away with. He did not believe that pure sclerosis of the posterior columns was directly caused by syphilis; but, at the same time, he could not see why ataxia might not result indirectly from the effects of that disease on the system. In the course of his practice, he had been called upon to treat a number of ataxic patients which he could not now state positively, but which were certainly not less than two or three dozen. There was one case which he recalled particularly, in which there was a gummatous tumor of the cord, with paraplegia, wasting of the muscles of both lower extremities, and paralysis of the bladder. He became entirely well, so far as muscular weakness was concerned, but was left with all the symptoms of locomotor ataxia, which treatment entirely failed to do away with. The case terminated fatally. At present he had under his care a young gentleman who had had the ordinary manifestations of syphilis, followed by cerebral symptoms. These disappeared under treatment; but now he had commencing locomotor ataxia, for which he could assign no other cause than the syphilis. He had placed him upon pretty active treatment, but did not as yet know what would be the result. He was inclined, therefore, to attach some weight to syphilis as an active factor in the production of ataxic symptoms. Again, he had known of one or two instances in which ataxic symptoms had been distinctly relieved by antisyphilitic treatment. The means upon which he relied were large doses of iodide of potassium and mercurial inunction. It was his practice to commence with the iodide and push it to the point of tolerance. When it produced a depressing effect upon the system he remitted it, and placed the patient on tonic treatment for a time; after which he commenced the mercurial inunction, in connection with hot baths, as was done at the Hot Springs. One case that he particularly had in mind had markedly

improved under this course, though it had not been cured, and he was therefore convinced of the efficacy of specific treatment in certain cases with ataxic symptoms.

Dr. A. McLane Hamilton stated that he fully concurred in the opinions expressed by Drs. Birdsall, Taylor, Amidon, and Weber. He thought that the great trouble in this whole matter was that two totally distinct affections had been confounded with each other, viz., classic sclerosis of the posterior columns of the cord (true progressive locomotor ataxia) and cerebro-spinal syphilis. He had found that not more than twelve per cent. of patients affected with true locomotor ataxia had had syphilis; while among the irregular cases of ataxia this was true of a very much larger proportion. In this class of cases, he found enormous doses of iodide of potassium (200 or 300 grains), given in a mild alkaline water, efficient.

Dr. F. N. Otis said that he thought we could hardly afford to disregard altogether the experience of men of such eminent reputation in their special fields as Erb and Fournier, however much we might be inclined to reject statistics, as a rule. These were the two observers with the largest experience, and who had devoted the most study to this subject, considered in its twofold aspect, and we should, therefore, hesitate long before disallowing the evidence which they produced. His own experience, he said, had been small; but his knowledge of the characteristics of syphilis led him to believe that it could invade a system. If locomotor ataxia were a disease of the connective tissue, it acted in the same way as syphilis. Dr. Otis illustrated his point by a reference to the pathology of syphilitic disease of the testicle. Here there was a deposit of gummy material, so-called, which did not in reality differ at all from ordinary germinal matter, and which was capable of forming cicatricial tissue. If the affection were actively treated, the exudation might be taken up; but, if it were let alone, the mass of the testicle would become irregular in outline by the contraction of the fibrous bands formed, and these bands would continue to increase, and strangulate the tissue of the organ. After this cicatricial material began to deposit, no treatment would affect it very much, though a small portion of the testicle might perhaps be saved. In syphilis of the liver, too, there was a very remarkable development throughout of cicatricial material. It had been stated by good authorities that these lines of cicatrization followed the lymph distribution, though this had been doubted a few years ago, because in certain of the tissues, as the bones, for instance, the presence of lymphatic vessels had not then been demonstrated. As before remarked, in cases in which this cicatricial tissue had been laid down there was very little hope of accomplishing anything in the way of its removal by treatment.

Dr. Otis then went on to say that in locomotor ataxia we are ignorant of the pathological significance of the lesions found, and quoted Erb's conclusions as to the limited extent of the knowledge as yet possessed on the subject. Since the true character of the pathological process is still unknown, then, he continued, it would not perhaps be amiss to think of ataxia in connection with such a disease as syphilis, which certainly showed something of the same character in its manifestations. By many it is not regarded as a syphilitic disease because it is not affected by antisyphilitic treatment, but, as was seen in the glance which had been taken at the pathology of this disease in general, when syphilis itself reached the cicatricial stage, no benefit is to be derived from treatment. If it could be demonstrated that there were lymphatic vessels distributed through the cord, by means of which this cicatricial formation might be induced, there would be no longer any difficulty, he thought, in claiming that locomotor ataxia might be distinctly caused by syphilis.

His own personal experience, as he had intimated, is insignificant; but it might, perhaps, be of interest to relate one case that he had met with. Three years ago a gentleman had consulted him who was suffering from tabes, as it seemed to him, and this opinion was confirmed by an eminent neurologist of this city, who pronounced it a typical case of sclerosis of the posterior columns. Already he had a great deal of bladder trouble in addition to the difficulty in locomotion, and the prognosis was regarded as very unfavorable. The treatment recommended was the systematic administration of ergot, carried to as high a point as possible. Afterwards it occurred to him that the bladder trouble might perhaps be aggravated by something located about the genito-urinary apparatus, and on examination he found a contracted meatus. As the want of control of the bladder was the symptom which was the most distressing to the patient, and, indeed, made him continually unhappy, he did not hesitate thoroughly to divide the meatus, in the hope that it might perhaps have some effect, at least, in relieving this, and in the course of a week, much to his gratification, he found that the trouble had so diminished that he now had to use only one towel where eight had been required before. The ergot was continued steadily for two months, during which the urinary trouble continued to improve, but as at the end of this it began to be very badly borne, and as in the meanwhile Dr. Otis had seen the report of the researches of Erb in regard to ataxia, he determined to place the patient on the use of mercury and iodide of potassium. There was no history of syphilis, but he said he had once had a sore on his penis. When he got up to seventy drops of the saturated solution of iodide of potassium, he immediately began to improve. At the present time he is entirely free from the bladder trouble, and is much improved in his gait. In relating this case Dr. Otis said that he had not lost sight of the fact that ataxia not infrequently has its periods of quiescence and of advance. He has had three cases altogether, in which considerable benefit was apparently derived from the kind of treatment mentioned, and in two of them he found that all the urinary trouble was not dependent on the tabes.

As a result of his experience and study, therefore, he felt satisfied that no case of ataxia, if seen at a reasonably early period, should be allowed to go on without the trial of a thorough course of mercury and iodide of potassium, both drugs being carried up to the point of tolerance. In an experience of thirty years he had never yet seen a single case materially damaged by such treatment. The patient suffering from tabes was certainly entitled to the benefit of the doubt as long as there was any question about the true pathology of the disease.

Dr. Spitzka thought that the question was looked at from too narrow a point of view. One important fact all agree to, viz., that in secondary syphilis the disease

undoubtedly affects the cerebro-spinal axis. It has been shown that sometimes in secondary syphilis there is absolute loss of tendon reflex. Why, then, should this not occur in tertiary syphilis? Syphilitic meningitis does not differ at all, in his opinion, from ordinary syphilis. In the position that he had taken, Erb only expressed an extreme view in regard to what is undoubtedly true in the majority of cases. In his own experience he has found that two-thirds of his tabetic patients were syphilitics. In his female cases, however, there was no history of syphilis, but they were only three in number. The disease was apparently ascribable in one case to an attack of scarlatina, occurring after the patient had reached adult life, and in the others to cold. Statistics, as a rule, will show that, in syphilitics, ataxia occurs more frequently than almost any other affection of the nervous system. The proportion of cases in syphilitics, however, is very much the same as of cases of general paralysis of the insane. This disease has been more fully studied on account of the facilities afforded by asylums, and it has been found that the nearer such institutions are to large cities, the greater is the proportion of syphilitics among those suffering from paralytic dementia. In conclusion, Dr. Spitzka denied that tabes was a strictly systemic disease, claiming that the lesions are often found in other parts besides the posterior columns.

NEW INVENTIONS.

ON A NEW FORM OF FORCEPS FOR FACILITATING THE OPERATION OF TRACHELORRHAPHY.

By JOSEPH PRICE, M.D.,
of Philadelphia.

One of the principal difficulties in performing the operation of trachelorrhaphy successfully, is in making a denusion of the cicatricial surfaces which shall be complete and symmetrical, without impairing the integrity of the two strips of membrane which are to form the canal in the new cervix. To facilitate this portion of the operation, I have devised a pair of forceps, with the intention of using them to cover the portion left undenuded, and at the same time support and throw into prominence the portion it is desired to remove.

The forceps resemble a pair of long dressing forceps, provided with a lock of the ordinary pattern. One blade of the forceps is dilated to a flattened spoon shape, designed to fit the external surface of the cervix, whilst the other is gradually tapered so as to form a much longer and narrower blade. Each blade is furnished with a series of small teeth to fix it securely in the cervical tissues (Fig. 1).

Emmet has so fully described the operation that no subsequent author has added anything of importance to it. The operation is substantially the same as that described when using these forceps, and it is consequently unnecessary to go through its various steps. The uterus is brought down by the double wire tractor and held firmly by an assistant. The amount and shape of the denusion having been decided upon, the lips are held open, and the long blade of the forceps introduced as far as the internal os in the median line of the axis of the uterus on the lower half of the split cervix. It now covers the portion of tissue to be left undenuded. The broad blade fits the external surface of the cervix, and the forceps are locked in that position (Fig. 2). With a broad-bladed scalpel introduced flat along the back of the blade of the forceps, it is now easy to cut a thin slice of the torn tissues of one side the size and shape of the portion to be denuded, clear up into the cicatricial wedge at the angle of the tear. Reversing the knife, a similar slice is removed from the other side.

Fig. 1.

Fig. 2.

Fig. 3.

The forceps are now removed from the lower and applied to the upper gaping lip, and two similar sections made from it. The two pair of incisions should meet well back from the angle of the tear, removing as much as possible of the wedge of cicatricial tissue, included within the dotted lines (Fig. 3), since, as has been pointed out by Emmet, to its non-removal are due many failures in this operation. Four clean cuts should be made into the angle, and each pair of these should unite in a horizontal line, at a sharp angle, well back from the surface.

I have described a symmetrical bilateral laceration for the sake of clearness, recognizing that the operation would be modified in each case in actual practice by the seat and extent of the tear. In each case, however, the cervical canal would be left undenuded in precisely a similar manner. By the use of these forceps perfect coaptation of the inner portion of the denusion is a necessity, since a band of precisely similar size and shape is protected on each surface, and accidental clos-

ure of the cervical canal is rendered an impossibility. The operation is more speedy, the coaptation easier, and the resistance afforded by the broad blade fixes, to a certain extent, the yielding tissues under the knife.

In the cases in which they have been used the result has been in every way satisfactory, and I have no hesitation in recommending the plan for a more general trial.

NEWS ITEMS.

MUNICH.

(From our Travelling Correspondent.)

THE PATHOLOGICAL INSTITUTE IN MUNICH can scarcely be said to equal those in the other universities of Germany and Austria. The museum is rich in some things, though poor in others. It contains one preparation which certainly is unique. It is a gigantic skeleton, more than seven and a half feet high, the great peculiarity being that the individual who possessed it was of the usual size until his eighteenth year, when he began to grow, the new growth starting from a hyperostosis of the lower jaw. The bones are simply immense; they are not only very long, but more than relatively thick, and covered with osteophyte formations. It is difficult to place this specimen pathologically, whether to regard it as the result of an affection affecting a single system—here the osseous—or to regard the whole, muscles and all parts together, as a true gigantic growth depending on a congenital disposition.

In malformations the collection is relatively poor, not to be compared in this respect with the museum in Prague, the latter, having probably the richest collection in Europe. From some cause or other, Bohemia seems to produce more malformations than any other country, and here, if I recollect aright, the only successful operation on a twin monster was made. The father, a country physician, operated shortly after birth, one of the children surviving the operation.

THE LABORATORIES OF THE HYGIENIC INSTITUTE are all exceedingly well equipped, and several novel contrivances have been introduced. The director of the Institute is Prof. v. Pettenkofer, whom perhaps most of the readers of THE MEDICAL NEWS will know from the publication, in the *Popular Science Monthly*, four years ago, of translations of some of his unequalled popular lectures. One part of the institution is devoted to investigations carried out for private individuals, which investigations are paid for by the individual. The yearly appropriation for the maintenance of the institution is only eight thousand marks, this, of course, being outside of the pay of the professor and assistants, and with this they accomplish wonders. I should have mentioned that the courses here are also largely attended by architects.

BEER.—One is always astonished in Munich at the immense amount of beer that is drank there, especially when it is considered that the beer is so heavy, containing one per cent. more alcohol than most of the beer elsewhere manufactured in Germany. I doubt if people would be able to drink, with impunity, a similar amount of alcohol in any other form—that of whiskey, for example. Yet we are accustomed to think in America that whiskey is the best, purest, and most healthful form of alcohol. In most parts of Germany the beer drinking is all done at night; beyond a glass at the midday meal, few people think of drinking during the day. From the soporific effects of beer one would think it should only be drank when the labor of the day is over, and one wants to bring himself into a pleasant, sleepy frame of mind before going to bed. In Munich they take it with their breakfast, after their breakfast, and, in fact, at all times, and one cannot help thinking, when he looks upon the stalwart figures, and sees how productive they are, both physically and mentally, "What would these men be if they only drank beer at night?"

TENNESSEE STATE MEDICAL SOCIETY.—The fifty-first annual meeting of this Society will be held on April 8th, at Chattanooga.

THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA will meet in Selma, on April 8th, and will continue four days.

MISSISSIPPI STATE MEDICAL ASSOCIATION.—The annual meeting of this Association will be held at West Point on the 2d, 3d, and 4th of April.

UNIVERSITY OF LOUISVILLE.—The forty-seventh annual commencement of the Medical Department of this institution was held on February 28. The degree of M.D. was conferred on eighty-four graduates.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending March 15, 1884, indicate that rheumatism has considerably increased, and that pneumonia, whooping-cough, inflammation of the kidneys, dysentery, and inflammation of the bowels have increased, and that scarlet fever has decreased in area of prevalence.

Including reports by regular observers and others, diphtheria was reported present during the week ending March 15th, and since, at thirteen places, scarlet fever at eighteen places, and measles at five places. One case of smallpox was reported in Bath, Clinton Co., on March 15th.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 18 TO MARCH 24, 1884.

MATTHEWS, WASHINGTON, *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the Missouri, and to report in person to the Surgeon-General of the Army for duty in his office.—*Par 12, S. O. 62, A. G. O.*, March 15, 1884.

GIBSON, R. J., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Hays, Kansas, and ordered to Fort Wingate, New Mexico, for duty.—*Par. 3, S. O. 58, Headquarters Department of the Missouri*, March 18, 1884.

GANDY, CHARLES M., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Brady, Michigan, as post surgeon. *Par. 6, S. O. 56, Headquarters Department of the East*, March 22, 1884.

CROSBY, WILLIAM D., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Hauchuca, A. T., and ordered to Fort McDonald, A. T., for duty.—*Par. 1, S. O. 20, Headquarters Department of Arizona*, March 15, 1884.

EDIE, GUY L., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort McIntosh, Texas.

ROBERTSON, REUBEN L., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Fort Ringgold, Texas.—*S. O. 33, Par. 3 and 4, Headquarters Department of Texas*, March 17, 2884.

ORIGINAL LECTURES.

ON THE TREATMENT OF TYPHOID FEVER.

A Clinical Lecture.

BY PROF. DUJARDIN-BEAUMETZ,
OF PARIS.

(Concluded from page 353.)

GENTLEMEN: I pass now to the study of germicide medication. You already well know that a great number of antiseptic medicaments have become, by their therapeutic application, antipyretic medicaments; this is what has happened in the case of many substances derived from the aromatic series. It remains for me now to speak of medicaments which, while possessing an evident antiseptic action, have not, at the same time, any effect on the temperature.

It is thus that there have been successively applied to the treatment of typhoid fever, creasote by Pecholier and Morache, iodine and the iodides by Aran, Magonty, and Wilbrand; a combination of iodine and carbolic acid by Roberts Bartholow and James C. Wilson; chlorine and the hypochlorites by Chomel and Beaufort; the sulphites and hyposulphites by Polli; preparations of copper by Burq and Moricourt; mercurial preparations (the black sulphuret) by Serres; and calomel by Wunderlich and Liebermeister, also by Bartholow and Wilson in America. I shall not dwell further on these antiseptic preparations, this medication not being established on a scientific basis; for, if by the introduction of antiseptic substances it has been possible to disinfect the stools, it has been impossible to arrest the course of the disease, that is, to prevent the development and penetration of the micro-organisms into the entire economy.

Calomel, which terminates this long series of antiseptic medicines, belongs rather to the evacuant than to the parasiticide medication, and will serve as a bond of union between the two. The idea which gave rise to the evacuant medication was perfectly just, especially at the time when this medication was first instituted. In fact, we have seen De Larroque maintain since 1832 that it is in the fecal matters that the septic element of the disease is found, and that it is necessary, in order to prevent the poisoning of the entire organism, to eliminate these septic matters by stool. You have seen that experimental physiology has justified this view of the subject; only, in their haste to eliminate the peccant principle, the founders of the evacuant method have gone a little too far, and have not hesitated to give every day an ounce of castor oil or a bottle of Seidlitz water. Carried to this extreme, the purgative method is rather injurious than useful; it weakens the patient, and, by exaggerating the peristaltic movements of the diseased intestine, it may be the exciting cause of hemorrhage or of perforation. Utilized in moderation, however, the evacuant method is a serviceable adjuvant to treatment, promoting elimination of putrescent matters.

It remains for me to speak of the tonic and empirical medication. The tonic medication is now universally popular, and in order to repair the incessant losses which the organism undergoes from the exaggerated combustions which the febrile process determines, preparations of quinine have been employed, and, along with suitable alimentation, alcoholic stimulants.

I shall not repeat what I said about alimentation while on the hygienic treatment of typhoid fever, nor shall I dwell further on preparations of bark, only pointing out this fact, that the potions containing the soft extract of cinchona, which are so much administered in these cases, often pass through the alimentary canal without undergoing any modification; and in many instances I have found in the stools of my patients almost the whole of the extract which I had given them. But I must devote a little more time to a consideration of alcohol.

Since the works of Todd in England, and those of my master, Behier, in France, the use of alcohol in this fever has acquired great vogue, and I have already spoken of the advantages and disadvantages of this medication, while on the treatment of pneumonia. In typhoid fever, alcohol does not act as an antipyretic, and if you wish to lower the temperature by this agent, you will have to give such large quantities of it that the treatment will be more dangerous than useful; but, given in proper doses, alcohol acts as a tonic, and, moreover, diminishes that process of denutrition which results from exaggeration of the combustions; this is its great utility.

To those who adopt the opinions of Lallemand, Perrin, and Duroy, it is very difficult to explain this waste-restraining action, because, in their belief, alcohol does not undergo any transformation in the organism. According to the hypothesis which I have defended, and which seems to-day experimentally demonstrated, this kind of effect is quite readily explicable. I maintain, in fact, that alcohol, in presence of oxyhæmoglobin, and by virtue of the feeble bond which in this substance unites oxygen to hæmoglobin, appropriates the oxygen, and, transforming this oxyhæmoglobin to reduced hæmoglobin, modifies and arrests in a certain measure the oxidation of the tissues of the economy.

Todd, Murchison, Fourrier, and Autellet have shown us the good effects of the alcoholic medication in typhoid fever. Notwithstanding the advantageous results claimed, I do not believe that we ought, following the example of Jaccoud, to give alcohol to all our typhoid patients indiscriminately; and I believe that it is best to reserve this remedial agent for certain cases which I shall soon have occasion to describe.

By the side of alcohol we should place that triatomic alcohol known under the name of glycerine, which Semmola has administered with good effect in fevers, and which you may utilize advantageously

under the form of glycero-tartaric lemonade in your practice.[1]

I shall have finished this long series of medicaments and medications when I have spoken to you of ergot of rye, which is recommended by Duboué. Basing himself on physiological data, very ingenious but rather hypothetical, this authority advances the opinion that the typhoid virus affects particularly the muscular contractility, and especially that of the arterioles, and it is this paralysis of the vaso-motors which constitutes the essence of typhoid fever. To this want of contractility he opposes medicaments which have the property of augmenting the tone of the bloodvessels, and, in particular, ergot of rye. The trials which I have made with this treatment have not given any positive results, and I believe that if the spurred rye and its derivations are ever indicated in this disease, it is to combat the intestinal hemorrhages which so often occur.

In this therapeutic arsenal, the richness of which I have just shown you, physicians have chosen arms of various kinds, sometimes a single weapon, sometimes several, with which to fight abdominal typhus, and have thus constituted single medications and complex medications, and, according as they have applied them exclusively to all cases of dothinenteritis or as they have varied them according to circumstances, they have made thereof exclusive medications, or medications according to the indications. Lastly, another group of physicians have thought that by the unaided efforts of nature, typhoid fever ought to end in recovery, and have applied to the treatment of this disease the doctrine of expectancy. Hence we have these three systems of treatment: exclusive medication, expectancy, and medication according to indications. I cannot too much protest against exclusive medication, whether in typhoid fever or in any other disease. One patient is never just like another patient, and it is absurd to suppose that the practice of medicine can be summed up in a simple breviary, containing on the one hand the description of the disease, and on the other the therapeutic formula that will cure it. Age, sex, state of the vital forces, the symptomatic aggregate, above all the genius of the epidemic, modify the disease in its totality, and at every step in its evolution.

The science of the physician consists in modifying the treatment according to the divers circumstances, and it is from this fact that results that intimate union which I regard as so indispensable, of clinical medicine and therapeutics. Do you believe that in a case of typhoid fever the disease is the same in an infant as in an old person? Do you believe that grave cases can be assimilable to light cases? Do you believe that benign epidemics are suitable for comparison with malignant epidemics? Do you believe, in a word, that one same therapeutic formula, rigorous and uniform, can be made applicable to all cases indiscriminately, and that we can thus reduce to a same level, all forms of the disease?

I know well that the partisans of the exclusive treatment, whether single or complex, pretend to reduce all cases of the disease to one and the same type, but this is only an assumption which is not supported by the facts, and as Professor Vulpian says with so much justice, we have not as yet found a kind of treatment which is sure to modify the march of this disease and arrest its course. There are physicians who pretend to have methods which jugulate typhoid fever; but when we come to examine attentively all these so-called jugulating medications, we perceive that to obtain all the benefits which they promise, they must be applied in the first seven days of the disease, that is to say, in a period in which one is almost sure to confound simple gastro-intestinal irritation (*embarras-gastrique*) with typhoid fever. It is these same physicians who have called to the support of their doctrine of jugulation, the mild forms of typhoid fever described by Jules Guerin, and which the Germans have treated under the name of typhus-levissimus, and in which one sees the malady undergo its evolution in from twelve to fifteen days; but these are natural forms of the disease and not the result of modification by therapeutic means.

There is no such thing in existence as expectancy, properly so-called, applied as a medical or therapeutical system, for physicians who boast of employing this method take all due pains, nevertheless, to surround the patient with all the hygienic care which his situation demands, and to attend to the hygiene of your patient is not to deprive him of therapeutic aid, but to render him excellent therapeutic service. But often these hygienic attentions are insufficient, and more active intervention is required, and you must then resort *secundum artem* to the medication according to indications which I have styled armed expectancy. This expression, *armed expectancy*, has given rise to much criticism. Germain Sée has condemned it as "revolutionary." I do not consider that it has this signification, and if our interference is demanded, it is not to effect any violent changes in the economy, but to calm and regulate the disorders there going on; it is then rather as conservators than as radical innovators that we act.

But, you may ask, what are the rules of this "intervention"? On what manifestations do you depend when you decide on the advisability of more active therapeutic endeavors? These three points should guide you, Gentlemen: the intensity of the fever, the general state of the patient, the complications which arise; and, to set forth with more method these three points, we will in imagination take a case of typhoid fever, and follow it through the various phases of its evolution.

Your first care will be, as soon as you suspect typhoid fever, to surround your patient with all the hygienic precautions which I have above enumerated; you take the temperature twice a day, at precisely eight o'clock in the morning and five in the afternoon. Although the rectal temperature is always preferable to that of the axilla, the latter generally suffices. You watch carefully the abdominal functions, and you regulate the bowels by giving mild laxatives, such as saline purgatives and the natural mineral waters, which are better than castor oil. It will be well to cover the abdomen of your patient with a layer of cotton batting, which is kept applied by means of a body bandage. This application immobilizes, in a certain measure, the intestinal mass, and prevents the too sudden shocks,

[1] Semmola's formula is as follows:

R.—Glycerine, ... 3 parts (by weight).
Tartaric acid, ... 2 " "
Water, ... 500 " " —M.

To be used freely as a beverage.

which, in the present disordered state of the intestines, may do mischief. This wadding is much superior to poultices, which are inconvenient by reason of the clammy and uncomfortable moisture which attends them. Then I make my patient the subject of serious attention, being ready to act according to the rules I have just mentioned; if the temperature does not exceed 102° F.; if no complication arises, I adhere to the hygienic treatment, and those mild laxatives administered every other day, and you have many times seen in my service that these simple means are quite sufficient for benign forms of the disease.

When the temperature exceeds 102° F., I begin the practice of cold lotions (sponging), which I repeat two or three times a day, or even oftener, according to the elevation of the temperature. These means often suffice to keep the temperature in the neighborhood of 102° F. But when it exceeds 103° F., and marches towards 104° F., then is the time for my intervention with salicylic acid. I give at noon, and in the space of an hour, four capsules, each containing seven and a half grains of salicylic acid, and I take care to administer during the day a certain quantity of milk, namely, about a quart.

Under the influence of the salicylic acid there is a depression of temperature; but to render this, in a manner, permanent, I repeat my dose the next day, at the same hour; then I omit this treatment for a day or two, and note the height of the thermal curve. If it attains the previous figure, I again give the acid for two days, in the same dose; and if the temperature still tends to exceed 104° F., I double the dose, and then give sixty grains in two hours—in doses of seven and a half grains every fifteen minutes; and sometimes I go as high as seventy-five grains; but I never prolong beyond two days the action of the medicament. Such are the sole means which I employ against the pyrexia.

In order to judge of the condition of the vital forces, I am guided by the assemblage of symptoms and the state of the pulse. As long as the pulse remains between 80 and 90 a minute, I let the patient alone; when it rises above 90, I give alcohol, either in the form of Todd's mixture, milk punch containing brandy, or Spanish or Sicilian wines.

In the immense majority of cases, when the fever takes on a certain acuteness, there supervenes a nocturnal delirium of mild type; when this delirium becomes more active and boisterous, I resort to chloral, which I much prefer in these cases to opium and its derivations, which, in fact, have for their physiological effect to congest the brain; and you well understand that in ileo-typhus, in which this congestion is the rule, opiates may do harm. I administer, then, hydrate of chloral, in the dose of fifteen to forty-five grains, in a mixture of egg and milk sweetened; and I frequently associate bromide with the chloral.

A boisterous delirium often accompanies ataxic phenomena, constituting thus what was formerly described under the name of ataxo-adynamic fever. When this state is not too intense, and the fever is attended with dryness of the skin, I place my patient in a warm bath, which I repeat every day or two. If the ataxo-adynamic condition becomes more intense, I have recourse to envelopment in the wet sheet, which envelopment I repeat two or three times a day, according to the necessity. I add often in these cases to the chloral or the bromide, preparations of musk, of which Trousseau made great account, and I give from seven and a half to fifteen grains of musk, in pills rather than in potion, the latter being very disagreeable to the taste. Such are the therapeutic means which I employ in the adynamic and ataxic forms of typhoid fever, and I come now to other morbid determinations of the disease.

The pulmonary complications are the most frequent. They include bronchitis, pneumonia, broncho-pneumonia, and sometimes, though very rarely, pleurisy. In the treatment of these pulmonary complications, you should avoid the application of blisters; the patient, in fact, being in a state of constant agitation in his bed, and the functions of the skin being altered, these fly-blisters are attended with ulceration, or even gangrene, and may thus become a serious evil. You should use, instead, dry cups, which render us great service in typhoid fever with pulmonary congestion, and with these cups you may cover the whole chest of your patient. You may also give internally a little tincture of aconite, which diminishes, though feebly, this congestive tendency. It will be well also to have your patients well propped up in their beds, so as to prevent those hypostatic congestions which too horizontal a position determines.

I have but little to say about the cardiac complications, at least from the point of view of treatment. Here we have, unhappily, one of the causes of sudden death in typhoid fever, not easily explicable always, whether we suppose, as Dieulafoy does, a simple reflex action, whether we attribute the fatality, as does Hayem, to symptomatic myositis, or whether we make it depend, according to Laveran and Bussard, on cerebral anæmia, or whether it results from these last two causes combined, as Huchard maintains. Our therapeutics, in fact, have very little power to prevent such a termination. I agree, at the same time, with Huchard, that tonics, general stimulants, and perhaps nitrite of amyl, may in these cases render some little service.

On the part of the digestive tube there may supervene several complications. One of these consists in the appearance of gastric troubles, and I have already spoken to you of them while on the subject of diet in this disease; the other is an accident much graver and always mortal, namely, perforation of the bowels; lastly, the third results from the occurrence of intestinal hemorrhages. I have little to say to you from a therapeutic point of view concerning intestinal perforations, yet apart from perforations as a determining cause, peritonitis has been sometimes observed in typhoid patients. In these cases there is a possibility of a recovery by a rigorous treatment, which consists in the application of ice to the abdomen, and immobilization of the intestinal mass. As for intestinal hemorrhages, we have seen that when they are of moderate intensity they are often rather beneficial than otherwise; unhappily it often occurs that they are too abundant, and we are called upon to interfere with applications of ice to the abdomen, and the internal administration of perchloride of iron or ergotine. For my part I very much prefer ergotine or ergotinine, which I give in hypodermic injections. I have thus far omitted to say anything about the diarrhœa. While recognizing the fact that a typhoid patient ought to have two or three movements a day,

there are cases when the passages are altogether too frequent, and exhaust the patient. I advise you in these cases to make use of the salicylate of bismuth, in doses of from forty to sixty grains a day.

The renal complications present a certain gravity in typhoid fever. Fothergill even thinks that it is the non-elimination of the products of combustion which is the point of departure of the typhoid state. The kidney, in fact, is congested in typhoid fever, and the urine is albuminous. Whether we are concerned with an infectious nephritis, as Bouchard thinks, or with a congestive nephritis, there none the less results a perturbation in the functions of the renal organ, and I have already spoken to you of the important part which I assign to this perturbation in explaining the toxic action of certain medicaments in typhoid patients. It is necessary, then, to favor the functions of urination, and you can accomplish this by giving abundant drinks to your patients, and one of the best is certainly milk. I share, in this regard, the view of Jaccoud, who thinks it a good thing to give to his fever patients one or two quarts of milk a day.

The skin, as you know, may become the seat of mortifications more or less deep (bed-sores); these eschars are sometimes of great gravity, extending so far as to expose the bones of the pelvis. I have even observed myelitis consecutive to the opening of the vertebral canal in typhoid patients. I have already shown you by what hygienic means you may avert these mortifications of the skin, but when despite your care they appear, you will require a special dressing for them. The best in my opinion is a solution of chloral. It was in a case of gangrenous ulceration of the hip of great extent, in a young typhoid female, that I made the first local application of chloral, and the astonishing results which I obtained from this outward medication encouraged me to study and make known the antiseptic properties of chloral, and this work of mine has served as a basis for the local therapeutic employ of chloral, to-day so much in vogue.

You make, with one per cent. solutions of chloral, frequently repeated dressings, and you have care especially to introduce into the excavation which results from the mortification of the tissues, wadding or lint soaked in this solution.

Apart from these eschars I ought to mention erysipelas of an infectious kind, and for that very reason of extraordinary gravity; phlegmons, accidents quite common in typhoid fever of a subinflammatory character, deeply hidden in the interstices of the tissues, and the possibility of which ought to make you examine, with the most scrupulous attention, the painful points of which typhoid patients sometimes complain during their convalescence. You well understand that these purulent collections should be thoroughly drained and treated by antiseptic washings and injections.

Such are, Gentlemen, the principal complications which you will have to meet; there are still others of which I shall not speak, for they are exceptional; such as gangrene of the limbs, œdema of the glottis resulting from laryngo-typhus, suppurative parotitis, but it is very rarely that you will have occasion to treat these complications.

I shall say but little of the convalescence of typhoid fever; remarking at the same time that relapses are frequent in this disease, and especially that variety of remittent or intermittent fever which accompanies convalescence from typhoid fever; a variety which David Borelli has plausibly explained by the presence of intestinal ulcerations slow to cicatrize. The entire therapeutics of convalescence is summed up in a problem of alimentation, and you should employ all your care and skill in directing aright the diet.

Such is the aggregate of therapeutic means which you ought to employ in typhoid fever; in putting them in practice you will succeed in curing the great majority of your cases, and without admitting with certain physicians that it is possible, by therapeutic means, to cause the mortality of typhoid fever to disappear, I am of the opinion that there is no disease in which the successes won by therapeutics are more numerous.

It is in following step by step the disease whose evolution he has mastered, that the physician by his earnest and thoughtful care and his attention to little points, by his energetic intervention when complications appear, may in many cases say that he has saved the life of his patient, and to express briefly my thought, I might conclude with this phrase, which, although a solecism, is the truth—"The best treatment of typhoid fever is a good physician."

ORIGINAL ARTICLES.

TWO CASES OF RUPTURE OF THE UTERUS;

AND SOME REFLECTIONS UPON THE ABUSE OF ERGOT IN OBSTETRIC PRACTICE.

BY GEORGE J. ENGELMANN, M.D.,
OF ST LOUIS, MO

RUPTURE of the uterus—one of the most fatal, but fortunately also one of the most rare, of all the dangerous accidents attending parturition—is so seldom met with that every well-observed case should be put upon record. This occurrence, fatal in almost every instance (in at least ninety-five per cent. of the cases recorded), is only too often due to a want of vigilance, to tardy interference, sometimes to ill-timed and ill-advised interference, on the part of the accoucheur. In many regions of England and the continent of Europe, where pelvic deformities abound, rupture of the uterus may result from these causes—healthy labor pains, a healthy child, and a narrow outlet; sometimes the uterine tissue is lacerated by pressure of the contracting muscle against bony projections of a diseased pelvis. In this country, however, especially in the Western States, I may almost say throughout the entire land, with the exception of those great cities which are centres of poverty and misery, as well as of wealth and luxury, a deformed pelvis is almost unknown to the obstetrician. But, unfortunately, where by a healthy development of the female frame we are freed from the main cause of this terrible dystocia, a cause sufficient for its occurrence is offered by the physician himself, and the most frequent source of uterine rupture can safely be said to lie in meddlesome midwifery of the worst kind—in the abuse of ergot.

Much is said in condemnation of meddlesome

midwifery as applied to early operative interference, to version, or to the use of the obstetric forceps; but meddlesome midwifery of a far more dangerous kind, because less evident and more common, has to a great extent escaped criticism; this is the liberal use of ergot in obstetric practice. What the forceps are to the skilled obstetrician, ergot is to the unthinking practitioner and the midwife. Aye, more, it supplies the place of every other remedy—of patience as well as the skilled hand. Ergot, I regret to say, seems to be the all-powerful and the only agent in use in the obstetric practice of but too many; and so much more injury than good is done by this drug, so potent for good or evil, that I would condemn its use in obstetric practice altogether. Parturient women would be better off if ergot was stricken from the pharmacopœia: it is never necessary, and where really needed cannot be relied upon for immediate action, so that other means must be resorted to. It does good service in its proper place, if given after the contents of the uterus have been expelled—to prevent hemorrhage, and to stimulate contraction when labor is completed, especially after the physician has left his patient. Where really needed, in cases of hemorrhage, in which the uterine fibres refuse to act, the drug cannot be relied upon; the stomach, in that enfeebled condition of the system, refuses to absorb it, and, if absorbed, its action is slow and insufficient. We must use more effective means. Hence, in extreme cases, in which uterine contractions are demanded, it is useless; and in cases in which it does answer the desired purpose, we have a choice of other means more satisfactory, and less injurious. A vast deal of injury to women in labor would be avoided—in confinement at term as well as in abortion—were this dangerous drug ostracized.

None will deny that in extreme cases—in cases of post-partum hemorrhage, for instance—more energetic means for stimulating uterine contractions are demanded; and even in milder cases we also have less harmful and more effective means. If we are doubtful of sufficient uterine contraction after the expulsion of the placenta, friction or kneading of the fundus, quinine, or injections of hot carbolized water—vaginal or uterine—will by far better answer the purpose. A vaginal injection of hot carbolized water after expulsion of the placenta is stimulating, cleansing, and advantageous in many ways. Like ergot, it hastens the contraction, and, beyond that, cleanses and lessens the danger of infection. During labor, ergot should rarely be used; for safety's sake, I should say, never. Although the injury done by the drug is not often severe—it maims oftener than it kills—it is all the worse for its frequency, and, not being so palpable, has escaped notice and condemnation to a great extent. The use of this drug during labor is a widespread evil; the authorities always call attention to ergot as a powerful oxytocic, and, though they limit its use, do not sufficiently warn us of the terrible dangers which accompany it, and the practitioner is more or less given the impression that it—ergot—is the most necessary aid to the accoucheur: this illusion must be dispelled, and I will here show how serious may be the evil consequences of giving the drug during labor.[1] The authorities claim that in by far the greater number of cases of rupture of the uterus, the cause may be sought in the use or abuse of ergot; and in order to demonstrate clearly the injurious effect of that drug, I shall relate the two that have come under my own observation.

Although each possesses features of interest in itself, I look upon these terrible cases of death of mother and child, the sudden taking away of strong, healthy women in the midst of the parturient process, as the most striking demonstration possible of the dangerous abuse of ergot.

Case I.—A healthy negro woman, some twenty-six years of age, who had borne two children at term without unusual suffering was about being confined with her third; the waters had broken and labor was progressing, but apparently not to the full satisfaction of the impatient attendant, whether physician or midwife I do not recollect, and ergot was given. The pains came more rapidly and with increasing severity; and, as the story of those present is, the patient, in the agonies of intense labor-pains, suddenly cried out, suffering from a pain more severe than any preceding; she fell back, apparently in great distress, labor-pains completely ceased, and she sank rapidly with great suffering. The attendant having left, a physician was sent for, who found the patient in a state of collapse, death soon following.

It was my good fortune, by the kind permission of the Coroner, Dr. Auler, to make the post-mortem examination. The abdomen being opened, I found the fœtus involved in large masses of clotted blood in the lower left portion of the abdominal cavity; the uterus was flabby, partially contracted, containing the somewhat adherent placenta and large clots of blood. The laceration extended from the central portion of the cervical juncture, perhaps a little to the left, through the lateral portion of the body into the upper third. The pelvis was normal, with the exception of a bony protuberance near the ischio-pubic juncture upon the brim; but whether the rupture was in any way furthered by pressure of the tense muscles against this exostosis, I am unwilling to say. The child was of moderate size, if anything, below the average; the os was partially dilated, yielding readily. To my mind, the fatal result must mainly, if not altogether, be ascribed to the hyperactivity of the muscles, over-stimulated by ergot.

Case II. was that of a lady, aged twenty-five, married four years, with a fine frame and an un-

[1] I have been of late so thoroughly impressed with the necessity of limiting the prevalent use of ergot, on account of the many resulting evils, to which my attention was first directed by these fatal cases, that I was induced to read a paper upon the use and abuse of ergot at the late meeting of the American Gynecological Society. Being in hopes that if other—more effective and harmless—means for stimulating uterine contractions were more generally introduced, ergot would be more readily given up than by merely pointing out the dangers of its use, I have supplemented this by a paper read before the St. Louis Obstetrical and Gynecological Society, on the use of external manipulation in obstetric practice; for it is mainly by the proper *management* of labor—by *patience*, by *posture* of the patient, and by *external manipulation*, that we can safely accomplish what ergot was *supposed* to accomplish in labor.

usually healthy, vigorous constitution. She was delivered three years ago of her first child in a normal labor with good getting up, and passed through her pregnancy without unusual symptoms, being in the best of health. Uterine pain began during the day; at 10 P.M. the midwife arrived, the pains continuing with moderate regularity. She remained during the night, but left on the following morning, returning toward evening. The pains continued with increasing severity, the midwife remaining throughout the night and also upon the following day, the third; as the labor seemed to be unnecessarily delayed, under favorable circumstances, with the patient in excellent condition, a physician was sent for, who arrived at 6 P.M. He pronounced her condition good, and at once ordered ergot. He informs me that he found the os dilated, but the parts rigid and dry, and that the arm came down at half-past nine. The ergot arrived at 7 P.M. One drachm was given, and in thirty minutes a second; a few minutes later a third (soon after giving this third dose the attending physician upon examination informed the friends that the child was not in the right position, that an arm was presenting). Having placed the patient under chloroform at 10 P.M., he attempted an interference, but failing, sent for a consultant, who was unable to accomplish more, though desisting only after persistent efforts continued during the space of an hour. A second consultant was then sent for, as the case appeared a desperate one. Arriving at 2 A.M. on the morning of the fourth day, he, too, attempted to turn the unusually large child in the now firmly contracted uterus, but with no more success than his predecessors. After the previous attendants had again attempted to interfere, but with no better success, the patient was left at three o'clock in the morning, with instructions to refill the bottle of ergot and continue its use, as the labor-pains seemed to have ceased. Between two and three o'clock she suddenly felt a sharp pain, and cried out with suffering, complaining at the same time of the excessive motion of the child; after this, however, all was quiet; the physicians had left with instructions to continue the medicine, and neither labor-pains nor motion of the child was again felt, the patient remaining very quiet for the balance of the night.

I was summoned on the morning of the fourth day, in great haste, with a request to "bring my instruments to cut up a child as it couldn't be delivered," and reached the patient at 10 A.M. I found her a healthy, strong, young woman, partially sitting up in bed, semirecumbent, supported by both arms, apparently none the worse for all she had undergone during the three days of this protracted labor. The peculiar position, and the anxious care with which she seemed to preserve it, guarding herself against even the slightest change, struck me at once. Equally remarkable was the shape of the abdomen, which was peculiar, presenting a well-defined prominence, bulging out directly beneath the rib under the region of the heart in the left side. Her pulse was excellent, quite strong, and regular. The lucid statement of the attending physician, who had arrived at the same time, the history briefly gathered, her excellent condition, the immense discolored arm which hung limp in the vagina—all led me to infer that it was merely a question of turning an unusually large child, and I expected nothing worse. Heeding but little the peculiar prominent mass in the epigastrium, I was simply puzzled by the distinctness with which she made the statement that early in the morning, at 2.30 A.M., the child gave a sudden jump, which made her cry out with pain and say that she wished that it would not move so violently, whilst the discolored arm seemed to point to the death of the fœtus at a much earlier period.

Although every movement caused her great pain and could be accomplished but slowly, I at once placed the patient in the proper position, in the dorsal decubitus, upon the edge of the bed. Her pulse, which had become somewhat rapid under the excitement, soon recovered, when the chloroform had taken effect. I found a third shoulder presentation; the right arm in the vagina, the parts excessively dry and tense, the uterus spasmodically contracted and not in the least relaxed by the chloroform, so that it was with difficulty that I could move my hand in the cavity. The child was of enormous size, my hand would not pass beyond the abdomen, nor was I enabled to move any of the parts in the least. The conditions did not seem improved after disarticulation of the presenting arm. The attending physician introduced his hand, after mine became completely tired out, with no better result; after another effort I was enabled to bring down what I supposed by its size to be a leg, but found it to be the left arm, which I also disarticulated. Still unable to accomplish more, I attempted eventration, gaining but little on account of the tetanic contraction of the parts. I was greatly puzzled at not being able to find any portion of the lower extremities, which in this position should have been in front quite near the os; as far as I was able to move my hand within the rigidly contracted uterus I could find nothing but the monstrous body of the child, and began to suppose some deformity of the fœtus, until I was enabled to reach the hips, but these were closely constricted by a ring of uterine tissue. I now suspected the true condition of affairs—a rupture of the uterus, the hips within the opening, the breach forming the bulging prominence within the abdominal cavity directly beneath the ribs.

Seeing no relaxation of the tissue, I informed the relatives of the condition of affairs and the urgency of decisive interference. Consent was at once given to any measures that might appear necessary, and although having only my pocket-case at hand, I made the necessary preparations to open the abdominal cavity and extract the child. Before, however, taking this step, which seemed a hazardous one with this slender apparatus, especially without properly prepared sponges, I determined to make one more effort at version, and succeeded in passing my hand along the hips of the child, through the constricting ring into the abdominal cavity, and was enabled to seize one foot, which I found directly beneath the diaphragm. Version and extraction

were rapidly accomplished, the attending physician greatly aiding by grasping and following down the uterine fundus; with the assistance of friction and cold water the womb fairly contracted, and I at once delivered the placenta, and then mopped the uterine cavity, first with hot water, and then with perchloride of iron. There was no loss of blood, and the uterus contracted into a firm and hard, although very large, globe. Child and placenta were both of enormous size, and in beginning decomposition. The patient was brought to bed; brandy was given by subcutaneous injection; the pulse, which had become very rapid and feeble toward the last, seemed to revive a little, and she recovered consciousness. Not a drop of blood was lost; the uterus remained contracted in a firm, hard, and enormously large globe. But notwithstanding the apparently favorable conditions, the pulse became very rapid and feeble, the patient sank, and died quietly within two hours after delivery.

In considering these cases, it will be seen that the first is a typical example of rupture of the uterus; the patient being seized suddenly with an intense pain, the symptoms of internal hemorrhage, shock, and collapse following; the child expelled into the uterine cavity involved in the clots consequent upon internal hemorrhage.

The second, however, is remarkable in so far that the rupture, which was well characterized, did not result in any such consequences for the time being. The patient lived ten hours after the occurrence of the rupture, and the fœtus, at least so far as the presenting parts were concerned, did not change position. The pulse gave no indication of shock or hemorrhage, nor was any hemorrhage visible. This peculiar condition is readily explained by the unusual size of the child: the huge trunk remained within the uterus, the head upon the right ilium, the breach beneath the diaphragm and abdominal wall in the abdominal cavity, so that this immense mass was firmly wedged in and tightly held within the firm contractions of an unusually powerful uterine muscle, which, in the lacerated portion, seemed to encircle the breech of the child as with a band of steel. The laceration was in the upper third of the left side toward the fundus. Another striking feature, to me at least, was the firm and permanent contraction, both before and after expulsion; the free use of ergot might have produced the former, hot water and perchloride of iron the latter.

Whatever of interest these two cases may have as cases of rupture of the uterus, both seem to me a terrible warning of the dangers of ergot in obstetric practice. In the first case nature, and if not nature, certainly the obstetric forceps, would readily have completed delivery without the slightest difficulty, had the uterus not been over-stimulated by the dangerous drug. In the second, delivery was impossible by the forces of nature, and the powerful muscle of an unusually strong body was driven to enormous exertions, until it grasped in tetanic contraction the immense mass of the unusually large ovum, preventing any rectification of position, and, unable to expel the mass by its proper outlet, it gave way in the effort.

One word with regard to the final management of these cases. Notwithstanding the absence of all symptoms of hemorrhage, and the apparently perfect contraction of the uterus, a certain amount of blood and amniotic fluid must have escaped into the abdominal cavity, and, as a rule, a large quantity accumulates there, hence it is best to remove this; whether the child be delivered per vaginam or by abdominal section, the opening of the abdomen affords the patient a better chance of recovery, as hemorrhage can then be stopped, the lacerated surfaces of the uterine muscle properly united, and, above all, the abdominal cavity cleansed. This treatment was not here resorted to because the necessary apparatus was not at hand, not even within reach, and the patient was rapidly sinking from the shock received.

Of the lesser and more frequent evils which result from the use of ergot we hear but little, yet they are many; extreme cases, fortunately, are rare, but, not being reported, possibly are more frequent than is generally supposed.

Of all the milder, more harmless, and yet effective stimulants to uterine contraction, I would, if a medicine is to be given, mainly urge quinine, which is always a valuable aid to the parturient process in this climate; for the purpose of altering painful and ineffective labor-pains we have in opium and ipecac, especially in Dover's powders, a by far better and more natural means than in ergot; and for the purpose of furthering post-partum contractions, the one legitimate use of ergot to which I would see it limited, massage of the uterus and hot-water vaginal injections are equally effective, more rapid, and preferable; the douche, when combined with carbolic acid, permanganate of potash, or other disinfectants, guards us at the same time from an even far greater danger. These means are always on hand, and why should we not resort to them in ordinary cases?

When necessity urges, as in case of post-partum hemorrhage, ergot certainly is useless, even dangerous, and cannot be relied upon: the stomach may not assimilate it, and, even should it do so, the action is slow, and only subcutaneous injections may be of use, whilst intrauterine injections of hot carbolized water, external manipulation, massage, or astringents—vinegar, alum, and above all perchloride of iron—within the uterine cavity, act immediately and effectively; friction of the surface, massage, and the hot vaginal douche will serve well before delivery is completed. Later, after expulsion of the ovum, and if more vigorous measures are necessary, we can rely upon intrauterine injections and the use of astringents within the cavity.

306 Locust Street, St. Louis.

THE TREATMENT OF TYPHOID FEVER.

By GEORGE L. PEABODY, M.D.,

visiting physician to bellevue hospital, pathologist to the new york hospital, etc.

(Concluded from page 360.)

The introduction of the antipyretic use of cold water has been traced by Lauder Brunton to the time of Augustus, whose life Musa saved by its

means. The systematic application of cold affusions to the body to reduce the temperature of fever patients, together with accurate thermometric investigations, seems to have been first practised by John Currie in 1797. This method seems to have been much resorted to in the first half of the present century in England, Egypt, Russia, and Germany, but it seems to have subsequently disappeared from therapeutic procedures, and to have been again revived by Dr. Brand,[1] of Stettin. He has applied this treatment to a large number of cases, and has collected statistics of eight thousand cases thus treated; and he counts among his followers Liebermeister, Bartels, Immermann, Niemeyer, Ziemssen, Jurgensen, and many others.

During the twenty years 1848–67, 2228 cases of typhoid fever were admitted into the Charité in Berlin; of these 405 died, which was a rate of mortality of 18 per cent. The antipyretic treatment was then introduced, and during the nine years 1868–76, 2086 cases were admitted, and 267 died, giving a mortality rate of 13 per cent. We are told that of these cases 64 were admitted in a condition not admitting of the treatment, and that if they be deducted from the list, the mortality would be only 10.5 per cent. In the Prussian army, during the seven years from 1868–74, the rate of mortality from typhoid fever was 15 per cent. The antipyretic treatment, chiefly in the form of cold bathing, was then introduced, and during the next seven years the mortality rate fell to 9.7 per cent.

At the meeting of the Academy of the Sciences in Paris on February 26, 1883, Dumontpallier finished a contribution to the study of the subject of refrigeration of the human body in fevers, especially in typhoid fever, with these among his conclusions: "That the treatment by refrigeration in typhoid fever judiciously conducted affords great advantages in the therapeutics of that disease. One cannot pretend to cure all patients, but I have the firm conviction that in thus modifying the high temperature this method can lessen the mortality to a very considerable extent."

During the year 1883 this subject was very frequently under discussion in the Academy of Medicine in Paris. Much of the discussion has been interesting and instructive, and much discursive and personal; and it may be supposed that the method by cold baths, being a German method, has not been adopted with alacrity by the French. On the 15th of March, 1883, Ricklin gave statistics of results in German hospitals by this method, which serve to justify our faith in it, when we consider that they have been subjected to a rigid scrutiny by "the hereditary enemy." According to this writer, in the Bethanie Hospital, in Berlin, during the fourteen years from 1868 to 1881, 3140 cases were treated, with a mortality between 13 and 14 per cent. In the hospital in Munich, from 1868 to 1875, Ziemssen treated 2223 cases, with a mortality of 205, or 9.2 per cent.; and Zaubzer, with 206 cases, lost only 8.8 per cent. These two observers treated their patients systematically with cold baths.

Jaccoud, at a session of the Academy on February 6, 1883, recounted his method of treating this disease, which consists in the administration of from 30 to 80 grammes of alcohol a day in teaspoonful doses, with 3 or 4 grammes of extract of cinchona, and, in addition to this, sponge baths of vinegar or aromatic vinegar and water four, six, eight, or ten times a day, in accordance with the temperature. In certain cases in which this treatment fails to reduce the temperature, he gives from 1.5 to 2 grammes of bromohydrate of quinine or salicylic acid every other day. He thinks he has thus produced an amelioration of nearly all the graver symptoms of the disease. During the past sixteen years he has treated 655 patients after this manner, with a mortality of 10.83 per cent. He has collected 80,140 cases, treated on the expectant plan, with a mortality of 19.23 per cent.

Dr. Frantz Glénard, writing last year in the *Gaz. hebd. de Méd. et de Chir.*, and also in the *Lyon Méd.*, gives briefly the results obtained in Germany and in Lyons by the method of Brand. His conclusions were adopted almost unanimously by the hospital physicians of Lyons—twenty-two out of twenty-four being in their favor.

They are briefly recapitulated thus:

The method of treatment which exercises the most favorable influence over the progress and termination of typhoid fever is that which has for its foundation refrigeration by cold water and continual feeding of the patient from the beginning to the end of the disease. The therapeutic procedure which responds best to the former of these indications is the use of repeated cold full baths, with cold compresses in the intervals between the baths.

Typhoid fever treated methodically, and from a period soon after its commencement, assumes an encouraging character during its entire course, and the duration of convalescence is considerably shortened. Complications are rare under these conditions, and there are no grave consequences, either immediate or remote, which can be directly imputed to this method. If one begins this treatment after the disease is under full headway, instead of at its commencement, so that the endeavor is made rather to combat complications than to prevent them, the results, though not so marked as if the method were early adopted, are still better than those given by any other mode of therapeutics.

Consequently, the physicians of the hospitals of Lyons declare themselves partisans of Brand's method of the treatment of typhoid fever, with the conviction that this method regularly applied, especially from the beginning of the disease, has considerably lessened the percentage of mortality.

Glénard then goes on to quote statistics from the German army with which we are already familiar, and to place side by side the statistics of results obtained in the German army, on the one hand, and in the French army on the other, and to draw from this comparison a new argument in favor of cold baths. "We have," he writes, "as a means of drawing conclusions in regard to this method, the

[1] Not having had access to Brand's book I have been obliged to accept statistics and other matters derived originally from him, as they appear in Cayley's lectures and in the writings of others.

results of twenty years in Germany, and of ten years in the hospitals of Lyons. Since its adoption the mortality in both has fallen from 26 per cent. to 9 per cent.; and in some of the German hospitals, and in private practice in Stettin and Lyons, it has fallen to 1 or 2 per cent.

"One is justified in saying," he continues, "that the rate of mortality in typhoid fever treated by cold baths depends upon the strictness with which the method is applied, and that it can consequently be indefinitely reduced.

"Under the expectant method the mortality depends solely upon the severity of the epidemic; it depends upon the disease, and not upon the doctor."

This sanction of the German method, almost unanimously adopted by hospital physicians of so large, and wealthy, and intelligent a city as Lyons, and that, too, under the well-recognized circumstances of existing antipathy to things German on the part of the French, is certainly sincere, and should command our earnest attention.

I do not wish to be understood to imply that all the writers in current medical literature are in favor of Brand's method; but I do believe that a careful comparison of them all will lead an unbiased reader to believe that the most exact and careful observers are, as a rule, strongly in its favor.

In the hospital at Basle, where a mortality of 27.3 per cent. occurred in 1718 cases treated on the expectant plan, in 1483 cases treated on the antipyretic system they had a mortality of 8.8 per cent.

In the hospital at Kiel, 330 patients treated on the expectant plan gave a mortality of 15.4 per cent.; 160 cases treated by Jurgensen on the antipyretic plan gave a mortality of 5.1 per cent.

In the Military Hospital of Stettin, 1591 cases treated on the expectant plan gave a mortality of 25.6 per cent; of 121 cases treated in the same hospital antipyretically, all recovered except 5, giving thus a mortality of about 4 per cent.

The general results, as given by Dr. Brand, show that of 8141 cases treated antipyretically, 600 have died, giving thus a mortality of 7.4 per cent. To crown all, Dr. Brand has treated 211 successive cases in private practice without a single death and without the occurrence of peritonitis or perforation. Let us remember that these were not selected cases, but that they occurred consecutively in the practice of a single individual.

After comparing these results with those that I have already given, can anyone doubt the efficacy of cold water in the treatment of this disease? In time of peace, during the year following the civil war in this country, 1285 cases of typhoid fever occurred in our army, with 635 deaths, showing a mortality of something over 49 per cent. It seems to me that we should no longer hesitate to adopt this treatment as a routine method of combating the most dangerous symptom of this grave disease.

It is not generally adopted in this country, or even in this city, and I fear its general use will be long postponed, notwithstanding all these facts. The community is prejudiced against it, and we doctors have first to undertake the task of educating the community to its use. How often have I heard doctors condemn it as an unsafe and violent procedure, who had never once seen it systematically tried. Like tracheotomy, it is mildly suggested by a timid doctor, as a possibility of saving a moribund patient, and, like tracheotomy, failing to restore life to a dead man, it has fallen into disrepute. How many hospitals in this city are properly equipped with portable bath-tubs that can be of service for this purpose, and how many hospital physicians among us have seen systematically made use of them?

Cold water is variously applied: in the cold bath, cold affusion, cold pack, cold compresses, and the graduated bath, which consists of a warm bath gradually cooled down after the patient has been placed in it. Each of these methods is adapted to some cases, and each of them has its special advocates, but there is little doubt that, for general use, the cold bath is by far the best.

According to Brand, whenever the patient's temperature exceeds 102.2°, he should be put into the bath, the temperature being taken in the rectum. The temperature of the water is between 65° and 70°. Usually this will be well borne for ten or fifteen minutes, and it should ordinarily not be discontinued until a distinct shivering has begun, its effect on the pulse, meanwhile, being carefully watched. The temperature continues usually to fall for some time after the patient has been removed from the bath. The frequency with which the bath must be repeated will vary with individuals, but it should always be resorted to when the temperature reaches 102.2°.

My own experience with this method is so insignificant, as compared with the statistics collected by Brand, that it seems hardly worth while to do more than allude to it. About three years ago the New York Hospital had a bath-tub constructed for me, on wheels with rubber tires, so that it could be brought noiselessly to the bedside for use when required. It requires the services of two able-bodied attendants properly to administer a bath. The water need not, of course, be changed for every bath. I can only say that I have employed the method in a small number of cases, and am quite satisfied with the results obtained in this way. Not only is the fever thus reduced, but many of the graver symptoms are ameliorated, such as stupor, insomnia, delirium, feebleness of the heart's action with its pulmonary sequences, bedsores, and meteorism; and the mortality is unquestionably reduced, as the statistics which I have quoted show.

I have seen a general pulmonary œdema disappear almost as if by magic, under persistent application of cold water. It seems to have no influence, either for good or evil, over the occurrence of intestinal hemorrhage and perforation, and though we are forced to admit that its use is followed by a greater tendency to relapse, still relapses, as a rule, are of small consequence as compared with the many advantages of the method.

The temperature of the body is then markedly reduced; more in light cases than in severe ones; rather more markedly late in the disease than early. The fall in temperature begins when the patient is

removed from the bath, and continues more and more marked for an hour or two, when it again begins to rise, and may reach a height, in the earlier period of the disease, somewhat above that at which it was before the bath. In the later stages this is unusual. The frequency of the pulse is often diminished as much as twenty beats in the minute.

Under this treatment, the acidity of the urine is diminished, this sometimes even becoming alkaline, and often the solid ingredients of the urine are diminished, this indicating a diminished destruction of the albuminous tissues. Albuminuria becomes less frequent. From theoretical reasoning, it would seem unquestionable that such changes must have a good influence on the course of the disease. The excitement of the nervous centres being thus temporarily calmed, they are thus susceptible of a normal or nearly normal nutrition, the danger of collapse being thus materially lessened.

The practical proof which is given by the statistics of results under different methods of treatment seems quite in accord with these theoretical deductions.

The effect of high temperature is very deleterious upon normal tissues, and its influence is distinctly evil in reference to the possible healing of intestinal ulcers. Every surgeon knows that wounds are apt to act badly under the influence of fever, and it would seem to need no further argument than this to induce us to produce these artificial remissions of fever.

Whether to use the cold bath for a few minutes, the tepid bath or the graduated bath for a longer time, or the wet pack or cold sponging, or Leiter's tubes, which form the latest modification of the antipyretic method, are questions which the circumstances surrounding each case must enable us to decide. Enough has been said and written of late years about the technique of cold bathing. This must be made to vary with different cases; but one thing seems certain with regard to that modification of the plan which is most common here, namely, that cold sponging is in many cases wholly inefficient in the reduction of temperature.

Many lives have been lost by a timid temporizing with this modification, the physician lulling his conscience to sleep with the thought that he is resorting to a useful procedure, and the friends of the patient being content that much is being done to save him, his temperature meanwhile not falling appreciably under its use. My experience with Leiter's tube or coil is more unsatisfactory in this disease than with cold sponging.

It is not claimed that all cases can be safely or properly subjected to prolonged cold bathing. As contra-indications, may be mentioned intestinal hemorrhage, or perforation, or peritonitis; aphonia from ulceration of the larynx, which may threaten œdema of the glottis; marked degrees of heart weakness, in which the internal temperature is high, with cool extremities, pulse and heart impulse being very weak; also, venous congestion from chronic bronchitis, emphysema, and heart disease.

Menstruation and pregnancy are not contra-indications.

Besides these classes of cases, experience shows that certain patients, chiefly women, do not stand cold applications well, and in such cases the treatment after trial is not to be persisted in; but it is my belief that these cases are not common.

Of the use of antipyretic drugs in doses sufficient to reduce the temperature I am not an advocate, and I fail to interpret correctly the therapeutic indications of the times if they are not being less and less frequently resorted to. One cannot give large and frequently repeated doses of quinine, salicylic acid, or kairin without incurring the risk of seriously disturbing important functions. The use of carbolic acid in this disease is occasionally attended by very unpleasant consequences, and the results obtained by it do not seem to warrant us in continuing its administration either hypodermically or otherwise.

And now, Mr. President, having trespassed so long upon the time of the Society, I will not venture further to detain you by dwelling upon the various complications that may require treatment. I feel sure that you are waiting impatiently for those who are to follow me, and I will, therefore, content myself with merely calling attention to some of the important symptoms that require attention. These are nervous irritability, insomnia, headache, retention of urine, diarrhœa, perforation, peritonitis, tympanites, constipation, bronchitis; and I will close with the remark that those of us who habitually resort to the antipyretic method are rarely called upon to treat most of these complications, for it is well recognized that in patients thus treated but few of these symptoms habitually occur.

PROLAPSUS OF THE URETHRA.

BY R. H. DAY, M.D.,
OF BATON ROUGE, LA.

IN the report of my case of prolapsus of the urethra, published in THE MEDICAL NEWS of December 1, 1883, I stated that I had a second case under treatment, which I would keep under observation, and report the result.

This second case was brought to me about two weeks subsequently to the first. The patient, also a colored child, only fifteen months old, otherwise healthy, had a small prolapsus of the urethra, about the diameter of a nickel, slightly compressed laterally by the labia, making it somewhat elongated from above downward.

The mother stated that she had observed this protrusion for the past three or four months, and that it was slowly increasing in size. It presented all the physical appearances of the first case, except that it was much smaller.

The patient being quite young and in good health, and the prolapsus not causing much inconvenience, I determined to try to effect a cure without resorting to an operation. I accordingly commenced with acetate of lead, sulphate of zinc, and tincture of opium in aqueous solution, with which the tumor was directed to be sponged several times a day, and a pledget of cotton-lint wet with it applied in the interim. This was kept up for a week, and finding

but slight, if any, diminution in the size of the tumor, I changed my prescription to tannic acid dissolved in glycerine, to be kept applied on cotton-lint to the part. This acted favorably; the vascularity of the prolapsed membrane became less, by contraction of the capillaries and surrounding tissues, and in ten or twelve days was entirely retracted within the external opening of the canal, and the urethra presented a normal appearance.

Since my first case was published, I have been informed by Dr. M. D. Mann, of Buffalo, N. Y., that quite an able and exhaustive paper, covering this entire subject, had been written by Dr. T. A. Emmett, and was published in the *Transactions of the American Gynecological Society*. I regret very much that I did not know of, and had not seen, Dr. Emmett's paper when I reported my case, as it would have given me great pleasure to speak of his observations and skill in treating this rare disease, and of acknowledging the information and benefit I must have derived from an acquaintance with his views and experience.

In reviewing the history and particular features of the two cases, which I have seen, I am convinced in my own mind that the right line of treatment in each case, though entirely different, was based upon correct theoretical principles, and in each was promptly successful.

It may be thought by some, that inasmuch as the local application of tannic acid and glycerine was so successful in the last case, it might have been so in the first, and, if so, have saved the patient the risks of chloroform, and the possible accidents of even a simple operation. I would answer, that the size of the tumor in the first case, its extreme irritability, and the great pain and frequent efforts of micturition, made it necessary to adopt immediate operative measures for her relief, and hence justified any risks that were necessary in the procedure; still, in any subsequent case of this disease falling under my care, in which I can believe it is safe for the patient to delay, I shall certainly give the tannic acid and glycerine another trial, in view of their favorable action in the last case.

MEDICAL PROGRESS.

Septic Pneumonia of Young Children.—At the close of an article on this subject Silbermann draws the following conclusions.

1. The septic pneumonia of infants and nursing children, and which begins as a tracheo-bronchitis, is a catarrhal, and very often a foreign-body pneumonia.

2. It begins by the aspiration of decomposing amniotic fluid and genital secretions, or by the inspiration of strongly infected air from some septic disease of the mother.

3. Septic pneumonia of infants frequently accompanies diseases of the pleura, but seldom of other organs.

4. The alveoli and bronchi of the lungs of children dead of septic pneumonia are filled with bacteria.

5. The blood shows an increased amount of white globules, and a broken-down condition of the red.

6. Icterus is not a constant accompaniment of the disease.

7. The time at which the disease occurs is from one to two days after birth, and death usually takes place in about two days.—*Deutsch. Archiv f. klin. Med.*, December, 1883.

Sulphate of Copper in Obstetrics.—At the meeting of the Académie de Médecine, on March 4, 1884, M. Charpentier stated that he had employed sulphate of copper in obstetrics for some time, and from the experiments made in September and October, 1883, he draws the following conclusions:

1. Sulphate of copper, in solution of 1 to 100, is a good antiseptic, and may be of great service in obstetrics.

2. It is inoffensive to the patient, very cheap, and easily handled; it may be used for intravaginal or intra-uterine injections.

3. Sulphate of copper is both astringent and styptic, and may be used as a hæmostatic in place of Monsel's solution.

4. The solution used should be 1 to 100, and heated to about 96° F. It may be used for eight or ten days after parturition, repeated several times during the first twenty-four hours, if necessary. It lowers the temperature, and diminishes the frequency of the pulse.—*Journ. de Méd. de Paris*, March 8, 1884.

The Anatomy of the Hymen.—Dr. S. Pozzi has recently made a double series of anatomical investigations on this subject. First, on the embryo, in order to determine by sections the independence of the formation of the hymen, and the terminal parts of the ducts of Müller; and, second, on infants and adults, in order to dissect the masculine band (*bride masculine*) of the vestibule, and show its relations to the hymen. The conclusions which he draws from these investigations are as follows:

1. The hymen is an appendage of the vulva and not of the vagina; it is formed at the expense of the urogenital sinus, which also forms a short vestibular canal, this last being the entrance to the vaginal canal.

2. The name *bulb of the vagina* has been unwisely given to the lower part of the vascular plexus, which occupies a prominent position in that canal. There is no ground for distinguishing a distinct organ here, and it should not be compared to the bulb of the urethra in man. It may as well be said that the corpora spongiosa are the analogues of the labia minora.

3. An attentive examination of the vestibular region in woman will show a small band or frænum (*bride*) between the clitoris and the meatus, about two-tenths of an inch long in the adult, easily recognized by the rectilinear outline of its borders, marked by a median furrow, and divided inferiorly so as to encircle the meatus. When the hymen exists, it appears to be continuous with this frænum. Pozzi proposes to call this small band, now described for the first time, the male frænum of the vestibule (*bride masculine du vestibule*).

4. The study of the balano-urethral frænum—so noticeable in cases of hypospadias—shows the identical connections between that large band and the atrophied frænum (*bride*) of the female vestibule.

The bifid condition at the meatus and its continuity with the hymen are easily shown. But in hypospadias it

is clear that the frænum is a vestige of the corpus spongiosum arrested in the embryonic stage. The hymen of the hypospadias then, proceeding from the frænum, s an appendage of the corpus spongiosum, and is the terminal part or bulb. This conclusion may be applied to the female organ, and it may be said that *the hymen in the female is the analogue of the bulb of the urethra in man; it is the bulb arrested in the fœtal state, non-erectile, and membraniform.* [Henle has noted the frequent presence of cavernous or erectile tissue in the hymen.]

5. The connections of the gland of Bartholin to those of Cowper may be also easily made out. The considerable length of the excretory canal for the male glands, compared with their shortness in the female, should be especially considered. This admits of the opening of the canal considerably in front of the membranous region, at a certain distance in front of the posterior part of the bulb; that is to say, at a point exactly corresponding to the opening of the duct of Bartholin, in front of the hymen, at a certain distance from the fourchette. The opening of Bartholin's gland in the prehymeneal portion of the vulva is the origin of that singular lengthening of Cowper's duct.

6. The male frænum of the vestibule in woman is the vestige of the anterior or cylindroid portion of the corpora spongiosa, just as the hymen is the vestige of their posterior or ovoid portion.—*Gazette Méd. de Paris*, February 23, 1884.

PORRO OPERATION ON ACCOUNT OF TUMOR OF THE CERVIX.—DR. DENARÉ reports (*Lyon Méd.*, 1883, No. 20) the case of a woman, æt. forty-two years, who had had thirteen children and two miscarriages. She was now in labor for the sixteenth time. On examination a hard tumor was found in left iliac fossa; it was large, sprang from the posterior lip of the cervix, and between it and the anterior pelvic wall there was scarcely room to admit a finger. On November 23, 1882, three days after the first pains, the Porro operation was performed. The fœtus was found to be macerated. The woman recovered.—*Centralb. f. Gynäk.*, February 23, 1884.

THE RADICAL CURE OF INGUINAL HERNIA.—MR. J. K. BARTON, in a paper on this subject, refers to the *direct method* as described by Prof. S. D. Gross, and reports three cases. The first was that of a boy, about three years old, who had an enormous ingüinal hernia, which could not be kept in place.

An incision, two inches in length, was made obliquely from above downwards and inwards, its upper extremity corresponding to the internal ring; the fascia was carefully divided upon a director, and when the internal ring was reached the index finger of the left hand was introduced into it, so as completely to prevent the descent of the hernia, and, at the same time, to regulate the next step, which was the introduction of the wire suture; and for the remainder of the operation the finger maintained this position. A curved needle, with the eye close to the point, was then passed through the inner pillar of the ring (care being taken not to introduce it too near its free edge), and, guided by the left forefinger, was safely carried across the ring and through the outer pillar from behind forwards; a strong silver wire was then passed through the eye, and the needle was withdrawn; thus the first wire stitch was introduced and similarly a second—only two were placed in this case—the finger was then withdrawn, and the wire was tightened, drawing the sides of the ring into close contact. When firmly secured by twisting, the cut ends were carefully bent down so as to lie in the axis of the wound, and not project either forwards or backwards. Drainage was provided for by a few catgut threads, the wound was then closed, and dressed with protective and gauze. This case subsequently ruptured again, but the other two, upon which the same operation was performed, were complete successes.—*Dublin Journ. of Med. Sci.*, February, 1884.

THE CAUSE OF ABORTION OR PREMATURE LABOR.—In an interesting discussion on the reciprocal influence of traumatism and pregnancy, before the Société de Chirurgie, in 1876, it was conceded that: 1. The true predisposing cause of abortion is irritability of the uterus, that is to say, the property possessed by the tissue of that organ of responding, by virtue of contractility, to external or internal stimuli, whether direct or indirect. 2. When the woman, the uterus, and the ovum are sound, this property is but slightly developed, and traumatism has but little influence in causing abortion or premature labor. In these favorable conditions, experience has shown that injuries, falls, blows, and severe surgical operations are not likely to cause these accidents, unless the genital apparatus itself is involved. 3. The causes producing inability of the uterus, and, consequently, which cause that organ to contract and expel its contents, are: *a*, Diseases or lesions of every nature which affect the uterus; *b*, diseases of the ovum, affecting the placenta, the cord, or the fœtus, death of the fœtus, and hydrops amnii; *c*, certain general morbid states affecting the mother, comprising acute diseases, as typhoid fever, the eruptive fevers, cholera, and various epidemic influences; and chronic diseases, of which the principal are albuminuria, constitutional syphilis, the various cachexiæ, constitutional or acquired feebleness, saturnine or paludal poisoning, chloro-anæmia, etc. According to Guéniot, these general causes may act in two ways—either directly, by causing uterine irritation, on account of the local state of the organs, or, indirectly, by altering the ovum.

Among the chronic diseases causing abortion, says DR. F. VINCENT, chloro-anæmia merits special attention, as it exerts a marked influence on the whole system. Of the functional troubles, those of the nervous system play the most important part. In certain cases the nervous symptoms assume a very grave character, and the malady is complicated by spasms, such as chorea, epilepsy, paralysis agitans, and even by mental alienation. Furthermore, chloro-anæmia is remarkable in that it complicates most of the chronic diseases mentioned above, notably those affecting the nervous system, as: 1. Albuminuria (so frequently a cause of eclampsia during pregnancy or labor). 2. Saturnine intoxication. 3. Mercurial cachexia. 4. Constitutional syphilis. 5. Paludal intoxication. 6. Hysteria in all its forms. It may be considered as an established fact that chloro-anæmia renders the nervous system very impressionable to outside influences, and it would seem that an essential neurosis may exert the same effect in causing abortion as an acquired neurosis.—*Journal de Méd. de Paris*, February 16, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 5, 1884.

EMMET'S OPERATION FOR LACERATION OF THE CERVIX.

IT has been said that a new operation usually passes through three periods in regard to professional favor. In the first it is decried; in the second it is unduly commended; while in the third it is given its just appreciation. Dr. Emmet's operation for laceration of the cervix—an operation now hardly fifteen years old, has probably not completed the second period mentioned, at least so far as this country is concerned; it still occupies a higher position, we believe, than that which will be ultimately assigned it.

Yet we do not for a moment suppose that Dr. Emmet would now say, as he did in the last edition of his *Gynecology*, that the operation should be done in every case in which the laceration, though healed, is evident, and in which the womb is enlarged, or in which the patient has neuralgia—a liberty of operating that in some hands may have become a gross and mischievous license. This doubt is a conviction when we read the following statement from Meyer Leopold—*Revue des Maladies des Femmes*—who recently visited this country: "Dr. Emmet has greatly modified his view of the utility of the operation, now limiting it to those cases in which the rent extends to the cellular tissue lining the vaginal cul-de-sacs, causing a peri-cervical inflammation, and hence this parametritis is regarded as the essential point of all the evil." This inflammation causes the eversion, and that eversion demands the operation. Leopold goes on to say that a laceration not involving the cellular tissue lining the vaginal cul-de-sacs does not merit the attention of the surgeon; and still further, that eversion of the lips of the womb and exposure of the cervical mucous membrane are phenomena observed independent of all tearing of the cervix—it is the pathogenetic process of change of the mucous membrane, and of the ulceration of the cervix which is its consequence; a morbid state which can be remedied much more usefully, and, especially, much more permanently, by excision of the mucous membrane and deep ignipuncture. Even in cases in which there is cicatricial ectropion, Leopold holds that other means are better than tracheloplasty.

Without endorsing in full Leopold's views, it is very evident that our distinguished countryman, Dr. Emmet, does not attach such importance to his operation as he once did, and very much less than some who supposed themselves his faithful followers. We look now for that reaction which will assign the proper place to the operation, for some have made lacerations of the cervix almost the alpha and the omega of their uterine pathology, and plastic operations for the remedying of these tears almost the alpha and omega of their uterine therapeutics. Women have been made unhappy by being told that they were so badly injured in their labor that they could never be well until the torn womb was sewed, and sometimes, possibly, unjust reproach cast upon a competent and careful obstetrician who had attended them in labor.

Hardly one woman in five hundred gives birth without some tearing of the cervix; the virgin os, the nulliparous os is lost in labor, and is never restored; in fact, the distinction between anterior and posterior lip of the the womb is without existence prior to childbirth, while it is normal afterward, and therefore in almost every woman who has borne a child one or more tears, healed or unhealed, can be discovered by expert finger and eye. The traumatism in this, as in so many of the sex-functions of woman, is physiological. Her first sexual intercourse is often attended with traumatism; traumatism marks every monthly period, the uterus, and one or the other ovaries is then wounded, and these latter organs carry until the body moulders in dust the scars of traumatisms, to which they have been periodically subjected for thirty years; it would be as needless to endeavor to restore these scarred and seamed ovaries to the condition in which they were before menstruation, or to devise a hymenoplastic—of course, gyneocologists will be grateful for a new Greek compound, their science is so poor in such treasures—operation, as to restore the parous to the virgin cervix. We have never believed that woman's uterus was so imperfectly formed, or that obstetricians were so ignorant, so meddlesome, or so mischievous in their practice, that a large percentage of women in the martyrdom of maternity

had the cervix so seriously torn that a surgical operation was necessary to repair the injury.

We are aware that the operation pompously decorated as hystero-trachelorrhaphy—it ought to be tracheloplasty, rather than trachelorrhaphy, as it is more than the simple introduction of stitches—is usually neither difficult nor long. But we further know that the immediate consequences are not always so simple and safe as most writers upon the subject have generally found them, for without seeking to learn untoward results, we know of two cases in which dangerous secondary hemorrhage occurred, others in which the operation was followed by serious pelvic inflammation, and four unpublished cases in which the patients were dead within a week.

But we are told of remarkable cures. Certainly in those cases in which the operation was plainly indicated—and we are not sure these constitute a majority of all that have been operated upon—the results have been most satisfactory. Then as to others, in which various neurotic disturbances have been relieved or cured by tracheloplasty, the thoughtful gynecologist may see only the result of a profound mental impression. Other patients are cured by the operation simply because the removal of even a small portion of hypertrophied cervix hastens absorption, and thus lessens the size of the part. Still others are, at least for the time, relieved simply by the local depletion attendant upon the operation and the prolonged rest which follows it. There remain some cases in which neither the patient nor the physician will discover any permanent good from the operation—both are disappointed. This fact we state from our own experience, from the observation of cases operated upon by others, and from the testimony of some operators themselves.

Just now the profession, in this country at least, does not so much stand in need of the voices of the enthusiastic advocates of Emmet's operation—some of whom are doing it in cases in which he he would not—as the calm conclusion of the saving remnant who seek to render exact justice to every advance in medical and surgical therapeutics.

INTERNATIONAL COPYRIGHT.

EVERY few years the question of granting American copyright to foreign authors comes to the surface and agitates the literary and publishing world. It is the natural and inevitable effort to redress a wrong of which the nation is guilty, and its recurrence at frequent intervals is to be expected until that wrong is removed. We are now in the midst of one of these periodical movements, and as the medical profession is largely composed of thoughtful reading men, to whom books are a necessity, a few words on the subject may not be amiss.

It is now three years since the last attempt was made to obtain international copyright, by what was known as the "Harper Treaty." That attempt was abandoned for reasons that were never publicly known, but its failure was attributed, apparently with reason, to the hostility of the English publishing interests to the clause requiring all books copyrighted in this country to be manufactured in this country—a provision which would seem reasonable alike for the interests of many thousands of operatives dependent upon the book-manufacture and of millions of readers who would be unable to purchase books in the costly style in which they are habitually produced in England. Early in the present session the Hon. Mr. Dorsheimer, of New York, introduced in the House of Representatives a bill granting American copyright to the authors of all countries which should grant equal and similar privileges to American authors. This bill is understood to have been drawn up by the "American Copyright League," a body formed for the purpose of securing legislation on the subject, and claiming a membership of about six hundred gentlemen, comprising nearly all the professional authors and leading journalists of the country. So large a body, thus composed, must necessarily exert no little influence, not only on account of the character of its members, but also from the fact that it controls in large part the organs of public opinion, the means of reaching the public, and the channels by which the public can make itself heard. The bill thus fathered was somewhat ostentatiously proclaimed to be purely an author's bill—a bill designed to secure the rights of authors in their literary property at home and abroad, regardless of the effects which the proposed legislation might have upon the interests of the public at large.

Copyright, like patent-right, is so purely artificial a creation, springing from modern inventions, which render the indefinite multiplication of books a possibility, and from the modern spread of education, which renders the multiplication of books a source of profit, that it has not yet reached the stage of legal recognition as an indefeasible right inherent in authorship. It is thus far the creation of statutes which professedly bestow it on the author, not for his own benefit, but for that of the public. This is expressly stated in the article of the Constitution of the United States which confers upon Congress the power to grant copyright, and thus is the only source through which copyright can be enjoyed in this country. Whatever may be the case in the future, the public is thus not yet prepared to grant additional and far-reaching rights to authorship without inquiring as to the effect which those

rights would have upon the interests of society in general. It was seen that the result of Mr. Dorsheimer's bill would be to make the United States virtually dependent upon England for its supply of future English literature, and it was felt that when English publishers should hold the monopoly of the American market, they would not be likely to adapt their forms of publication to the tastes of American readers nor to limit their profits by the requirements of the masses in this country, who want good literature, but who have been accustomed to procure it at prices almost nominal, as the result of unlimited competition. The trades interested in book-manufacture—the printers, paper makers, and others—moreover, took the alarm, and urgently protested against a measure which would so seriously cripple them.

Various amendments have been proposed to Mr. Dorsheimer's bill, with a view to reconcile as far as possible all conflicting interests—to secure substantial justice to authors without bearing too hardly upon readers and producers. These amendments are designed, in one way or another, to secure the manufacture of copyrighted books in this country, and thus to have them issued in forms and at prices suited to the necessities of American readers. Unfortunately, thus far Mr. Dorsheimer and his friends have refused to accept any such modifications of the measure, although they have not been able to show that the proposed changes would in any way prove injurious to authors, either at home or abroad.

The fact is that the American author is already well secured as to his foreign rights. By the liberal construction of the English law he can obtain a copyright in Great Britain on the simple condition of first publication there; and through his English copyright he has copyright in all countries with which Great Britain has copyright treaties. At home, however, he is subjected to the destructive competition with English literature, which can be had gratuitously, and is reproduced at the lowest practicable rates. From this competition he has a right to ask for relief, and that his natural market shall not be forestalled by supplies thus unrighteously cheapened. The English author, too, has ample ground for complaint in seeing his productions seized without leave and indefinitely reproduced without, in many cases, yielding him benefit. In fact, the only advantage he reaps from the greatest market of the English-speaking race is derived from the honorable feeling of those publishing houses who are wont to recognize an obligation that is not enforced by legal sanction, and this is a position from which he, too, has a right to ask for relief. Both of these crying wrongs would be removed by any form of international copyright, whether it requires home manufacture or not, and it is not easy to understand the persistence with which Mr. Dorsheimer and his friends refuse to permit any modification of their measure.

At this present writing the probabilities would seem adverse to the passage of any copyright measure at the present session. Should this prove to be the case, the responsibility will rest upon those who decline to recognize that the public has any claim to be heard, or that its interests are in any way to be taken into account. Yet the movement, even in such case, cannot be regarded as a failure. It is not likely that the American Copyright League will disband or be disheartened by a temporary want of success. It will doubtless continue in existence, and perhaps before next session it may learn to look at the matter in a broader light, and frame a measure which shall command such general support that the reproach of disregarding authors' rights will be removed from our statute-book with scarcely a dissenting voice.

LIGATION OF THE COMMON ILIAC ARTERY.

In the *Centralblatt für Chirurgie*, No. 10, 1884, may be found the report of a successful ligation of the primitive iliac artery for aneurism of the internal iliac, by Professor Schoenborn, in which the catgut ligature and antiseptic precautions were employed. In 1883, Dr. Packard recorded a fatal instance, with a statistical table of sixty-seven cases, in the first volume of the *Transactions of the American Surgical Association*, and Dr. Kümmell reported to the twelfth *Congress der deutschen Gesellschaft für Chirurgie* one recovery and one death from his own practice, along with an analysis of sixty-two cases. Having made a careful examination of these papers, and added other examples which have escaped the notice of these surgeons, we are enabled to lay before our readers the results of 79 cases, which do not, however, include those of Beugnot, Dumreicher, Lemprière, and Medoro, the original references to which are inaccessible.

Grouping the cases into four classes, we find that the vessel has been tied for the following conditions: First, for hemorrhage, whether primary or consecutive to the ligation of other trunks, or during the performance of other operations 28 times, of which 4 recovered, and 24, or 85.71 per cent., died. The operators were Baudelocque, Blandin, Brainard, Buck, Busch, Carr, Czerny, De Lisle, Edwards, Gibson, Gilpin, Garviso, Hamilton, Holt, Ingram, Kümmell, Kümmell, Liston, McKee, McKinley, A. B. Mott, Mowret, Packard, Parker, Pirogoff, Post, Uhde, and Von Langenbeck.

Secondly, for the cure of aneurism 43 times, with 15 recoveries and 28 deaths, or a mortality of 65.11 per cent. The operators were Barbosa, Barral, Baxter, Bickersteth, Briarly and Hammond, Caldas,

Cock, Crampton, Cutter, D'Almeida, Garviso, Goldsmith, Gouley, Hargrave, Hey, Hunter, Isham, Jones, Knorre, Ladureau, Lange, Luzenberg, Lyon, Maunder, Mayo, A. B. Mott, V. Mott, Nicoladoni, Peace, Pitta, Richter, Salomon, Sands, Schoenborn, H. Smith, Stephen Smith, Stevens, Stone, Sulzenbacher, Syme, Syme, Van Buren, and Widderburn.

Thirdly, for pulsating tumors simulating aneurism 5 times, of which 1 recovered, and 4, or 80 per cent., died. The operators were Baker, Guthrie, Meier, Moore, and Stanley.

Fourthly, as a preliminary step to prevent hemorrhage during the removal of a tumor or amputation at the hip-joint 3 times, of which all were fatal. The operators were Bünger, Bushe, and Chassaignac.

With such a gloomy record before us, namely, a mortality of 74.68 per cent., we cannot endorse the view of Packard that it would probably be sound surgery to resort to preliminary ligation of the common iliac artery to prevent hemorrhage in amputation at the hip; nor can we agree with Kümmell, who holds that the procedure is preferable to ligation of the external iliac, for aneurism of that vessel seated high up, and of the femoral artery, because it is far less liable to be followed by gangrene of the lower limb than the latter operation.

THE PATHOGENESIS OF IDIOPATHIC ULCERS OF THE LEG.

IN a recent brochure, M. SCHREIDER attributes the occurrence of spontaneous ulcers of the leg to nutritive disturbances brought about by certain primary degenerative changes in the vascular system, and secondary alterations in the nerves of the part. In all of the cases examined he found, in the order of their appearance and succession, first, phlebectasis of the superficial and deep veins, which becomes apparent between the ages of twenty and thirty; second, atheromatous degeneration of the arteries, which manifests itself, as a rule, between the fortieth and fiftieth years; and, third, alterations in the local nerves, provoked by sclerosis of the tissues, which sclerosis is the natural result of the vascular disturbances. The part played by the nerves in the etiology of the affection is demonstrated by the general, tactile and thermal sensibility; and the disorders which the nerve lesion evokes are analogous to the purely trophic disturbances met with in diseases of the central nervous system and ascending neuritis..

MICROCOCCI OF PNEUMONIA IN SPUTUM.

As far back as June, 1883, DR. FRANZ ZIEHL (*Centralbl. für die med. Wissensch.*, No. 25) called attention to the fact that the micrococcus of pneumonia could be recognized with comparative ease in the sputum of that disease. Still more recently (*Ibid.*, February 7, 1884) he reiterates this statement. The distinctive feature of this micrococcus is the hull or capsule of mucous or gelatinous substance which Günther was the first to discover, and which Friedländer also describes as being very characteristic. It is extremely rare upon other micrococci; in fact, as good as absent in all other micro-organisms found in the human body, except the lepra bacilli, from which its shape easily distinguishes it. This capsule may surround a single coccus, or it may contain again two, three, four, or even more. It is not, however, invariably demonstrable, because from some cocci it is absent, and in certain others it is not easily discerned, while sometimes empty capsules are found. Specimens are best prepared by treating the dried sputum with a watery solution of gentian violet, and examining the colored preparation in a drop of water.

The demonstration of these micrococci in sputum, says Ziehl, has not merely an etiological, but also a diagnostic value, as they are found even before the physical signs are distinctive, or the rust-colored sputum has made its appearance; and when it is remembered how often these symptoms are wanting when the physician is first called, we may have in the finding of the organism in the sputum of pneumonia an assistance to diagnosis just as valuable as the bacillus of tuberculosis.

SYPHILITIC REINFECTION.

IN a series of contributions to the *Wiener medizinische Presse*, Nos. 1, 2, 4, and 5, 1884, PROFESSOR NEUMANN discusses the highly important question as to whether syphilis can be acquired more than once, an occurrence which has not been witnessed by Bärensprung, Sigmund, and Fournier, but has been met with by Diday, Zeissl, Bumstead, Hutchinson, Lee, and other equally careful and experienced syphilographers.

From a critical examination of the recorded examples of reinfection, Neumann reaches the conclusion that, although syphilis usually occurs but once in the same subject, cases of undoubted reinfection have been observed, but that they constitute only about one-half of the recorded instances of a second outbreak. The criteria of reinfection are a clear history of the first infection, an initial lesion, enlargement of the inguinal glands, and subsequent secondary manifestations. A sore following coitus may be a relapsing induration, a gumma, or a chancroid, the last of which lesions exhibits a marked tendency to an indurated base in syphilitic patients, so that a hard lesion seated on the genitals, without concomitant adenopathy and consecutive constitutional symptoms, is not an indication of a second attack.

REVIEWS.

What to do First in Accidents and Emergencies; a Manual Explaining the Treatment of Surgical and other Injuries in the Absence of the Physician. By Charles W. Dulles, M.D., Fellow of the College of Physicians of Philadelphia, etc. Second edition, revised and enlarged, with new illustrations. 12mo. pp. 119. Philadelphia: P. Blakiston, Son & Co., 1883.

This handy little volume makes its appearance in a second edition, which has been revised and enlarged and freshly illustrated, so that, in its present form, it is practically a new book.

It is written for the public, and the suggestions it contains are simple and practicable, so as to be easily comprehended, and readily acted upon whenever an emergency may arise. A very complete index has been provided, and, as a further aid to prompt reference, the topography has been so arranged that leading words may catch the eye on every page.

The preparation of such a book is not an easy task. It requires familiarity with every possible contingency, and the exercise of good judgment, wise discrimination, and the faculty of suggesting and adapting the simplest means to the end in view. The object of the book, to supply such information as may be of service during the interval between the occurrence of an accident and the arrival of one professionally qualified to take charge of the case, must be kept steadily in mind, so as to introduce nothing which will have a tendency to impart to the inoffensive bystander the power of officious and hurtful meddlesomeness.

Dr. Dulles has brought to the performance of his task a felicitous combination of the needed qualifications, and his little book can be safely recommended as one of the best of the kind to be placed in the hands of the public.

SOCIETY PROCEEDINGS.

RHODE ISLAND MEDICAL SOCIETY.

Quarterly Meeting, held in Providence, March 20, 1884.

(Specially reported for The Medical News.)

The Society met in Lyceum Hall, Providence, March 20th. The President, Dr. Job Kenyon, in the Chair.

The Secretary, Dr. Geo. D. Hersey, read the record of the December meeting, which was approved.

Dr. Neil O'Donnell Parks read a paper upon

topical cardiac blistering in the treatment of acute rheumatism.

He had employed this mode of treatment in seven cases, and in one of them no other measures whatever were used; the result being in this, as in the other cases, a prompt and complete cure. In the remaining cases, salicyn, or one of its allied compounds, and ammonium carbonate were given internally. Oleum gaultheriæ was used in some instances—internally in doses of fifteen drops once in two hours, and applied locally to the inflamed joints, combined with an equal amount of lin. camphoræ comp. The series described included cases of acute articular rheumatism, and rheumatic gout, so called. In some of the cases an endocardial murmur was present. Usually, one blistering sufficed, but in case of relapse it was repeated. The writer expressed his belief that we have, in the method under consideration, a most valuable adjunct to our means of successfully treating rheumatism.

Dr. H. Terry read a paper upon the

prevention and treatment of puerperal fever.

A most important preventive measure is to secure the prompt and firm contraction of the uterus immediately after delivery, and the attendant should guard against temporary relaxation and partial dilatation for at least half an hour, or until the condition of firm contraction becomes established. The application of cold to the abdomen, pressure, friction, ergot in small doses, and a carefully applied binder, were named as means to be employed. The writer objected to the repeated use of an antiseptic vaginal douche before delivery, as it must necessarily wash away the mucous secretion and keep the vagina so *dry* as to retard labor, and increase the danger of rupture of the soft parts. Belief was expressed in the *septic* origin of puerperal fever, and that *milk* fever is also a mild type of septic fever. He had used as injections only solutions of permanganate of potash and carbolic acid, and of the two he preferred the former. In one case cited, the douche was continued for ten days, and brandy, ʒij–v, was given hourly with quinine, anodynes, and tonics, as indicated. If the first intra-uterine injection does not prove beneficial, it should not be repeated.

Dr. Lloyd Morton, of Pawtucket, exhibited a specimen of

impacted intracapsular fracture of the neck of the femur.

The patient was a woman, seventy years old, and the injury resulted from muscular strain, and not from direct violence. At the time of injury, there was no shortening, no crepitus, no preternatural mobility, and the patient could even rotate the thigh. A correct diagnosis was made, however, by exclusion, as was shown, post-mortem, four weeks later, death resulting from causes independent of the injury.

Dr. H. G. Miller, of Providence, read a paper on

blepharospasm.

He made four forms in his classification, according to the degree and severity of the case.

1. A simple spasmodic contraction (clonic) of the upper or lower portion of the orbicularis muscle—oftener of the lower portion. This condition is regarded as occurring more frequently in hypermetropia than in myopia; but, in the writer's experience, myopic persons are more prone to complain of it. The cause of the symptom, however, is not always to be found in some refractive error, but may be fatigue of the eye or of some portion of the nervous organism, or the excessive use of tea or coffee, etc. The lids of one or both eyes may be involved in this type of the disease.

2. Nictitation, which involves the muscles of both sides, causing violent and too frequent winking. It is liable to occur in children, and hyperæmia of the lids and conjunctivæ may be the cause of it.

3. An exaggeration of the natural effort of the lids to cover and protect the eyes, due most frequently to photophobia, and rendering the palpebral opening smaller than normal.

4. Spasm of the orbicularis of one side, and likewise of all the muscles supplied by the facialis nerve. Usually some twig or branch of the trigeminus is the primary seat of the trouble—in the teeth, jaws, or even the external auditory meatus. Again, it may be due to epilepsy, chorea, or traumatism. It may be of centric origin. It may be congenital, and accompanied by nystagmus. In children, intestinal worms, both lumbrici and ascarides, may be the cause. The result of this one-sided spasm is often to give the patient an appearance of adding a mysterious significance to his conversation, or, what is more serious than such disfigurement, amblyopia may be caused by it. He had observed in one case a row of abrasions of the cornea corresponding to the line of pressure of the lid.

In both the upper and lower lids are certain smooth muscles, spasmodic action of which tends to increase the palpebral opening, and expose the sclerotic beyond the conjunctival margin, and giving the peculiar staring expression sometimes seen, especially among some classes of insane patients.

Three cases were then mentioned:

Case I.—A man, thirty years old, seven months ago began to suffer from contraction of the right eyelids. The trouble soon extended to the left eye. Apparently, his general health was perfect. The spasmodic contraction in this case was so severe as to cause the corneal abrasions already referred to. He had found that any unusual excitement or diversion of his mind, such as playing on his violin, riding in the street-cars, etc., would enable him temporarily to relax the eyelids, when the eyes would resume their natural appearance.

None of the remedies as yet tried had effected permanent relief in this case. The ext. c)nii fl. (Tilden's) was given in doses increasing from gtt. v to gtt. xxx or xl; and subsequently Squibb's preparation, in doses going as high as gtt. lxx—all with no benefit. It yet remains to employ the method of Dr. Wordsworth, of dividing or stretching the lids outwards.

Case II.—A sempstress, aged twenty-one years, and hypermetropic in a high degree. Her eyes became useless from spasm of the lids. By correcting the refractive error with glasses, and the administration of bromide of potassium very nearly a complete cure had been accomplished.

Case III.—Man, forty years old, and myopic. Suffered severely from contractions of the eyelids and twitching of the face. Careful examination revealed myopic astigmatism of one eye, with myopia of the other. Correction of both by glasses led to a complete and permanent cure.

A case was also cited which was reported to have occurred in Belgium. Here the upper lid was so firmly contracted over the eye as mechanically to obstruct vision. The treatment was to make a permanent elliptical opening through the lid, opposite the pupil, through which the patient was again able to see.

DR. O'LEARY asked if injury to the facial nerve ever destroyed the sight, and spoke of an army officer whose face was grazed by a Minie-ball, causing a slight abrasion of the skin at the eyebrow, but very little pain. The sight of that eye, however, was immediately and permanently lost.

DR. MILLER said that, in such a case, he should regard the loss of vision as probably due to concussion of the retina; but that, indirectly, injury to the facial nerve may destroy the sight.

DR. BURGE read a report of a case of

DISEASE OF THE BLADDER, PROBABLY MALIGNANT,

The man was about sixty years of age, who attended to business until a few days before his death—nearly all the symptoms of stone had existed for some time. No urine was voided for five days before he died. The autopsy revealed a dense, whitish growth inside the bladder, occupying a surface as large as a half dollar, and so involving both ureters as wholly to occlude them.

DR. CASWELL said that he was associated with Dr. Burge in the case just reported. The bloody urine, containing crystals of oxalate of lime, frequent micturition, and pain in the end of the penis, had led him strongly to suspect the presence of stone, but a careful examination with a Thompson's searcher discovered none—a roughened surface could be felt, however. Not long after the examination the patient said he voided a small stone, which was lost. Dr. Caswell remarked, at this point, that, owing to congenital phimosis, he had been able to use no larger instrument than the one named above, in his examination for stone, and had decided to operate for the cure of the phimosis, but the patient grew worse and died in a few days. He thought it much better, when the presence of a *small* stone is suspected, to introduce, if possible, one of the tubes of the Bigelow evacuating apparatus, and wash out the bladder, as it is probable the stone would be brought out or at least engaged in the eye of the tube and removed in that way. He had made a careful microscopic examination of the growth found in the bladder in this case, and thought it to be a fibro-sarcoma, and that death resulted from the mechanical obstruction it caused rather than from its constitutional effects. The specimen was shown.

Dr. Caswell also spoke of a case which he had recently operated on at the Rhode Island Hospital. The man, twenty-seven years old, had had abscesses and fistulous openings in the perineum for two years. No stricture existed, a sound (No. 24, French) passing naturally into the bladder. He decided to operate for the cure of the three perineal fistulæ. On opening up one of them, seven small calculi were found which seemed to be fastened to the roof of the fistulous tract, where they had probably formed. These were about the size of small peas, round, rough, and of a whitish color. He was not certain whether they were oxalate or urate of lime.

DR. MORTON said, relative to the proposed

LAW FOR MEDICAL EXAMINERS,

that the bill was now before the Legislature, and would probably be enacted this session, but that the form approved and submitted by the Medical Society had been subsequently so far modified as to continue the office of coroner, and provide for medical examiners also. This was due, he said, to the great fondness that seems to prevail among the people and the legislators for the time-honored name and function of the coroner.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, March 17, 1884.

THE PRESIDENT, WILLIAM DETMOLD, M.D., IN THE CHAIR.

DR. GEORGE L. PEABODY read a paper on the

TREATMENT OF TYPHOID FEVER.

(See THE MEDICAL NEWS, March 29th, page 355, and April 5th, page 383.)

DR. AUSTIN FLINT, JR., in opening the discussion, said that the subject of animal heat was one not only of great physiological, but also of great pathological interest; and that any measures intended to counteract a body-heat transcending the limits of normal temperature should be based on a knowledge of the physiological production of heat. There is no physiologist at the present day who does not believe that heat-production is one of the results of a class of phenomena occurring in the tissues themselves, and that heat is not supplied to the tissues by the blood. Formerly, however, it had been the accepted opinion that certain changes took place in the blood which elevated the temperature of that fluid. The lungs were supposed to be a kind of furnace in which the heat was manufactured, and the arteries, a set of flues to convey it to all parts of the body. But this was disproved by experiments; for it had been shown that the blood coming from the lungs was not hotter than that which was going to these organs. The seat of the heat-producing process, therefore, has been transferred to the tissues themselves, although it is still regarded as involving oxidation. As to the extraordinary production of heat met with in typhoid and other essential fevers, this was no doubt due to some change in the normal process which was not as yet understood. In modern physiology, the tendency is to reduce everything to mathematical exactness; and as regards the transformation of one force into another in accordance with the theory of correlation of forces, nothing is lost and nothing created. The result of the consumption of a certain amount of oxygen in the body is the formation of a certain amount of carbonic acid gas and the discharge of a certain amount of excrementitious material.

The heat-value of various elements of food has been determined by burning them in oxygen, the heat-unit being taken as the quantity of heat required to raise the temperature of one pound of water one degree Fah. The quantity of heat produced in the body has also been determined by the careful experiments of Senator and Prof. John C. Draper. The latter has ascertained that four heat-units are produced per pound weight of the body per hour. The law of the correlation of forces admits of the expenditure in the body of a certain amount of force as work; but there exist serious errors in connection with these calculations. Thus, in the transmutation of heat into force, one heat-unit is said to be equal to 772 foot-pounds; but the fallacy in the application of the law of correlation of forces has been in always considering the physiological processes from the point of view of the conversion of heat into force, while the formula that one heat-unit equals 772 foot-pounds was deduced by experiments converting force into heat and never heat into force. Some years ago, he had had the opportunity of making a series of observations upon a pedestrian while engaged in walking 317½ miles in five consecutive days. The food and drink which the subject of these observations took (every article of which was carefully weighed), with the loss of body-weight, represented 33,000 heat-units, while the heat actually produced equalled 55,000, so that there was a deficit of 22,500, or 40 per cent. In the year 1878, he himself had fasted for 33 hours, and during the last 24 hours of this period made careful observations, the first 9 hours being left for the disposal by digestion of the food already in the system. During this time 18,000 heat-units were produced, while the heat-value of the nitrogen of the urine and the carbon given off by the lungs was only 12,500 heat-units. There was thus a deficit of 5500. Afterward, he made a similar series of observations on himself for 24 hours, while taking food as usual, when he found that the difference between the heat evolved (18,000 heat-units) and the heat-value of the food taken (15,000 heat-units) was 3000 heat-units (no allowance being made for the work of the heart and of the respiratory muscles). Such facts seemed to render some modification of the theory of the production of heat necessary; and it became pertinent to ask whether water was not produced in the body by the union of oxygen and hydrogen. This was a question which was not incapable of solution by experiment, at least approximatively. It was, therefore, a point of great importance to show, if possible, that more water was discharged from the body than had been taken into it. In the case of the pedestrian before alluded to, while the body-weight at the beginning, with the ingesta, amounted to 2750 ounces, the body-weight at the end of the observations, with the urine, feces, and carbon discharged by the lungs, amounted to only 2100 ounces. The difference, 650 ounces, therefore, equalled the loss of water by the skin and lungs. In the five days, the total amount of water given off was 850 ounces; while the water in the drink and the solid food which he took amounted to 788 ounces; so that there was an excess of 62 ounces of water given off. Similar observations upon himself showed a like result. The production of anything, either heat or force, involved the consumption of material; and he had become convinced that this formation of water in the body by the union of oxygen and hydrogen was a most important factor in the production of animal heat.

In fevers there was an exaggeration of the normal heat-producing process. The fever fed upon the tissues of the body; and it necessarily followed that it must produce disastrous destruction of these tissues, unless there was something else for it to feed upon. The question, therefore, arose, how can such other material be supplied? The answer was, that it must be by means of food. Fuel for the flames raging in the system had to be furnished, and it had occurred to him that this might be best accomplished by the administration of fatty substances (such as cream and cod-liver oil, perhaps), farinaceous substances, saccharine matters, particularly glucose, and alcohol. Experience had already shown conclusively that alcohol, although a heat-producer, did not increase the temperature in fevers, but, on the contrary, diminished it. Theoretically, one ounce of French brandy was equivalent to three hundred and ninety-eight heat-units; and thirty-four ounces in the twenty-four hours would supply all the heat required in the body

of a man weighing one hundred and forty pounds. In looking at this matter from a physiological point of view, he had become so much impressed with its importance, that he was desirous to test it by treating a number of typhoid fever patients in the manner indicated. Cold baths, he thought, were useful; but if for the weeks that the fever lasted a sufficient amount of the material mentioned could be introduced into the system, he was convinced that, at the end of the attack, the tissues would be in a condition more nearly normal than if the case had been treated without the adoption of such measures.

THE PRESIDENT remarked that in advocating the administration of the hydrocarbons (and particularly the fixed hydrocarbons) from a physiological point of view, Dr. Flint seemed to forget that introducing these substances into the intestinal canal did not necessarily introduce them into the tissues. The trouble would be, that the fuel would lie inert in the intestinal canal and be discharged inert from it. He had presupposed normal digestion; while the fact was that, in typhoid fever digestion, assimilation and nutrition were very seriously impaired, and hence this fuel would not be acted on at all. He believed, therefore, that it would not be possible to carry out practically the theoretical ideas which Dr. Flint had advanced on this subject.

DR. E. G. JANEWAY said that he was afraid that an erroneous impression might be received from some of the statistics which Dr. Peabody had given in support of the treatment by refrigeration. In all such statistics the circumstances under which patients were admitted to the hospitals ought to be understood. Thus, during the late war many patients were carried for a long distance at a critical period of the disease, it being no uncommon thing to bring them all the way from Virginia to New York. At present, at the New York hospitals, patients who had had little or no attention before, were frequently brought in at a late period of the disease, when the chances were all against them. Another point worthy of note, was that Liebermeister and some others left out of their statistics all mention of the ages of the patients. The age made a very great difference in the mortality; since among the young the results were almost always good, while among the old, and even in all those over twenty years old, the reverse of this was likely to be true. In the hospital in New York which had been quoted by Dr. Peabody as having the smallest mortality, the favorable result was due principally to the fact that a considerable number of children with the disease had been treated in that institution. In the statistics of military hospitals the matter of age was not so important; but even in these it was necessary to be very guarded, because it was highly desirable to know all the concurring circumstances. During the war, patients were frequently transported for long distances in the second and third periods, when in private practice the patient would not be permitted to make the slightest exertion.

He had nothing to say against the antipyretic treatment of typhoid fever; but at the same time, he believed that very favorable results were often obtained under what was known as the expectant plan. At an outbreak at the deaf and dumb asylum a number of years ago, when the antipyretic treatment was unknown, he had treated fifty cases, with only two deaths; a mortality of four per cent. In another institution a similar good result was obtained, and he believed it was mainly due to the fact that the patients were young subjects. In Europe the authorities almost invariably left out from their statistics all those patients who died within a few hours after their admission to the hospital; which left the statistics of hospitals in this country (where such was not the practice) at a considerable disadvantage. For himself, he was a believer in the antipyretic treatment; but thought that the cold water should be used with special reference to the circumstances and character of the case. In the case of one young lady under his care, even cold sponging rendered her blue to the second phalanx of the fingers; and here he had resorted to the water-coil. Its action had not been very satisfactory, but it was the best that he could do under the circumstances, and the patient recovered; although she might perhaps have done so had no antipyretic treatment been used.

In regard to the matter of diet, he thought that more care ought to be used. One young man that he knew of, who was completely convalescent, and who had not been allowed to sit up at all until a week after all fever had subsided, at the end of a month from the time when the fever left, ate a quantity of nuts with some hard German bread. Within twenty-four hours there was probable perforation of the intestines, followed by peritonitis; showing that an atonic ulcer had probably still remained in the bowel. In regard to the eating of meat, however, considerable latitude might be allowed, and some time ago a Kentucky physician advised a meat diet all through the course of the disease. But still, while there was any doubt about the matter, it was advisable to adhere to a very careful diet. In the division of Bellevue Hospital to which he, as well as Prof. Flint, was attached, systematic refrigeration by cold water had been practised for several years.

DR. AUSTIN FLINT, SR., said that the Association was certainly to be congratulated in having presented to it two such admirable papers on typhoid fever as those of Dr. Janeway and Dr. Peabody. In regard to the views expressed in the latter, he differed from the writer in only one point, and that not a very important one. This was in regard to the value of cold sponging. His observation had led him to believe that sponging, if properly carried out, was a very efficient means of reducing temperature; but it was essential that it should be very thoroughly performed. Like Dr. Peabody, he had formerly had a portable bath-tub fitted up for use in the hospital wards, but he had found the bathing a very inconvenient method, and his experience went to show that all the advantages of the full bath could be obtained in other ways more easily followed out. In any case when sponging did not answer the purpose, he was in the habit of using the cold pack, wrapping the patient in a sheet and then sprinkling cold water over it; and for several years he had practised this method with advantage. He had therefore dispensed with the cumbersome bath-tub. He agreed with Dr. Peabody in the opinion that solid food should be given at a comparatively early period, and thought that it was a good rule to let the patient have it as soon as he himself desired it. It had been claimed that iodine and calomel cut short or cured typhoid fever; but he did not believe that as yet we had any specific for this disease, and until one had been discovered, it was necessary to treat

every case in accordance with the special character of the symptoms present. In regard to the administration of alcohol, he had passed through three phases of opinion on the matter. When he first began the practice of medicine no alcohol whatever was allowed, and the patient was starved as far as possible. Later, there came a revulsion of feeling in regard to it, and it was employed to excess; while at the present time there seemed to be a tendency, he thought, not to appreciate the very great advantages of the free use of alcohol in appropriate cases.

Dr. Peabody said that besides the objection to the suggestion of Dr. Flint, Jr., mentioned by Dr. Detmold, there was an additional one, viz., the difficulty of getting the patient to take the kind of food recommended. It was well known how hard it was to get typhoid fever patients to take a sufficient quantity of nourishment under any circumstances, and he was positively certain that they would object very strongly to taking sweet or greasy articles. In regard to Dr. Janeway's criticism upon European statistics, as regards the age of patients and the stage of the disease when treatment was commenced, he thought that, as a rule, the same would apply also to hospital statistics in this country, where these facts were as little determined as abroad. As to the exigencies of war causing a higher rate of mortality, the death-rate from typhoid fever among the white troops the year after the late war amounted to forty-nine per cent. As to the efficacy of cold sponging and the cold pack, he wished to say that, paradoxical as it might appear, he agreed with Professor Flint. When the sponging was thoroughly carried out, he believed that it was efficient; but the trouble was that, as a rule, it was *not* properly performed. In the special case to which he had referred there was a trained nurse who was considered properly qualified for the position in all particulars, and yet the temperature had remained unaffected. He had, therefore, urged the use of the full cold bath as the most efficient means of reducing temperature in the average case of typhoid fever.

THE CORRECTION OF DEFORMITIES BY MODIFICATIONS OF THE THICKNESS OF THE SOLE OF THE SHOE.

The President made some remarks, illustrated by diagrams on the blackboard, on the correction of certain deformities in the young by the simple device of thickening the inside or outside edge of the sole of the shoe, as required. In weak ankles, which were exceedingly common among girls, owing to the breadth of the pelvis, which gave a tendency toward knock-knee, there was always a protrusion of the internal malleolus. This was ordinarily treated by placing a certain amount of stiffening on the inner side of the shoe, and, this failing, by the use of iron splints. The simplest and best way of correcting the deformity, however, was by making the inner side of the sole thicker than the outer, which had the effect of lifting the weight off of that portion of the skeleton. The same method answered for the correction of knock-knee, but when the child was bow-legged, the thickening was to be placed on the outer instead of the inner side of the sole. If one leg was shorter than the other, there would inevitably result more or less tilting of the pelvis; which had the effect in time of producing lateral curvature of the spine, with its secondary or compensating curvature. This could easily be remedied, when taken in time, by making the sole of the shoe for the foot of the shorter limb sufficiently thick to bring the transverse axis of the pelvis at right angles to the lower extremities. Dr. Detmold also explained his method of treating flat-foot (which was common in young girls who were poorly nourished and who were obliged to remain in a standing position much of the time), as well as elevation of one shoulder above the other. In five out of every nine young girls, he thought, the right shoulder was a little higher than the left.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, March 11, 1884.

The President, R. F. Weir, M.D., in the Chair.

TRAUMATIC RUPTURE OF THE TRACHEA.

Dr. J. L. Little presented a trachea removed from a man sixty years of age, who died in St. Vincent's Hospital, having been struck in the neck and upper part of the sternum on Saturday last, by one of the shafts of a truck. When he first saw the case, five hours after the injury, he found the patient emphysematous from the head to the lower part of the abdomen. There was considerable ecchymosis over the sternum. No difficulty in breathing. No cough or pain on pressure over the upper part of the sternum and trachea. Had had slight expectoration of blood before entering the hospital. The emphysema was greater over the chest than elsewhere, and less about the neck. Injury of the trachea was suspected. The patient was anæsthetized and a careful examination was made over the trachea and larynx, but no injury of these parts could be detected, and, as there were no symptoms of suffocation, it was thought best not to perform tracheotomy. He, however, gradually sank and died this morning, sixty hours after the injury. There was considerable cyanosis during the last twelve hours, but no symptoms of suffocation.

The autopsy showed a complete separation of the fourth and fifth rings of the trachea, with signs of recent inflammation and hemorrhage in the surrounding tissues. Double hypostatic pneumonia and pleurisy also existed.

FLOATING CARTILAGE IN THE KNEE-JOINT; REMOVAL.

Dr. Little also presented a specimen of floating cartilage, which he removed from the knee-joint of a patient who came under observation three weeks ago, having suffered from a slight pain in the knee for ten years. About six weeks ago, he noticed symptoms for the first time, indicating the presence of a loose cartilage, and on examination a movable body was discovered which was quite prominent. On the 28th of February last, Dr. Little removed it under strict antiseptic precautions.

The operation was performed as follows: A bandage was applied from the leg to a point just above the patella, so as to keep the loose cartilage in the upper part of the joint. It was then fixed at a point on the outer side of the joint by a strong acupressure needle passed through the tissues. An incision was made, and it was removed with a pair of bullet-forceps. The edges of the wound were brought together by two catgut sutures. The synovial membrane was not included in

the sutures. A compress of iodoform gauze and a full Lister dressing were applied.

Patient did well until the morning of the fourth day, when he had a chill and a sudden rise of temperature (102°). On removing the sutures, about half an ounce of pus escaped from the wound. The synovial cavity was found to be slightly distended, but no fluid could be pressed from the joint through the wound. Believing that the collection of pus was external to the joint, he redressed it; in a few hours the temperature subsided, and in forty-eight hours the effusion disappeared from the joint, and the patient made a rapid recovery.

DR. W. T. BULL had removed three of these cartilages. In two cases he put in no sutures, and the result was satisfactory. In the third case he used sutures, and the man had a very troublesome effusion, which lasted for six months, coming and going. He employed catgut sutures, and they were introduced through the capsule.

DR. SANDS had performed, within the last six months, three operations upon the same patient; the right knee being operated upon twice, and the left knee once. In each case the operation was performed in the same way, the joint being directly incised, and the edges of the cutaneous wound being united by sutures after the removal of the floating cartilage. Bichloride solution was the antiseptic employed, and peat was used as a dressing. In all the cases primary union took place without rise of temperature, and without effusion into the joint.

DR. A. G. GERSTER had also had occasion to operate upon three patients, in two of whom there were three movable bodies, one of which could be proved to be chipped off from the tibia; the second was a smooth almond-shaped body, the origin of which could not be ascertained; the third he was obliged to manipulate for considerably, and it was found that several small bodies were attached by pedicle to the ligamentum alare near the inner margin of the patella. These growths had to be extirpated from their attachments, and it became necessary to tilt up the patella and expose its under surface for this purpose. In all three cases the joint was washed with a five per cent. carbolic solution, it being before the advent of the bichloride solution. In all of the cases a supporting suture was applied through the capsule, and after that skin stitches were introduced, and in every case a drainage-tube of small calibre was left in the joint for the purpose of removing as much effusion as might take place, but this tube was removed on the fourth day. In all the cases the dressings were antiseptic and recoveries were uninterrupted.

THE PRESIDENT had an instance brought to mind by Dr. Gerster's last case, that is, the presence of fatty growths in joints. Last autumn he cut into the knee-joint for the removal of a loose cartilage, situated on the inside of the patella, movable in various directions, but attached somewhere in the region of the patella, and about the size, as felt through the skin, of the end of his little finger. On reaching it, it was recognized as being not of the usual cartilage formation, but softer; and, subsequently, on microscopical examination it proved to be fibrous tissue with fat. It was analogous to the fatty growths which Barwell had described, and had removed successfully from the knee-joint; and Volkmann also speaks of similar troubles in the same joint. In his case considerable manipulation of the joint was resorted to in the removal of the foreign body, and although antiseptic precautions were used, the wound and the joint washed out with sublimate solution (1 to 5000), and a drainage-tube inserted, the case went to the bad, and suppuration of the joint and of the tissues about the articulation took place; threatening septicæmia developed, necessitating amputation of the thigh, which was done after Neuber's method, with rapid healing. The process of inflammation had, however, so destroyed the tissues of the joint that he was unable to demonstrate anything further concerning the connection which this peculiar formation had with the joint itself, although it was evidently a hypertrophy of the subpatellar fatty tissues.

He had, also, since met with one other case of this kind, but he did not operate upon it. He saw last week at his college clinic, a woman about fifty years of age, who had had symptoms of floating cartilage during the last twenty years. The body was quite large, and was situated at the inner and upper aspect of the joint, and from the symptoms and from the attacks of its catching between the articular surfaces, he assumed that it was attached by a somewhat long pedicle. The patient was unwilling to have an operation performed, because she suffered but little, and the permanent joint damage was not marked. The special interest in the case was the rather long time for such a difficulty to exist without serious impairment of the joint.

DR. GERSTER asked Dr. Little if he applied a posterior splint after his operation.

DR. LITTLE said that he had neglected to state that he applied a posterior splint after the operation, so that the joint was kept perfectly quiet.

THE PRESIDENT had employed a splint and also used firm compression, after opening the knee-joint.

DR. SANDS said that in his three cases the limb was placed, after the operation, upon a posterior splint, and the dressing was not removed for two weeks.

DR. BULL said that in all his cases he used the typical Lister dressing and a posterior splint.

DR. GERSTER said that he also applied a splint in all his cases.

EPITHELIOMA OF THE LARYNX.

DR. MCBURNEY presented a specimen with the following history: It was removed from a male patient, fifty-nine years of age, who first exhibited symptoms of disease four months ago, the first being the discovery of a small swelling in the right side of the neck beneath the angle of the jaw. It was not until the end of January that any dysphagia was noticed, but there was no dyspnœa. When he came under Dr. McBurney's observation in February, the man had a large tumor on the right side of the neck, extending from the angle of the jaw nearly to the clavicle. He was able to speak with quite a clear voice, complaining almost not at all of difficulty of swallowing, although at times of some difficulty in swallowing solid food. On examination with the laryngoscope, Dr. McBurney was able to see a large mass apparently filling the entire lumen of the larynx, and the appearance was such that he was unable to account for the excellent voice. He had no means of determining the extent of the growth, although its appearance indicated that it extended down the œsophagus. The patient died on Friday last. He swallowed

fairly well up to that time, although there had been steadily increasing dysphagia. The voice remained very good until death. The specimen showed that the true vocal cords were entirely unimpaired.

Dr. McBurney also presented the specimen removed from the neck, which was probably carcinomatous, although the microscopical examination had not been completed. The most interesting feature perhaps was the condition of the artery seen upon the back of the specimen, where, near its bifurcation, endarteritis obliterans was apparent, and the vessel just above was firmly attached to the tumor. There was no direct positive union of the two tumors, but he inferred that the laryngeal was the original growth, and that the tumor in the neck was secondary, and one which began in the lymphatic glands.

EPITHELIOMA OF THE CERVIX; EXTIRPATION OF THE ENTIRE UTERUS THROUGH THE VAGINA; RECOVERY.

Dr. W. T. Bull presented a uterus which was the seat of cancer, involving the greater part of the cervix. It was removed by the vaginal method on the 17th of February, 1883, from a patient forty-five years of age, who had had symptoms of uterine cancer one year previous to admission to the hospital. At the time of admission, the growth formed a large cauliflower excrescence at the upper part of the vagina, and apparently did not involve the body of the uterus. She had not received any treatment. The urine had a specific gravity of 1020, was acid, contained a little albumen and a few hyaline casts. The uterus was removed by Czerny's method without difficulty, although the operation was laborious and long from the care required to dissect the expanded cervix from the base of the bladder. The broad ligaments on either side were secured with two carbolized silk ligatures and cut between them. The peritoneal wound was loosely held together with four or five sutures. Just before the time the sutures were introduced, a mass of intestine or omentum could be seen at the bottom of the wound. In passing the sutures through the peritoneum, hemorrhage occurred from one of the broad ligaments, which was controlled by the hæmostatic forceps, and it was necessary to leave the instrument in position. The wounded surfaces were dusted lightly with iodoform, the vagina was packed with small iodoform peat bags, and the vulva covered with borated cotton. There was but slight reaction, and, at the end of five days the first dressing was made, and while there was more or less discharge, there was no evidence of decomposition whatever. At that time the hæmostatic forceps were removed. The further progress of the case was rapid; at the end of one month the patient was able to sit up, and soon afterward left the hospital. For eight months afterward the patient continued in very much better health than she had enjoyed for years previous to the operation, and believed herself to be cured. There remained, however, a small spot at the top of the vagina which was not disposed to heal, although her general condition was quite good. About nine months after the operation there appeared a hard nodule on the posterior vaginal wall, which was removed with the curette, together with the small spot previously noticed. For a month afterwards the condition of the parts remained unchanged. From the tenth month after the first operation up to the present time, the patient's health has slowly declined, and now, nearly thirteen months after the first operation, she is worse than at the time she first entered the hospital. She has a pelvic tumor about the size of a child's head, and has the distressing abdominal symptoms which usually accompany this condition, yet there has been no offensive discharge from the vagina, nor hemorrhage.

In two other cases he had attempted the same operation, and, being unable to get the uterus out with safety, had simply contented himself with the effort to remove as much as possible after dissecting the tumor from the bladder and rectum, without opening the peritoneal cavity. Both patients recovered rapidly from the operation, although in one the cul-de-sac of Douglas was accidentally opened. He thought the operations had been of much benefit to the patient, especially with reference to getting rid of the offensive discharges and hemorrhages which almost invariably accompany cancer of the uterus. One woman, who had several hemorrhages before the operation, went six months without any bleeding or abundant discharge, and died a year afterwards. The other had been operated on but a few weeks ago.

Dr. Lange said that he had presented to the Society one patient from whom he had extirpated the uterus totally for sarcoma two years ago. About six weeks ago he saw the patient, and she was apparently entirely healthy. In two other cases in which he had performed the supravaginal amputation—one for a very large myosarcoma and the other for a large fibroma—the patients were still quite well; one sixteen months after the operation, and the other nine or ten months after the operation.

SARCOMA OF KIDNEY.

Dr. J. L. Little presented a specimen which he removed at St. Luke's Hospital by operation on September 11, 1883, from a girl four years old. According to the mother's statement the child's abdomen had been swollen and hard from birth. One month previous to admission this enlargement began to increase rapidly. On examination the abdomen was found to be greatly distended, very tense and fluctuating, and the subcutaneous veins over the surface were enlarged. The enlargement of the abdomen was so great that it prevented the child from walking or standing. There was marked dulness on percussion over the right side of the abdomen extending several inches beyond the median line. From this point it was tympanitic; a distinct tumor could be felt occupying the entire region of dulness, extending upwards to the margin of the ribs. There was no œdema of the feet. The urine was normal, and the child's general health was good.

On September 15th the tumor was aspirated, and about eight ounces of dark-red fluid were removed. On examination it was found to contain blood globules, but no further evidence as to the character of the disease was revealed.

A consultation was held, which resulted in a diagnosis of a cyst, probably connected with the kidney—hydro-nephrosis; and an explorative incision was advised.

On September 25, Dr. Little performed the following operation under strict antiseptic precautions: He opened the abdominal cavity by an incision two or three inches

long between the umbilicus and pubis, which was subsequently enlarged. A considerable quantity of fluid at once made its escape from the abdominal cavity. The tumor was found situated beneath the posterior layer of the peritoneum, extending from the pelvis up to the borders of the ninth or tenth rib, and overlapping the spinal column. A large trocar was passed into the most prominent part and nearly two quarts of a dark-colored fluid were evacuated. It was then found that the upper portion of the tumor was solid. The peritoneum covering the tumor was then opened and the growth carefully enucleated. Its upper part was found to be in such intimate connection with the kidney that it was necessary to remove that organ. A ligature was passed around the renal vessels and the whole mass was removed. The hemorrhage during the operation was not great, and was readily controlled. The peritoneum was closed by catgut, and the abdominal wound by silver wire sutures, and Lister's dressings were applied. The condition of the patient during the later part of the operation was very feeble, and, although every means to bring on a reaction were used, she died from shock about half an hour after the completion of the operation.

Microscopical examination of the tumor was made by Dr. Frank Ferguson:

Small round-celled sarcoma with cysts. The tumor arises from the anterior aspect of the lower end of the right kidney. Its shape is spheroidal, and it measures six inches in diameter. It is surrounded by a fibrous capsule, rich in small round and spindle-form elements, and continuous with the capsule of the kidney. There are numerous cysts of various sizes throughout the tumor, into some of which hemorrhage has occurred; but, as a rule, their contents are a clear serum-like fluid, rich in albumen, and a few of the small round cells of which the tumor is composed. In these cysts are also found kidney tubules and glomeruli. Kidney structure is also seen throughout the tumor. The cells which compose the tumor are supported by a delicate framework of fibrillated material; and the entire tumor is rich in its vascular supply. The kidney is slightly larger than in subjects of this age, and, on microscopic examination, normal in structure beyond the line of invasion of the morbid growth.

Stated Meeting, March 25, 1887.

THE VICE-PRESIDENT, CHARLES MCBURNEY, M.D., IN THE CHAIR.

LARGE TUMOR OF THE THIGH.

DR. JAMES L. LITTLE presented a patient, a man, forty-eight years of age, whose horse reared and fell upon him while in the army, twenty years ago, the pommel of the saddle inflicting a contusion on the inner aspect and about the middle part of the left thigh. An inflammatory swelling followed, which lasted from the twenty-third of June until winter, and then disappeared entirely. Five years afterward, a swelling occurred up and down the thigh, along the site of the original injury, which gradually increased until it reached the present size. The circumference of the right thigh was nineteen inches; the circumference of the left thigh around the tumor was thirty-one and a half inches. It was a painless, movable swelling, which Dr. Little regarded as a lipoma, and also thought it was a proper case for operation.

DR. A. G. GERSTER inquired whether the tumor had been punctured, and the patient replied that only small needles had been introduced, but the aspirator had not been used. Dr. Gerster continued, and recalled the case of a tumor of this kind, situated in the same locality, that came under his observation at Mt. Sinai Hospital, four years ago, in which the diagnosis of cyst was made after puncture, but it finally proved to be an old abscess.

It seemed to him that the tumor in Dr. Little's case was pretty well outlined by the entire extent of the adductor muscles. He was unable to find any lobulation, such as usually exists in lipoma, and he believed that in order to make the diagnosis clear it would be very important to make puncture. The contents of the tumor to which he referred contained an enormous quantity of cholesterine crystals. It had occupied five years in developing; its growth was very gradual, and there was an early history of very severe pain in the thigh. Excision of the tumor was attempted, and when he reached what was supposed to be the capsule, it was found to be simply a pyogenic membrane, closely attached to the inner surface of the adductor muscles. A very large quantity of peculiar shining liquid was evacuated, which contained cholesterine crystals and detritus. Samples of the fluid removed by puncture prior to the operation were submitted to two microscopists, one of whom diagnosed undoubted ovarian tumor. After having evacuated the contents, he found floating in the cavity a small solid body, which was found to be a portion of the cortical substance of the femur from the vicinity of the small trochanter, and examination of that locality revealed a slight depression. He concluded that a cortical necrosis with myelitis took place five or six years ago, and that a sequestrum was released and became the point around which an abscess formed, and that the original site of the osteomyelitis had healed, and the cold abscess continued to exist with its pyogenic membrane, which gradually increased to the size of the apparent growth. The man recovered entirely.

DR. LITTLE said that he operated on a tumor of the thigh, similar to the one described by Dr. Gerster, in February last, which was very large, and which moved with every movement of the muscles. Upon tapping it, a shining, yellow fluid was removed, which was filled with cholesterine crystals. The sac was laid open and the inner surface of the cyst was found to be covered with granulating material, which was scraped off, and the case did well. It was supposed to be the result of an old abscess. Antiseptic precautions were used.

DR. T. M. MARKOE said that from the feel of the growth he should doubt whether it was a cystic tumor. He found that it was beneath the fascia lata, and that it was continuous with the adductor tendons below, which passed internal to the tumor and formed a part of its internal surface: that fact alone would induce him to doubt whether it was a fatty tumor. Another feature which led him to doubt as to its being a fatty tumor was the fact that no corrugation of the surface was seen when it was pressed together—a feature almost characteristic of lipomatous growths. He was inclined to regard it as a form of sarcoma.

DR. GERSTER thought that the length of time which

the tumor had existed spoke against the sarcomatous character of the growth, and there was also a notable absence of any systemic disturbance.

Dr. Little remarked that he had removed one fatty tumor much larger than this one, situated in the same locality.

Dr. Briddon said that that some ten or fifteen years ago he saw a tumor like this in the gluteal region, which was influenced by some of the muscles arising from the pelvis and inserted into the femur. In that case he used the aspirator, as he thought, for the first time it was used for this purpose in this city, and the results were negative. Supposing it to be a fatty tumor, he made a long incision for its removal, but it turned out to be an abscess with a very thick covering, which prevented fluctuation from being detected.

Dr. Markoe said that a form of tumor had been described by Paget as fibro-cellular, the histological type of which was loose, areolar cellular tissue infiltrated with serum, etc., which may attain an enormous size and yet possess none of the elements of malignancy. He thought the tumor in Dr. Little's case corresponded more nearly to that form of growth than to any other.

CORRESPONDENCE.

LIME INHALATIONS IN DIPHTHERIA.

To the Editor of The Medical News.

Sir: Having seen lime inhalations used on several occasions, both in diphtheria and membranous croup, and being convinced of their value, I was surprised by the remark of Dr. Kolipinski, in the number of The Medical News for March 22, that the value of the treatment depended upon the vapor of hot water.

To prove the correctness of this statement I made the following experiment: A wide-mouthed glass bottle, containing unslaked lime and a sufficient quantity of water, was rapidly corked and connected by a glass tube, in the usual manner, with a beaker containing a solution of carbonate of sodium. The vapor arising from the slaking lime was passed through the solution of the alkaline carbonate, but no white precipitate was produced, proving the absence of lime. The same experiment was repeated, a solution of oxalic acid being substituted for that of the carbonate, but no precipitate of oxalate of lime formed.

It may be claimed by some that lime is carried along by the vapor in the form of a powder, and thus comes in contact with the exudations of the fauces and air-passages, but the glass tubes used in these experiments were of good size, and any particles of lime which might have been carried along, mechanically, with the vapor, could readily have passed through the tube, but no sediment of any kind was noticed in the solution either of the carbonate or the acid.

The fact, however, remains that the vapor of hot water is of great benefit in the treatment of diphtheria and membranous crup, but some more convenient ways of generating steam for inhalation may often be at hand than the method of producing it by the slaking of lime.

Respectfully,

Bernard Persh, M.D.,
Hospital Steward, U. S. A.

The Frankford Arsenal, Pa.,
March 26, 1884.

THE LOCAL TREATMENT OF ERYSIPELAS.

To the Editor of The Medical News.

Sir: The March number of the *College and Clinical Record* contains the report of a clinic of Professor Bartholow, in which, with reference to the local treatment of facial erysipelas, and the various applications that have been used, he says: "We cannot, as a rule, prevent the spread of the disease by the remedies mentioned. We cannot prevent or limit, by such measures, the constitutional condition." For several years I have used a mixture of salicylic acid (Squibb) one drachm to glycerine and rose-water each half an ounce, applied with a camel's-hair pencil frequently and thoroughly over the affected parts, taking care to cover well beyond the line of demarcation. I have a record of quite a number of cases treated in this way, and in every instance the first or second application was sufficient to check the spread of the disease. The only internal treatment used was some saline water or mixture.

Yours very truly,

H. M. Shallenberger, M.D.

Rochester, Pa., March 28, 1884.

THE DISCOVERER OF THE MICROCOCCUS OF SWINE-PLAGUE.

To the Editor of The Medical News.

Sir: In your number of March 15th, attention is called to an article by Dr. D. E. Salmon, in *Science*, in which it is claimed that Pasteur was wrong in acknowledging Dr. H. I. Detmers as the first discoverer of the swine-plague parasites. Dr. Salmon's paper in *Science* does such injustice to the merits of Dr. Detmers, that it seems incumbent upon his friends to vindicate the latter investigator's title of priority.

Dr. Klein, of London, described, in his first article, micrococci in the bodies of dead pigs, the description of which agrees with the observations of later authors. But he did not prove these micro-organisms to be the cause of the disease. This proof was furnished for the first time, by Detmers, in 1878, in the Special Report of the United States Commissioner of Agriculture (No. 12, p. 37, etc., and Annual Report, 1878, p. 347). He found invariably a specific kind of bacteria in the fluids and diseased tissues of the animals just killed. He obtained growing cultures of these bacteria in sterilized fluids out of the body, and, by inoculation with traces of these cultures, he reproduced the typical hog-cholera in previously healthy pigs. Since all precautions necessary to render such experiments faultless were fully carried out, no flaw can be detected in Detmers's demonstration of the bacterial origin of the disease. He did, however, commit a mistake in the description of, and name given to, the parasites. He termed them "moniliform bacilli;" for, with his insufficient lenses, they appeared as serrated rods. Better instruments resolved them subsequently into diplococci and coccus-chains. The error in the botanical description of the bacteria was hence corrected in the following year (Special Report No. 22, p. 60, and Annual Report, 1879, p. 412). The description of the characteristic mode of grouping, and the drawings of the parasites in these first two reports, as well as in the later one of 1880, show that Dr. Detmers really dealt with the same micro-organisms in all these instances.

Since Dr. Salmon did not mention the existence of swine-plague bacteria in any of his articles prior to December, 1880 (Special Report, No. 34), and since in this first account of his, no results are brought forth in advance of what Detmers had discovered one or two years previously, the injustice to Dr. Detmers is manifest.

Respectfully yours,

H. GRADLE, M.D.

CHICAGO, March 20, 1884

NEWS ITEMS.

CHICAGO.

(From our Special Correspondent.)

THE COMMENCEMENT OF THE CHICAGO MEDICAL COLLEGE took place in the Grand Opera House on March 25th. The graduating class consisted of thirty-nine members.

The Dean, Dr. N. S. Davis, made some remarks in view of the twenty-fifth anniversary of the institution. He vindicated for it the honor of having been the first American medical college that introduced the graded system of instruction.

From its start this College was the only one, for twelve years, that did not repeat to the same class of students the same annual course of lectures, both elementary and advanced. Twelve years later Harvard College imitated this system, and was then followed by the University of Pennsylvania and a host of other institutions of medical learning.

The college, beginning twenty-five years ago with a modest class of thirty students and nine graduates, has since had 2773 matriculants and sent out 863 graduates.

THE SIXTH REPORT OF THE GERMAN CHOLERA COMMISSION.—The following is the text of the sixth and concluding report of the German Cholera Commission :

The question whether the bacilli found in the bowel of cholera patients are parasites belonging exclusively to cholera, which was left undecided in my last report, can now be looked upon as settled.

At first, on account of the varying pathological appearances presented by the bowel in cholera, and on account of the large number of bacteria always found therein, it was extraordinarily difficult to discover the truth. In most cases death does not occur at the height of the cholera process, but in the reaction-period which follows immediately after, and in which such considerable changes take place in the bowel and its contents, that it is impossible from such cases alone to obtain a clear idea of the cholera process. It is not until one has had the opportunity of examining a number of uncomplicated cases, and of comparing with them cases recently attacked, that one can succeed in obtaining a true insight into the pathological relations of cholera. For this reason it was thought right to exercise the greatest caution in interpreting the discoveries made with regard to bacteria in cholera, and to reserve a definite judgment on their causal relation to the disease until we had fully made up our minds on the subject.

In the last report I was able to state that peculiar characters had been found in the bacilli tenanting the cholera bowel, by which they could be distinguished with certainty from other bacteria. Of these features the following are the most characteristic: The bacilli are not quite like a straight line as other bacilli, but a little curved, like a comma. This curving may even be so marked that the bacilli assume almost a semicircular outline. In pure cultivations these curved bacilli often give rise to S-shaped forms, and to wavy lines of varying length, the former of which correspond to two individuals, and the latter to a considerable number of the cholera bacilli, which have remained in connection as they continued to proliferate. They possess, moreover, movements which are very active, and may be best observed in a drop of the cultivation solution suspended from a covering glass. In such a case one sees the bacilli swim across the field of the microscope with great rapidity in all directions.

Their behavior on gelatine is peculiarly characteristic. They form colorless colonies which, at first, look as if they were composed of tiny glittering fragments of glass. Gradually these colonies cause the gelatine to melt, and then spread themselves out to a moderate extent. In gelatine cultivations, therefore, this peculiar appearance enables one to distinguish them from other colonies of bacteria with great certainty, and to isolate them from the latter with ease. They can, moreover, be demonstrated with comparative certainty by cultivation on concave slides, as they always betake themselves to the margin of the drop of cultivation liquid, and can there be recognized by their peculiar movements, and, after staining with aniline, by their comma-like shape.

So far, twenty-two cholera cadavers and seventeen cholera patients have come under examination in Calcutta. All these cases were examined for the presence of the specific bacteria, both by the help of gelatine cultivations and also by microscopical preparations, and, in most cases, by cultivation on concave slides; the comma-like bacilli were found in all, without an exception.

This result, taken together with that obtained in Egypt, justifies the conclusion that this kind of bacterium uniformly occurs in the cholera bowel.

With the view of controlling the result, there were examined in exactly the same manner twenty-eight other cadavers (including eleven dead from dysentery), and also the evacuations of a case of simple diarrhœa, of dysentery, and of a healthy patient who had recovered from cholera, besides various animals, both healthy ones and others which had died of ulceration of the bowel and pneumonia; and lastly, we also examined water contaminated with putrid masses. In not a single case, however, did we succeed in demonstrating the cholera bacilli, either in the stomach or bowel of the cadavers, or in the evacuations, or in the other fluids, rich as they were in bacteria. As a disease process very similar to cholera is produced by poisoning with arsenic, an animal, so poisoned, was examined to see if the comma-bacilli were present in the digestive organs, but in this case also the result was negative.

From these results the further conclusion may be drawn, that the comma-like bacilli are altogether peculiar to cholera.

As to the relation of these bacteria to cholera, I have already explained, in a previous report, that either this specific kind of bacterium is specially favored in its growth by the cholera process, and hence combined in

such a striking way with cholera: or that the bacteria are the cause of cholera, and the disease only arises when these specific organisms have found their way into the bowel. The first hypothesis cannot be accepted, for the following reasons: It must be assumed that a man when he sickens with cholera has already this kind of bacterium in his alimentary canal, and further, inasmuch as these peculiar bacteria were found without exception in a comparatively large number of cases both in Egypt and in India, two widely separated countries, it follows that every man must be tenanted by them. This, however, cannot be the case, for, as already stated, the comma-like bacilli have never been found except in cases of cholera.

Even in bowel affections, such as dysentery and enteric catarrh, which so often pass on into cholera, they were absent. It is also to be remarked, that, if these bacteria had been so regularly present in human bodies, they certainly would have been previously observed at some time or other, which is not the case.

As, therefore, the growth of these bacteria in the bowel cannot be produced by cholera, there remains only the second hypothesis, that they are the cause of cholera. That this is indeed the case, a number of other facts attest in an unmistakable manner; above all, their behavior during the disease process. They confine themselves to the organ which is the seat of the disease—the bowel. In vomit they have only been twice recognized, and in both cases both the appearance and the alkaline reaction of the vomited fluid have proved that bowel contents, and with them the bacteria, have obtained access to the stomach. In the bowel itself they conduct themselves as follows: In the first evacuations of patients, and as long as these retain their fecal character, only very few cholera bacilli are found; the subsequent watery, inodorous evacuations, however, contain them in great numbers, all the other forms of bacteria almost completely disappearing from that moment, so that at this stage of the disease, the cholera bacilli form in the bowel almost a pure cultivation. As soon, however, as the attack of cholera subsides and the evacuations again become fecal, the comma-like bacteria gradually disappear from the evacuations, and when the disease has completely passed over, are no more to be found. What is found in cholera cadavers is exactly similar. No cholera bacilli are met with in the stomach. The bowel contains them in varying numbers, according as death has occurred during the cholera attack, or after it. In the most recent cases—in which the bowel presents a uniform bright-red color, the mucous membrane is still free from extravasations of blood, and the contents of the bowel consist of a whitish, inodorous fluid—the cholera bacilli are found in the bowel in enormous quantities, and almost pure. Their distribution corresponds quite accurately to the degree and extension of the inflammatory irritation of the mucous membrane, while in the upper part of the bowel they are not usually so numerous, but increase toward the lower portion of the small intestine. If, on the other hand, death occurs later on, we find the signs of a considerable reaction in the bowel. The mucous membrane is of a dark color; in the lower part of the small intestine it is covered with blood extravasations, and its most superficial layers have often ulcerated away. The contents of the bowel are in this case more or less blood-stained, and, in consequence of renewed development of putrefactive bacteria, are putrid in character and offensive. The cholera bacteria in this stage do not reappear in the contents of the bowel, but they are still present in considerable numbers for some time longer in the tubular glands, and often also in the neighboring tissues, a fact to which attention was first called by the appearance of these peculiar bacteria in the bowel of the Egyptian cholera cases. They are entirely absent only in those cases which die from some sequela, when the cholera attack has quite passed off.

The cholera bacteria behave, then, exactly like all other pathogenic bacteria. They appear exclusively in their own peculiar illness, their first appearance coinciding with the commencement of the disease; they increase in number proportionally to the advance of the disease; and disappear with its decline. Their seat corresponds in like manner with the extension of the disease-process, and their number is, at the height of the disease, so considerable as to be quite sufficient to explain their destructive influence upon the mucous membrane of the bowel.

It would certainly be very desirable to succeed in producing in animals artificially, with these bacteria, a disease analogous to cholera, so that their causal relation to cholera might receive ocular demonstration. In this, however, we have not yet succeeded, and it is even questionable whether success will ever be attained in this direction, because, according to all appearance, animals are insusceptible of the cholera infection. If any species of animal whatever could take the cholera, it would surely have been observed in a reliable manner in Bengal, where the infective material of cholera is met with throughout the year and throughout the land. All inquiries, however, directed to this point have met with a negative result.

Nevertheless, the demonstrative force of the facts given above is not weakened by the failure of the experiments on animals. The same phenomenon meets us, also, in other infective diseases; for instance, in enteric fever and in leprosy, two diseases in which specific bacteria also occur, but which hitherto no one has succeeded in conveying to animals; and yet the mode of appearance of the bacteria in these diseases is such, that they must undoubtedly be regarded as the cause of the disease. The same is true also of the cholera bacteria.

Moreover, the further study of the cholera bacteria has enabled us to recognize several other characteristics which are all in harmony with what is known about the etiology of cholera, and thus must be regarded as an additional confirmation of the correctness of the hypothesis that the bacilli are the cause of cholera.

The most remarkable circumstance relative to this, is the fact that it has been repeatedly observed that when the linen of cholera patients, after being soiled by their dejections, has been kept for twenty-four hours in a moist state, the cholera bacilli are found to have multiplied in a most extraordinary manner. This will account for the well-known fact, that the linen of cholera patients has so often infected those persons who have to do with it. Attention having been called to this observation, further experiments were made, and it was found that the same phenomenon occurred whenever cholera dejections, or the intestinal contents of cholera cadavers, were spread upon linen or blotting paper, kept moist,

and especially upon the surface of damp soil. In twenty-four hours the thin film of mucus was invariably found to be completely converted into a thick mass of cholera bacilli.

Another very important quality of cholera bacteria is that they die off after drying more quickly than almost any other form of bacteria. As a rule, even after three hours' drying, every vestige of life has disappeared.

Another peculiarity is that they will only grow in alkaline cultivation-fluids, even a very small quantity of free acids, which would have no tangible effect on the growth of other bacteria, delaying their development in a striking manner.

In the healthy stomach they perish, which will account for the fact that over and over again it has been found impossible to detect them in the stomach or intestines of animals, which had been fed for a considerable period on cholera bacilli, and then killed. This last characteristic, together with their slight power of resisting drying, explains what daily experience teaches us, viz., that infection so seldom follows upon direct contact with cholera patients or their ejecta. Evidently other peculiar circumstances must be present, in order that the bacilli may be placed in a position to pass through the stomach, and then to produce the cholera processes in the bowel. Possibly, bacilli can pass uninjured through the stomach, when digestion is disturbed, a hypothesis supported by what is seen in all cholera epidemics, and uniformly noted here in India, viz., that those men are especially liable to cholera who are suffering from indigestion. Perhaps, however, some special condition under which these bacteria may occur, and which would be analogous to the persistent condition (*Dauerzustand*) of other bacteria, may enable the cholera bacteria to pass the stomach uninjured.

It is not probable, it is true, that this change consists in the production of persistent spores, for such spores have been found to retain life for months and even years, whereas the cholera poison does not remain active longer than about three to four weeks. Nevertheless, it is quite conceivable, that some other form of persistent condition exists in which the bacilli can remain for some weeks alive in a dried state, and in which they are also in a position to resist the destructive influence of gastric digestion.

The conversion into such a state would then correspond to what Pettenkofer has described as the maturing of the infective matter of cholera. Hitherto we have not succeeded in discovering such a persistent state on the part of the cholera bacilli.—*Medical Times and Gazette*, March 22, 1884.

THE GARFIELD MEMORIAL HOSPITAL.—The staff of the Garfield Memorial Hospital at Washington has been constituted as follows:

Consulting Surgeons.—Drs. Fred. May and N. S. Lincoln.

Consulting Physicians.—Drs. W. W. Johnston, J. Taber Johnson, and A. Y. P. Garnett.

Attending Surgeons.—Drs. C. E. Hagner and J. H. W. Lovejoy.

Ophthalmologist and Otologist.—Dr. Swan M. Burnett.

The Board of Directors hopes to be able to open the hospital in May.

JEFFERSON MEDICAL COLLEGE.—The Annual Commencement of the Jefferson Medical College was held on Saturday March 29th. Two hundred and fifteen graduates received the degree of Doctor in Medicine.

MEMPHIS HOSPITAL MEDICAL COLLEGE.—The annual commencement of the Memphis Hospital Medical College took place on February 29. Diplomas of Doctor in Medicine were conferred upon twenty-three graduates.

THE LITTLE ROCK MEDICAL COLLEGE.—The annual commencement of this College was held on March 3. The degree of M.D. was conferred upon thirteen graduates.

THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA.—The annual session of this Society will be held in the city of Selma on Tuesday, April 8, and continue four days.

MEDICAL SOCIETY OF THE STATE OF TENNESSEE.—The fifty-first annual meeting of this Society will be held at Chattanooga, on Tuesday, April 8.

RUMFORD CHEMICAL WORKS.—The United States Circuit Court in Maryland has decreed a perpetual injunction against certain parties, restraining them from imitating the labels of the Horsford's Rumford Yeast Powder, and also from using their old bottles.

RITTER VON SCHMERLING'S JUBILEE.—On Monday, March 10th, the fiftieth Doctorate Jubilee of DR. RAINER RITTER VON SCHMERLING was celebrated in Vienna. Congratulatory addresses were made by prominent members of the Vienna Faculty, and by representatives from various scientific and social societies.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending March 22, 1884, indicate that intermittent fever, scarlet fever, and remittent fever have increased, and that inflammation of the kidney and neuralgia have decreased in area of prevalence.

Including reports by regular observers and others, diphtheria was reported present at fifteen places, scarlet fever at twenty-three places, and measles at seven places.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 25 TO MARCH 31, 1884.

HAMMOND, JOHN F., *Colonel and Surgeon*, now in New York City on sick leave of absence, will, after the expiration of his sick leave, await orders in that city.—*Par. 8, S. O. 70, A. G. O.*, March 26, 1884.

MEARNS, EDGAR A., *First Lieutenant and Assistant Surgeon*. —Assigned to duty at Fort Verde, A. T.—*Par. 1, S. O. 22, Headquarters Department of Arizona*, March 19, 1884.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

ORIGINAL LECTURES.

A COURSE OF LECTURES ON DERMATOLOGY.

Delivered at the University of Pennsylvania during the Session of 1883–1884.

BY LOUIS A. DUHRING, M.D.,
PROFESSOR OF DERMATOLOGY IN THE UNIVERSITY

(Reported by Henry Wile, M.D.)

LECTURE III.

HERPES, MILIARIA, POMPHOLYX, PEMPHIGUS, LICHEN, PRURIGO, ACNE, ACNE ROSACEA.

HERPES may be described as an acute inflammatory disease, consisting of one or of several groups of vesicles, occurring chiefly about the face and genitalia. The eruption, preceded by slight malaise, appears in the form of pin-head and pea-sized vesicles, arranged in clusters, and accompanied by heat and swelling. The vesicles contain clear or cloudy serum, and show no disposition to rupture.

Herpes facialis, familiarly known as *fever blister*, occurs more often about the lips (herpes labialis), and generally accompanies some slight digestive disorder, colds, and fevers. The lesions become dry, form crusts, and disappear, being hardly worthy of treatment.

Herpes progenitalis, another form, occurring about the genitalia, is worthy of attention on account of the possibility of its being confounded with venereal disease. The lesions consist of groups of vesicles, more or less perfectly formed, upon a red base, running an acute course, and accompanied by uneasiness and slight burning, with, sometimes, pain. The chief characteristic of these lesions, as contra-distinguished from those of eczema, is their persistency to retain their form without rupturing. In *herpes præputialis*, in which the lesions are on the inner surface of the prepuce, they may, by rubbing on the glans, become macerated, and give rise to superficial excoriated patches which may easily be mistaken for chancroid. But the fact that the lesions occur in groups, which is not the case in any other vesicular disease other than herpetic diseases, should always prevent such an error of diagnosis. The treatment is simple, consisting of lotions of sulphate of zinc, five grains to the ounce of water, lead-water, diluted aqua ammonia, boric acid; also dusting powders. All forms tend to recover, although recurrences are common. *Herpes gestationis* is a rare herpetic disease resembling eczema, occurring in the latter part of pregnancy. It is sometimes a grave affection. It usually disappears after delivery. It is accompanied by intense itching.

Herpes zoster is an acute inflammatory disease, characterized by groups of vesicles upon inflamed bases, with neuralgic pains. It runs its course in two or three weeks, and between the fifth and tenth day the eruption is at its height, consisting of characteristic groups of yellowish, glistening vesicles, retaining their form, and showing no disposition to rupture. In the old it is more serious than in the young, there being more pain, and the affection in general runs a more serious course. The varieties of the disease are made according to the regions affected. Thus, we have herpes zoster capitis, facialis, nuchæ, brachialis, pectoralis, femoralis, cervico-brachialis, dorso-pectoralis, etc. Occurring about the eye, it may be attended with the loss of that organ. It is generally unilateral, and seldom attacks the same individual twice. The lesions may ulcerate so as to leave scars, which may be distinguished from those of syphilis in that the former are in groups, and, moreover, occur in the line of the nerves.

Among the causes, cold, mechanical violence, unusual exertion, exposure, injuries to nerves, may be enumerated. It is a disease of the nerves and ganglia, consisting of an inflammation, as shown by post-mortem examination. In severe cases, treatment is called for, and positive relief may be sometimes given with the faradic current. General treatment may consist of the administration of saline aperients, iron, and arsenic. Locally, lotions of sulphate of zinc, carbolic acid, Grindelia robusta, flexible collodion and morphia, and the sulphide of zinc lotion, are all of service.

Herpes iris, regarded by some as allied to, or as an advanced stage of, erythema multiforme, may be defined as an acute inflammation characterized by groups of vesicles and vesico-papules, arranged in concentric rings, with a display of variegated colors. The lesions spread peripherally, and their color is sometimes striking, the tints being present in no other disease. It runs an acute course in one or two weeks, attacking, as a rule, the hands and forearms. It occurs generally in spring or fall, and is not contagious. There is little difficulty in distinguishing it from herpes zoster, pemphigus, or erythema multiforme, by the peculiar color of the lesions. Treatment is seldom called for, the lesions disappearing in a few weeks. The parts should be protected from friction, and a sedative lotion used.

MILIARIA is an acute disease of the sweat-glands, the lesions consisting of pin-point and larger vesicles and papules, accompanied by a pricking or tingling sensation. The eruption is abundant, and may occur in successive crops, accompanied or not by sweating. It is met with most frequently in adults or in infancy, especially in the weakly and debilitated. It is common in the tropics, and is also seen in this country and in Europe. The disease must not be confounded with sudamina, in which there is no inflammation. It runs an acute course, followed by slight desquamation. Relapses are common. The treatment consists of saline aperients, diuretics, quinia, and iron, lotions of black wash, lead-water, sulphate of zinc, sulphate of copper, etc.

POMPHOLYX is a disease allied to pemphigus, is rare, and does not possess very striking characteristics. The lesions consist of vesicles and blebs, excoriations with maceration and exfoliation. It occurs mostly about the hands (cheiro-pompholyx), fingers and palms, also the toes and soles of the feet, and is a disease which has

been much discussed in the last ten years. It is a distressing disease, and incapacitates the individual for a period of weeks, there being considerable oozing and exfoliation of epidermis, accompanied by burning.

PEMPHIGUS, either acute or chronic, exists in two varieties, pemphigus vulgaris and pemphigus foliaceus, characterized by the appearance of blebs. It is a rare disease, out of 16,863 cases of diseases of the skin collected by the American Dermatological Association, there being only 14 cases. The lesions come out in successive crops, rupture, and disappear, without leaving any trace. The patient, after a variable time, may sink into a marasmus and die of exhaustion. In pemphigus foliaceus, the blebs do not come to perfection, but break down, giving rise to much moisture, causing maceration and exfoliation of the epidermis.

The causes are attributed to a disturbed nervous system, in some cases in which severe mental strain or depression has existed. The treatment consists in the long-continued use of arsenic in moderate or full doses. Locally, mildly stimulating lotions and ointments, as in the case of vesicular eczema, are useful.

LICHEN RUBER is characterized by pin-head or pea-sized, flat, angular, or pointed, shining and scaly, dull-red papules, which are discrete or confluent, running a chronic course. There are two varieties, plane and acuminate, and these may be slight or severe. In this country, the disease is mild, compared with central Europe. It occurs either localized or diffused, and attacks the hands, forearms, especially the flexor surfaces, the thighs, and trunk in the tracts of the nerves. It is always succeeded by pigmentation. The cause is assigned to nervous influences. It occurs more often in women than in men, and lasts a variable period, usually months. The peculiar appearance of the lesion is sufficient to distinguish the disease. The treatment consists in the administration internally of arsenic, quinine, etc., with regulation of diet, and hygiene. Locally, to allay the itching which is at times an annoying symptom, lotions of tar, carbolic acid, or thymol may be used.

PRURIGO is a disease seldom seen in this country, but it is common in Europe, and especially so in Vienna. It is a chronic inflammatory disease, characterized by small, rounded, numerous discrete, solid, pale-red papules, with thickening and itching. It is liable to be confounded with papular eczema, yet the pale, yellowish color of the lesions, and the fact that they generally attack the extensor surfaces, and occur usually in children, are in most cases sufficient to distinguish it.

LICHEN SCROFULOSUS is a chronic inflammatory disease, characterized by small, reddish or yellowish, grouped, scaly papules, without itching, occurring in scrofulous subjects. It is very rarely encountered in this country. It is observed chiefly in Austria.

ACNE is an important disease on account of its frequency throughout the civilized world. It is sometimes so slight as to be unworthy of notice, while at other times it is extremely disfiguring, running a chronic course and being not infrequently difficult to cure. It may be defined as an inflammatory disease of the sebaceous glands characterized by the formation of papules, tubercles, or pustules, or a combination of these lesions, usually chronic, and occurring, as a rule, about the face.

The face is the common seat of the disease, although it is occasionally found upon the back between and over the shoulders, about the neck, and upon the chest. It is most frequently met with in early life, between the ages of fifteen and twenty-five years. There are two chief varieties—*acne papulosa* and *acne pustulosa*—sometimes occurring together, sometimes alone. A subvariety of the papular form, in which the lesions are small and discrete, is known as *acne punctata*, and a subvariety of the papular or pustular form, in which the lesions are accompanied by marked induration, is called *acne indurata*. Another inflammatory acne is produced by tar and the iodide and bromide of potassium, and is termed *acne artificialis*.

The causes are very numerous. It is met with in both sexes, and occurs most frequently in light-haired subjects. It usually begins at the age of fifteen or sixteen, and runs its course in one or two years, or becomes chronic, and continues five, ten, or more years. Among the causes, general debility, cachexia, anæmia, dyspepsia, constipation, and uterine disorders may be mentioned, the last not so much as is generally supposed. The pathology of the affection consists of an inflammation of a variable grade in and about the sebaceous gland, caused by disordered secretion, tending to the formation of pustules.

The diagnosis offers no difficulty in the majority of cases. The eruptions caused by the administration of the bromide and iodide of potassium may be known by their highly inflammatory character. There are two diseases with which it may be confounded—papular or pustular syphiloderma and variola. The lesions of a papular syphiloderm may or may not be around a sebaceous gland, while in the former the sebaceous gland is always involved. Then, again, in syphilis the papules develop slowly, and may be found in other parts of the body besides the face, while the acne papule develops rapidly, and is localized, as a rule, about the face. To distinguish it from variola, the absence of febrile symptoms is sufficient.

While certain lines of treatment are extremely valuable, there are some cases which prove most rebellious. The general health must engage the attention, and any functional disorder must be corrected. Dyspepsia or constipation not infrequently is present, and saline aperients are indicated, or a mixture known as "mistura ferri acidi," composed as follows:

℞.—Magnesii sulphatis, ... ℥ij.
Ferri sulphatis, ... gr. viij.
Acidi sulphurici diluti, . . . fℨj.
Aquæ menthæ piperitæ, . . fℨiv.

Sig.—One tablespoonful with a gobletful of water before breakfast.

Another similar mixture is the following:

℞.—Magnesii sulphatis, . . . ℥iss.
Potassii bitartratis, . . . ℥ss.
Sulphuris præcipitatis, . . . ʒss.
Glycerinæ, ... fℨss.
Aquæ . . . . . fℨiijss.

Sig.—One tablespoonful with water before breakfast.

Cod-liver oil, iron, arsenic, mineral acids, quinine, and glycerine, are the most useful general remedies. In some cases, especially of the pustular variety, calcium sulphide in doses of one-tenth to one-half grain gives good results; in other cases it is of doubtful value. In

certain cases in which there is a tendency to a hyperæmic state, ergot, in the form of ergotin, three to five grain doses, or the fluid extract, half drachm doses, sometimes acts happily. Arsenic may be used with advantage in cases of the punctate papular variety of the non-inflammatory type. Diet is an important factor in the treatment, and it must be properly regulated. Food and drink have a positive influence in many cases of acne.

Local treatment is always necessary, and in many cases alone suffices to effect a cure. It is usually best to begin with applications of hot water, once or twice a day, the water being dabbed on the part until it becomes red. This may also be used together with soft soap, or, where the skin is sensitive, castile soap. The best soft soap is that which is imported, it should be transparent and free from bits of caustic and other impurities. Another preparation of soap which may be used is "spiritus saponatus kalinus," composed of two parts of soap and one of alcohol, perfumed with some essential oil. To stimulate the circulation of the skin in slugglish acne, friction may be used with sand soap or sulphur soap. All comedones should be expressed, and all pustules laid open with a sharp-pointed bistoury. Where the skin is oily, one of the following lotions may be used.

℞.—Sulphuris præcipitatis, . . . ʒi–ʒiij.
Glycerinæ, ... ʒss.
Adipis benz., ... ʒj.
Ol. rosæ, ... gtt. j.—M.
Sig.—Apply twice a day.

℞.—Sulphuris præcipitatis, . . . ʒj.
Etheris, ... fʒiv.
Alcoholis, ... fʒiijss.—M.
Sig.—Apply morning and evening; shake before using.

℞.—Sulphuris præcipitatis, . . . ʒiv.
Camphoræ, ... gr. x.
Tragacanthæ, ... ℈j.
Aquæ calcis,
Aquæ rosæ, ... āā fʒij.—M.
Sig.—Apply twice a day; shake before using.

Vleminckx's solution, diluted one part to five or ten, is often of value. It is prepared as follows:

℞.—Calcis, ... ℥ss.
Sulphuris sublimati, ... ʒj.
Aquæ, ... fʒx.
Coque ad fʒxj et filtra.

In applying these remedies the patient must take from fifteen minutes to half an hour each time. A valuable agent for the removal of comedones is a paste composed of equal parts of sulphur, glycerine, alcohol, ether, and carbonate of potassium. This is to be rubbed in well, and subsequently washed off with water. Where the sulphur preparations are of no avail, mercurials may be tried. Corrosive sublimate, in an emulsion of almonds, or in a lotion with alcohol and ether, one or two grains to the ounce; also ointment of ammoniated mercury, fifteen to forty grains to the ounce of lard, may be employed. Care must be exercised not to use mercurials in connection with sulphur preparations, or while giving internal medicines containing sulphur, which are eliminated through the skin, *e. g.*, calcium sulphide, as the skin becomes discolored by the formation of sulphide of mercury.

Acne rosacea may be defined as a chronic hyperæmic or inflammatory disease of the face, characterized by redness, dilatation of bloodvessels, hypertrophy, and acne. There are three stages of the disease: 1. Hyperæmia; 2. Hyperæmia with dilatation; 3. Hypertrophy. The course of the disease is chronic, and the onset is gradual. The face is the seat of the affection, and the part usually attacked is the nose, either the tip or about the alæ. Both sexes are liable, but in men it is usually more severe; in females it seldom goes beyond the second stage. In the third stage there is a new growth of tissue and bloodvessels, and the nose becomes increased in size, giving rise to the so-called rhinophyma, or "pound-nose" of German authors. The subjective symptoms are variable, though seldom marked.

The causes are numerous and diverse. Anæmia and chlorosis and menstrual disorder in women, nervous affections, excessive indulgence in alcoholic liquors, repeated and prolonged exposure to cold, etc., all act as exciting causes.

The first stage is due to a venous congestion which causes stasis, and gives rise to the hyperæmia. After a time, the congestion continuing, the walls of the bloodvessels yield to the abnormal strain, and dilatation is effected, and the second stage is established. The passive congestion gives rise to the formation of new connective tissue, in which again new bloodvessels are formed, which cause the part to increase in size, even becoming lobulated, producing the third stage of the disease.

It may be confounded with the tubercular syphiloderm, yet its chronicity is sufficient to distinguish it, together with absence of ulceration. From lupus vulgaris it may be differentiated by the absence of the characteristic yellowish or reddish lupus tubercles and the cicatrices. It may also be mistaken for lupus erythematosus, especially when the latter disease occurs on the nose; but there the fine scales, with minute prolongations extending into the ducts of the sebaceous glands, are usually sufficient to establish the diagnosis.

In the treatment, the same class of remedies may be employed as in simple acne. In the first two stages, ergot is sometimes of value. Linear scarification will in many cases reduce the redness; also electrolysis, by obliterating the bloodvessels. Carbolic acid, one part to three or four of alcohol, is often of service. Where there is much hypertrophy, ablation by the knife or cautery is the only efficient mode of treatment.

COD-LIVER OIL, COMBINED WITH THE MURIATES OF AMMONIUM AND SODIUM.[1]

By JOHN P. CURLEY, M.D.,
VISITING PHYSICIAN TO THE NEWPORT HOSPITAL, NEWPORT, R. I.

In these days of many medicaments, and their innumerable applications to diseased conditions of the human organism, new remedies being constantly added to the list, and, for a time, at least, partially displacing the older ones, physicians are prone to

[1] Read before the Newport Medical Society.

be too easily led to disregard or depreciate the value of many remedies, good in themselves, but which, from defective preparation, the addition of inert and worse than useless compounds, or too brief a trial, may be found to be of little or no service to the patients for whom they are dispensed. Perhaps no substance used in medicine has been subjected to greater abuses, and, in consequence, has been brought into greater disrepute, than cod-liver oil. For this there are several reasons. Much of the so-called cod-liver oil is not cod-liver oil at all; more of it has been too carelessly and recklessly "tried out," and the livers of other fishes are frequently used to compensate for a deficient supply of the cod livers; added to which may be mentioned imperfect methods of refining, rendering it impossible to eliminate from the oil its organic impurities. To these fraudulent and pernicious practices it is largely due that cod-liver oil has not maintained, so well as it should, the high place in the category of therapeutic agents for which it was manifestly destined. On the other hand, with the exception of iron, mercury, and potassium, there is no remedy that will exert a more beneficent influence over so wide a range of diseases. In all lung affections that threaten disintegration and decay, cod-liver oil is confessedly the most valuable remedy at our command, when used in the incipient stages of the disease; and yet, as all know, it is too often powerless when the malady has passed beyond a certain point. Its value in scrofulous diseases, rickets, convalescence from wasting fevers, dentition, and whenever a general alterative and tonic effect is desired, is everywhere conceded; but I propose merely a brief study of the best method of its introduction into the economy, with a view to obtaining the best results.

It is reasonable to assume that almost all maladies for the cure of which cod-liver oil is indicated, are attended, if not pretty frequently sustained, by malassimilation, and those functional disturbances of the stomach and small intestine, so obstinate and difficult to allay, and which so often present a decided barrier to its administration. There can be no doubt, therefore, that the pancreas, whose secretion plays so important a part in the digestion of fatty substances, must, in common with the other organs of digestion and absorption, be weakened, and its function to some extent impaired; so that it would seem in very many (if not all) instances unwise to give cod-liver oil pure and in its crude form, when, from the very nature of things, it cannot be properly emulsified in the duodenum, even when not entirely rejected by the stomach. Happily, we have a means of overcoming this obstacle to its administration, and are enabled so to act upon the oil by trituration with solutions of gum, and in various other ways, as to break up its globules into microscopical granules, suspended in water by the gum; in other words, to form outside the body a "chyle" which may be readily assimilated within. Of all methods used for emulsifying cod-liver oil, I am convinced that the process of trituration with gum acacia is the best, and more nearly approaches the results reached by the pancreatic juice during digestion; for cod-liver oil should be absorbed as such, in its entirety, if possible, the better to economize and secure its virtues. There seems to be no doubt that it possesses certain specific qualities peculiar to itself, which are not known to exist in any other fish oil, and its adulteration by other oils, and their frequent wholesale substitution for it, while claiming its name, are evils for which the physician should be on the alert, nor too hastily conclude that cod-liver oil is inefficient in certain cases, when, perhaps, he may not be using that remedy, but unwittingly may expect its best effects from some oil of inferior quality.

It has become the custom of nearly all of the manufacturers of cod-liver oil emulsions which have become popular, and have obtained (and to some degree have merited) the confidence of the profession, to incorporate with their productions more or less of the phosphatic salts or the hypophosphites, believing them to be of material benefit when thus administered to the patients, and an auxiliary force of the greatest value to the cod-liver oil itself. It has not, however, been very clearly demonstrated that these salts act otherwise than as feeble tonics, and, certainly, it cannot be said of them that they fulfil the end for which they are prescribed, to wit, the reproduction in the system of the phosphoric element, the partial loss of which is supposed to be inevitable in strumous and tubercular diseases, and whatever condition may constitute or accompany the "phosphatic diathesis."

But while the phosphates and hypophosphites do not seem to merit the prominence accorded them as adjuncts to the cod-liver oil treatment, I believe that the muriatic salts, properly combined with the oil, lend to its action far more of specific value than any others yet used in conjunction with it. Niemeyer says: "The internal use of the alkaline muriate mineral waters, which is so often beneficial in simple catarrh, is equally useful in some cases of consumption" (*A Text-book of Pract. Med.*, vol. i. p. 243). The chlorides of ammonium and sodium have long been recognized as agents of some power in tubercular and other lung and scrofulous affections, acting equally upon the organs of nutrition and respiration, and I have found that after using a preparation of cod-liver oil, combining these salts, the happiest results have followed.

My attention was first directed to this, in some sense, new departure in the administration of cod-liver oil compounds by Mr. A. K Quinn, of this city, who prepares his own oil from fresh livers, and, having thoroughly purified it, emulsifies it with gum acacia each ounce of the preparation representing sixty-six per cent. of pure cod-liver oil and sixteen grs. of the muriates of ammonium and sodium. This should be taken in the ordinary doses in sweetened water or milk, dissolving readily in either, and it has been in almost all instances well borne by the stomach, with no disagreeable eructations.

I have prescribed it very frequently during the past year in a great variety of adynamic conditions, chiefly of the tubercular and strumous orders, and am justified in asserting that many times it has been

of marked and rapid service in arresting organic changes, and repairing weakened tissues, where other compounds had failed to manifest any curative power whatever.

As may be noted, there is no attempt at secrecy or privacy regarding the constituents of this remedy or its method of preparation, but, for convenience in prescribing, the originator has styled his production "Morrholeine," from *morrhua*, the cod, and attaches particular stress and import to the necessity of having a pure and thoroughly refined cod-liver oil used in its compounding, he having found by repeated experiments that without such an oil, a stable and palatable product cannot be secured.

I will briefly relate the medical histories of a few cases in which I have tested the virtues of the muriatic salts with cod-liver oil, selecting these from a number of which I have notes, as affording the most striking evidence of the good results obtained by their use.

Case I.—D. S., æt. 29; native of Rhode Island; late horse-car conductor of New York. Had been for nearly a year suffering from lung trouble, as shown by pain in chest, cough, free expectoration, emaciation, etc. Grew worse, and was taken to Charity Hospital, and after spending some time there, his friends were sent for to take him home to die. When brought here, he was unable to walk from the boat to a carriage, a short distance.

I saw him on the next day, and found him with signs of what I would call chronic interstitial pneumonia; there were dulness at both apices, prolonged expiration, and bronchitic râles. After allaying a distressing irritability of the stomach with the usual remedies, I prescribed morrholeine, which he continued faithfully. He came here in the early part of May, and was driving a hack on July 4th.

Case II.—M. M, mason's tender, aged 30; left Boston in April weighing two hundred pounds; came here to work, and thought that while coming down on the train and boat he aggravated a severe cold, which had troubled him, from time to time, for some months.

He worked here one week, growing worse all the time, and was then seized while at work with a pretty severe hemorrhage, which frightened him. He remained at his boarding-house two weeks longer, suffering from night-sweats, loss of appetite, a constant, sharp, and racking cough, and lost thirty pounds in weight. When I saw him, three weeks after his arrival, he presented a very bad appearance. His respirations were short and quick, his pulse rapid, and there were râles over both apices. I prescribed for him morrholeine and zinc and belladonna for his night-sweats, and in less than one month from the date of the prescription he was at work.

In neither of these above-mentioned cases was there any hereditary tendency to phthisis.

Case III.—J. R., clergyman, æt. 32; had had for several months a short, dry cough, night-sweats, a gradual tendency to dyspnœa on exertion, and was being treated for nervous prostration with the *comp. syr. of the hypophosphites*. In the latter part of August, his symptoms culminated in a severe hemorrhage, the quantity of blood expelled being nearly two quarts. On examination, the right apex was found indurated, with a harsh respiratory murmur for some inches downwards. I kept him in bed for three weeks, during which time he gradually improved in every way, his chief treatment consisting of the chlorides with cod-liver oil.

He has continued it faithfully since, and is now practically well. In this case there was a distinct heredity, proved by the fact of his father having died of phthisis.

Now, if the *hypophosphites* possess the power over lung-disease with which so many accredit them, surely here was an opportunity for them to exercise it, as my patient had taken them regularly and persistently for months, and they did not in any degree benefit him apparently, and certainly did not prevent him from passing almost beyond the possibility of recovery.

I could cite several other cases, but do not wish to occupy too much time, my desire being merely to direct attention to the good results which have attended the use of the chlorides of ammonium and sodium with cod-liver oil in my hands, and I hope that many others will be equally fortunate, and establish beyond doubt the therapeutic value of the combination.

CASES OF KNEE-JOINT EXCISION, WITH REMARKS.[1]

By CHARLES McBURNEY, M.D.,
VISITING SURGEON TO THE ST. LUKE'S AND BELLEVUE HOSPITALS, NEW YORK.

Mr. President: In my paper to-night I am able merely to present the histories of all my cases of knee-joint excision as a contribution to the statistics of that operation, with especial reference to the danger and mortality arising from this operation.

Case I.—Frank Halle, aged twelve. Parents gave a history of synovitis complicated by abscess, occurring at the age of two. Both knees were affected. When the patient came under my observation at the Orthopædic Hospital, the right leg was flexed so as to form an angle of twenty-five degrees with the thigh. No extension was possible. The left leg was flexed as much, but could be extended so as to form an angle of ninety degrees with the thigh. The boy moved by sliding about on his toes, the heels touching the buttocks. Both knee-joints were surrounded with cicatrices of old sinuses.

On June 10, 1878, I attempted to excise the right knee joint, as the head of the tibia was displaced very far backwards, and forced extension aided by tenotomy had been attempted on the left leg without success. Owing to the great displacement of the leg backwards, and the shortening of the hamstring muscles and posterior ligaments, I was obliged to remove no less than four inches of bone, so that the femur was sawn after several sections had been made, far above the epiphyseal line. The operation was done under the constant use of the carbolic acid spray, and a complete Lister dressing

[1] Read before the New York Surgical Society, March 25, 1884.

was applied. A plaster-of-Paris bandage was applied to the thigh and to the leg, the plaster appliances being connected by hoops of iron curved over the joint outside of the dressing. Horse-hair drainage was used. This case required a great deal of nursing. Numerous sinuses formed, one abscess had to be opened in the popliteal space, and necrosis of a portion of the lower end of the femur occurred. Bony union was not firm until May 6, 1883, nearly ten months after operation. By June 2d, patient was able to walk with a support on the left side, such as a chair or crutch. It was my intention to operate upon the other knee, but permission to do so was refused by the parents.

CASE II.—Kate Lyons, aged twenty-nine. This patient came under my observation in December, 1882, at Bellevue Hospital. Ten months before this time, she had had an attack of acute articular rheumatism, which especially affected the right knee-joint. I found the leg flexed at a right angle with the thigh, rotated outwards, displaced outwards and backwards, and firmly ankylosed. The patient was quite helpless from the deformity, was weak and anæmic, and her urine contained granular casts. I excised the joint on January 4, 1883. The patella was firmly adherent to the femur, and was removed. To allow proper extension of the leg it was necessary to make a second section of the femur. The bones were drilled at two points and silver wires inserted, which were brought out between the flaps. Full Lister precautions were used throughout the operation, and a Lister dressing applied. Rubber drainage-tubes were used. A plaster splint was applied to the thigh and another to the leg, and these were connected by iron brackets passing over the knee. Seventeen days after the operation I found it necessary to continue the leg splint down to the toes in order to prevent eversion. The limb confined by the plaster apparatus was kept upon an inclined plane, this position aiding in steadying the femur, and also allowing the under portions of the dressing to be easily inspected. The average temperature during the seventeen days following the operation was 100.2°. On one occasion, seven days after the operation, symptoms of carbolic acid poisoning appeared, and the temperature suddenly rose to 105.2°. A bichloride dressing was applied, and the temperature at once fell to 101.2°. On no occasion was there the slightest reason for anxiety about the case, except when the symptoms of carbolic acid poisoning were present. A collection of pus formed in the upper synovial pouch, and the silver wires also caused suppuration along their track. The patient was discharged able to walk well on April 28th, a little less than four months after the operation. The shortening in this case is 1.75 inches.

CASE III.—Charles McKenzie, aged fifteen, a healthy, well-developed boy, suffering from atrophy and deformity of the left lower extremity and left half of the pelvis, due to infantile paralysis, came under my care, at St. Luke's Hospital, on February 1, 1883. The thigh was partially flexed upon the body, the leg flexed at a right angle to the thigh, rotated outwards, and displaced backwards. No ankylosis existed, but the greatest extension possible was 112°. The muscles of the thigh, leg, and foot were completely helpless, and the whole limb looked like that of a boy ten years of age. The shortening, as ascertained by careful measurements, was estimated to be five inches. This patient was able to move about with difficulty on crutches.

I excised the knee-joint on February 17, 1883. The tibia and femur were wired together with silver wire. Two rubber drainage-tubes were used, one on the inner, and the other on the outer, side of wound, and the wound was washed with carbolic acid and water, 1 to 40, and covered with gauze wet with the same solution. Dry gauze and borated cotton were bound over this dressing. A plaster splint, such as is here shown, was then applied, a single curved iron bracket passing over the knee, and a single nearly straight one passing behind. The limb was then kept upon an inclined plane.

This patient's temperature rose on the next day to 104°, on the second day sank to 103°, and by the sixth day stood at 99.6°. From this time on, there was never any temperature above 100.6°, and that temperature was reached only once.

In this case, also, pus formed in the upper synovial pouch and along the track of the wires.

Firm bony union was found on April 28th, two months and eleven days after operation.

By May 4th, all sinuses were soundly healed, and with an artificial shoe constructed to make up for the extreme shortening, the patient was walking about with two sticks by July 4th.

At the present date, he is able to walk easily and for long distances with a single cane. I cannot present this patient, as he lives in the northern part of this State. I have a very recent report of his condition from his physician.

CASE IV.—Serreno Cappa, aged twelve. Five months before coming under my care, at St. Luke's Hospital, this boy had received a kick upon the right knee, the injury being rapidly followed by arthritis, abscesses, and caries of the head of the tibia. On examination I found numerous cicatrices about the knee, the soft parts much thickened, great pain on motion, and two open sinuses leading to carious bone in the head of the tibia. The leg was slightly flexed, and motion of four or five degrees could be made when the patient was etherized. I determined to excise the joint, as the only means of saving the leg, and to remove the carious bone at one operation. This I was able to do May 29, 1883. The section of the femur was made just below the epiphyseal junction, and the usual section of the head of the tibia. This last section opened several small abscesses in the head of the tibia, two of which had fistulous tracts leading out through the skin. These I scraped out from the sawn surface, thus making grooves on the upper end of the tibia, in which drainage-tubes of rubber could lie without separating the femur and tibia. Three tubes were inserted and brought out in the line of union of the skin. Drainage-tubes were also inserted at each lower angle of the incision, to drain the superficial wound. The patella was removed and silver wires were used to assist apposition, and a plaster-of-Paris

splint was applied similar to the one here shown, with a single bowed bracket in front, and a nearly straight one behind. A peat dressing was applied. The first dressing was changed on the fifth day, and after that frequent dressings were made; and, thorough irrigations with a 1 to 40 solution of carbolic acid, with the exception of the evenings of the third and fourth days, when it reached 100.6°, the temperature did not rise above 100° up to July 10th, six weeks after operation. The uncovered soft parts then became swollen. I took out the wires and removed the plaster splint, substituting for it a posterior wooden one. Three days later there was a sudden rise of temperature to 104°, and erysipelatous redness appeared on the leg. This attack rapidly subsided, for two days later the temperature was 99°, and did not again rise.

By September 15th, three months and a half after operation, all sinuses had closed, firm bony union had taken place, and patient was able to use the leg freely. The shortening in this case is one inch and a half.

Case V.—Agnes Watkins, aged six. Patient came under my notice at St. Luke's Hospital, May 23, 1883, being transferred from the Orthopædic Department. Had been treated conservatively at the Orthopædic Dispensary and at St. Luke's for some three years without success. Numerous abscesses had formed and opened, and there were extensive ostitis and caries of the lower end of the femur on the right side. The leg was flexed and displaced backwards.

May 25th I excised the right knee-joint, the section of the femur being made well below the epiphyseal line, and the whole articular surface of the tibia being removed. The patella was not adherent and was excised. Two wire sutures were used, the twisted ends being brought out in the line of the wound. A drainage-tube of rubber was inserted at each lower angle of the wound. A plaster apparatus including the foot, similar to that shown, was used, excepting that as the limb was so light and small, no anterior bracket was required. Peat dressing was applied. The dressing was changed every few days, and a 1 to 40 solution of carbolic acid used as a wash through drainage-tubes. Six weeks and a half after the operation the wires were removed, and perfect union of the bones found. Two months after operation the patient was up and walking about.

The temperature in this case reached 100.2° on the evening of the sixth day. On no other occasion did the temperature go above 100° until the wires were removed; it then went up to 102°, but at the end of two days was again normal. Present shortening less than three-fourths of an inch.

Case VI.—Matthew Carey, aged seven, came under my care at Bellevue Hospital, in July, 1883, giving a history of synovitis of the right knee-joint originating in a traumatism received eighteen months ago. I found the knee flexed on the thigh at an angle of forty-five degrees, rotated outwards, and the head of the tibia markedly displaced backwards. I divided the hamstring tendons and attempted to straighten the limb, but, as so often happens in such cases, the shortened posterior ligaments could not be made to yield, and the head of the tibia was still more displaced. The attempt at straightening was also followed by a partial paralysis of the muscles of the front of the leg.

October 18, 1883, I excised the joint, finding almost complete destruction of cartilage without ankylosis. This operation was done with constant irrigation by a bichloride of mercury solution, 1 to 1000. Silver wire used and ends brought out. A deep continuous suture of catgut was used in sewing up the capsule, and a similar one for the superficial wound. A rubber drainage-tube was inserted at each angle of the wound, and, to provide against the accumulation of fluid in the upper synovial pouch, a short tube was passed through the skin into the upper end of this sac. The wound was dressed with iodoform, carbolized gauze, and cotton, and was put up on a posterior wire splint.

The first dressing was removed thirteen days after operation, and tubes removed. The wound had entirely healed except at points of entrance of tubes. During November and December a dermatitis without constitutional disturbance, set in. This was probably due to the irritating effects of the carbolized gauze.

The highest temperature reached in this case was 101°, on the evening of the day after the operation, and again once on the third day. The average temperature was very nearly 99.5°. The position is good, and the boy can walk; but to-day, five months after operation, bony union is not quite perfect.

Case VII.—George Betz, aged seven, a very strumous boy, whose right knee had been previously opened by one of my colleagues at Bellevue Hospital for the relief of an obstinate synovitis, with caries of the patella, and fungous disease of the joint. The patella had been removed, and the joint carefully scraped out. The operation had apparently been entirely successful for a time, but, under my observation, pus formed in the joint, found its exit through the anterior part of the upper synovial pouch, and the probe readily detected caries of the lower end of the femur.

January 31, I excised the joint, finding extensive disease of the lower end of the femur. The operation was done under the constant irrigation with 1 to 1000 bichloride solution. Catgut was employed for ligatures and sutures; the wound was dressed with iodoform, carbolized gauze, and cotton; bone drains were used; and a *complete* plaster splint applied *over all*. This dressing was not removed till six weeks after the operation. Pus was found in considerable quantity beneath the dressing. A line of prominent granulations existed throughout most of the wound. Bony union was almost complete.

The highest temperature reached in this case was 100.4°, on the twentieth day after the operation; the average temperature throughout was below 100°. I think it was a mistake to attempt to leave this first dressing on so long. Slight overextension, which might have been rectified at at earlier date, now exists.

Case VIII.—Mary Finkbeiner, aged twenty-six.

When eight years old, this patient received an injury to her right knee, which was followed by a synovitis of ten weeks' duration. She has been able to walk, with a limping gait, up to six months ago, when renewed disease of the joint forced her to use crutches. When the patient came under my care, at St. Luke's Hospital, in February of this year, I found a large abscess in the head of the tibia, opening externally about two inches below the joint, and above, through a large opening in the articular cartilage, communicating freely with the joint. Bony crepitus on motion was marked, the joint much swollen, and the leg partially flexed. General condition of patient very bad.

March 7, I excised the joint, the section of the tibia opening a large abscess already referred to, and the first introduction of the drill on the inner side opening another. Both of these abscesses were thoroughly scraped, and openings for drainage-tubes made into them through the anterior surface of the tibia, *about two inches below the joint.* Rubber drainage-tubes were introduced through these openings. The operation was done with constant irrigation of bichloride solution, a deep and superficial continuous suture being used in the wound. A short bone drain was inserted at either angle of the wound. It was impossible to use wire or other means to hold the bones together, as the abscesses referred to had so weakened the head of the tibia. The wound was dressed with iodoform and gauze, and the limb bandaged to a posterior wooden splint, with foot-piece, to prevent rotation of the leg. This dressing was untouched until yesterday, twenty-two days after the operation, when I found the wound soundly healed, without pus. I removed the wooden splint, and put up the limb in the bracket splint shown. This case, like the preceding two, is not finished, and is only presented as bearing upon the question of immediate danger from the operation. The temperature record of this case is unusually good for a patient twenty-six years old. On the evening of the day after operation, the temperature reached 100.4°. With that exception, the temperature has never risen above 99.4°. It is noticeable, too, that, although no wires were used in this case, it was very evident at yesterday's examination that the bones were in close apposition.

The method of operating was nearly the same in all cases, a slightly curved incision being made from the back part of one condyle across the front of the joint below the patella, to the back part of the other condyle. The patella was removed in all the cases, even when not diseased, and also as much synovial membrane and diseased capsular tissue as possible. In only the first case was any attempt made to use a drain passing from one side of the joint to the other. Two silver wires were used to suture the bones in every case except the last. The apparatus used has varied, but in five cases I have used the plaster splint with brackets similar to the one shown. This apparatus can be readily made and applied by the operator immediately after the operation, and allows of moving and dressing the limb very readily. I think that the best method is the one I adopted in the last case, that of putting the limb immediately after operation in a permanent dressing, and fastening it to a posterior wooden splint with foot-piece; this provides against the chance of having to remove the plaster apparatus soon after the operation in case of swelling of the parts, or on account of accidental soiling of the plaster. At the end of two or three weeks the plaster splint with bracket can then be applied, and any desirable change in the position of the leg made.

I have never tried the incision recommended by Hahn, of Berlin, which passes across the joint *above* the patella. It would doubtless allow of a more ready removal of the upper synovial pouch. Such a removal is, I think, of considerable importance, as in most cases which I have seen there has been a tendency to the accumulation of fluid at that point.

With regard to suturing the bones with wire, or nailing them together, as Hahn did in so many of his cases, I am inclined to think that neither procedure has very great value. In an ordinary resection of the knee the posterior ligament is uninjured, and forms a thorough posterior support, and the natural shortening of the hamstring muscles must draw the tibia upwards. Rotation seems to be the movement most to be feared, and that can be avoided by the retaining apparatus.

PERIPHERAL PARAPLEGIA.

BY JOHN FERGUSON, M.A., M.D., L.R.C.P.,
ASSISTANT DEMONSTRATOR OF ANATOMY, TORONTO SCHOOL OF MEDICINE, TORONTO, CANADA.

IT is with some hesitation I adopt the caption "Peripheral Paraplegia" to designate a class of cases in which a correct diagnosis is by no means an easy matter. We meet with a patient who gives us a history of good health up to the present attack, who states that his illness began somewhat suddenly, that it could not be traced to any injury, and yet he is more or less completely paralyzed in both legs, or in both hands and arms, or in all these members.

On going more fully into the details of the case, we gather that the patient has been working at some exposed employment, in which he has had repeated wettings and chills; or that he has been called to stand upon cold, damp ground, with a current of air passing around his feet and legs; or that he has been engaged in draining during the cold season of the year. From such occupations, so far as I can ascertain, comes the disorder on which I purpose making a few remarks, recording same cases, and asking the profession to express an opinion.

The trouble usually begins with a feeling of general fatigue; the patient complains of a want of energy for his accustomed work; the limbs feel strange, and yet it is hard for the patient to say what they really feel like. There is some loss of control over them; this loss of power may be but slight, or it may suddenly become quite alarming. There is a tingling in the affected parts; but the sense of touch may remain only slightly or not at all impaired for a time. The tingling becomes more and more annoying, the weakness of the limbs gradu-

ally increases, until the patient is not able, or scarcely able, to walk. From this stage, things may begin to mend, and, after a protracted illness compared with the severity of the symptoms, there is a restoration to complete health.

In other cases, however, the symptoms grow worse than those depicted above, and the patient takes to the bed. The legs, as just stated, have suffered first, but the disease does not stop there. By and by, functional derangements set in. There is more or less difficulty in passing urine, the bowels are constipated, the patient loses weight considerably, and the flesh is soft. In severe cases, in which the illness is marked in its symptoms, and protracted in duration, the girdle-pains of paraplegia are at times quite pronounced.

Looking at the nervous condition of the patient more closely, it will be seen that the paralysis, or, rather—for a time—paresis, was slight. On close inquiry, it is found that the state of the sensory nerves first drew the attention of the patient. The strange feeling of the limbs was first noted. This feeling is subjective rather than objective. The patient realizes that the sensation is disturbed, even although the tactile power remains fairly good. In succession to this state of sensory derangement come the motor aberrations. Steadily the paretic condition creeps on, until the power of the limbs is wholly, or almost wholly, gone. So far there is no evidence of anything being wrong with the spinal cord; but this does not always remain so, and after a time there are signs which lead us to believe that it is also affected. Of the symptoms here, I have mentioned a few, such as the girdle-pains, constipation, and difficulty in voiding urine.

Where is the lesion situated which causes this form of paralytic trouble? Three places suggest themselves: the brain, the spinal cord, or the peripheral nerves. With regard to the brain, we must note that a paralysis occurring from any lesion in this organ is generally unilateral. To this statement the only exceptions of any moment are: 1. General paralysis of the insane; and, 2. When the injury, or disease, involves that part of the brain where the fibres cross. Now, the disease in question is bilateral, and, therefore, cannot depend upon any lesion affecting only one side of the cerebrum. The history of the case clearly excludes general paralysis of the insane, or disease in which the cerebral fibres decussate.

Turning to the spinal cord as a possible place for the cause of the disturbance, several points come up for examination: 1. The disease is bilateral—just as it might be if due to injury or disease of the cord. 2. There is either loss or impairment of the functions of both motor and sensory nerves; as we would find from a spinal cause. 3. There is the girdle-pain. 4. The organic functions of life suffer—similarly to cases in which the origin of the disease is undoubtedly spinal in its nature.

With regard to the peripheral nerves, we see: 1. That the diseased action begins at a distal part of the body, as the foot and leg. From this, as a starting-point, it gradually advances until parts more centrally situated are implicated. 2. That the girdle-pain appears late in the progress of the case; and if the patient be fortunate enough to make a speedy recovery from the earlier stages of the paralysis, this symptom may be slight, or not at all marked. 3. That the loss of power over the bladder and bowels is also a late feature of the case, and appears to come on quietly and insidiously, as the case is advancing from a lighter to a severer type. 4. That the abnormal condition begins to show itself first in the sensory nerves, which never escape. The opposite of this is the case with regard to paraplegia from the spinal cord. The motor are more likely to suffer first than the sensory, and, indeed, the latter may not become affected at all.

From this description, I have no hesitation in regarding these cases as of peripheral, and not central, origin. The lesion commences in the distal ends of the nerves, and thence advances along the nerves towards the centre of the body, involving larger and larger trunks as it advances. Finally the cord is reached, and once this has taken place, there is no further difficulty in understanding the girdle-pain, or the loss of action in the bladder and bowels.

Case I.—William G., æt. 55; healthy. There was no history of syphilis in this case. Previous to the attack he had been a watchman, and was exposed a great deal to cold and wet. The attack began in the late fall weather. He complained of tingling in his feet. Soon after this, his hands were similarly affected. He began gradually to lose power over his legs. In about three weeks from the commencement of his attack he could not walk. Although a strong man, he had almost entirely lost grasp in his hands. He steadily grew worse. In the seventh week of his illness, the bowels and bladder became irregular and sluggish. The catheter had to be used. At the end of the eighth week he suffered a good deal from the girdle-constriction around the body. Things remained in this condition for upwards of five months, when a slow improvement took place. By the end of the summer following he had largely regained his health, although he has never been up to his former degree of vigor, and there is a very slight amount of paresis still remaining.

Case II.—James L., æt. 48; yardman. This patient was greatly exposed—frequently very warm, and then chilled. Had a severe chill a week before I saw him. When he came first under my notice, he was complaining of constant tingling in his feet and hands. Sense of touch still good. He had some difficulty in walking, as his knees would go out from under him. By the end of the second week the sense of touch was greatly impaired, though it was never lost entirely. When sitting on a chair, he could make no effort to raise the thigh with my hand placed upon his knee to exert a downward pressure. The patellar tendon-reflex was completely absent on both sides. In ten days more he could not walk at all. On the thirty-first day from my first visit, he was seized with severe girdle-pain, which caused much suffering for the next month, when all the symptoms began to abate, and he made a good recovery. No trouble with the bladder, but the bowels became torpid.

Cases III., IV., and V. present so many features similar to the above that I forego giving any detailed history. In Case IV., that of a Presbyterian clergyman, I might mention that he had been exercising himself with clubs, and felt warm. He directly drove a distance of about ten miles. The day was cold. To this he dates back his illness. He suffered greatly from shooting pains in the back and legs.

These five cases have fallen under my own observation. Three other similar ones I saw in the clinic of Prof. Grainger Stewart, of Edinburgh, and it was with no small degree of interest that I heard that learned scholar comment on their probable nature. Whatever might be their cause, one thing seemed clear to his mind—that they were of peripheral origin. Since then, the cases I now record have fallen under my notice, and the more I think over the matter, the more firmly do I become convinced of the truth of the above opinion.

Now, what is the pathology of such cases? I have not had the opportunity of making a post-mortem in any such case, as those I have seen recovered. On this account, it is impossible for me to express a positive opinion. Still, judging from the causes, such as cold and exposure, that we find preceding the disease, and looking carefully at the clinical history presented by persons so attacked, there is a good deal to support the view that there is a general neuritis of the peripheral nerves. This is not all conjecture, however. A careful research of the literature bearing in any way upon this question, reveals the fact that patients having the symptoms of this form of paralysis, and dying of some other cause, did, on examination, yield evidence of inflammation of the nerves.

The prognosis, so far as can be ascertained, is good.

The treatment which I have adopted consisted in good sustaining measures. Of the two classes of drugs, the arterial contractors and the arterial dilators, I have obtained the best results from the latter; and of these, none has acted as well as aconite. Shampooing of the limbs and surface of the body is also useful, and should be followed by an efficient friction with a good, thick bath-towel, until the skin begins to feel tender. Stimulating agents, as mustard, may be put in the water, or light sinapisms to the surface, changing their place of application.

THE RADICAL CURE OF ARTIFICIAL ANUS.

By WILLIAM A. BYRD, M.D.,
OF QUINCY, ILLINOIS.

In The Medical News for February 2, 1884, there is an editorial article with the above heading, in which is discussed the relative value of the old and classic operation introduced by Dupuytren, and variously modified since his day so as to meet the requirements of different surgeons, and the excision of the affected portion of the bowel and the stitching together of the upper and lower ends, as first practised by our accomplished countryman, Dr. R. A. Kinloch, of Charleston, S. C. The writer concludes, from results of reported cases of enterectomy, with suturing of the divided ends of the bowel, that it will not bear the crucial test of time and experience, and that the far less dangerous operation of Dupuytren will be the operation of the future surgeon. But these are the words: "Hence we think that the procedure should be reserved, first, for the more simple cases in which compression, cauterization, and the enterotome and autoplasty have failed; secondly, for cases of great destruction of the intestinal wall with extensive prolapse of the mucous membrane, and with or without invagination of the upper portion of the gut; and, thirdly, for the cases in which the ends of the intestine are so disposed that, even after the destruction of the éperon, there could be no reëstablishment of the natural course of the feces, as would happen if the lower end of the gut were placed above the upper end, if the two segments crossed each other at a right angle, or if there were a notable difference in the calibre of the two ends of the intestine."

I wish to call the attention of the reader to a plan that I believe will be found as safe as that of Dupuytren, and as effective in joining the ends of the bowel by suture, when that method proves a success. The method that I propose is to free the bowel from all attachments at the site of the artificial anus; then remove a section from each end of the bowel, opposite the attachment of the omentum, obliquely from the omental border, so that the opening into the bowel will be elliptical in shape, and the long diameter of the opening twice as great as the transverse diameter. Then the edges of the bowel should be brought together carefully with the peritoneal coats in apposition, the ends coming together in a V-shape, leaving a small portion ununited at or near the omenal border. The portion of bowel with the opening in it should then be attached to the opening in the abdominal walls, so that all gases that form would have a free escape. This procedure would free the operation from the danger of over-distention, which—if the operation is done quickly, and with proper precautions as regards cleanliness—is the chief factor in the production of a fatal issue. This diminutive opening would likely heal up without further interference.

I have operated for the closure of artificial anus three times, but have never adopted the method here suggested, as no case has presented since the matter suggested itself to my mind. I feel sure the method can be successfully carried out by most of our surgeons, and I hope that some one will shortly demonstrate its feasibility.

I have in six cases excised a portion of the bowel and sutured the divided ends into the opening in the abdominal wall, making an artificial anus, for intestinal obstruction, and none of the patients have died under the second month after the operation, and none from the effects of the operation, and three are living and are in perfect health now; one operated upon October 9, 1878, another January 21, 1882, the other one in September, 1882. The difference in the calibre of the upper and lower ends of the bowel need not be an objection to the performance of the operation, as that portion having

the larger calibre can be closed with sutures so as to allow of the smaller portion fitting it, or the smaller piece can be cut off diagonally enough to fit the larger opening. Of course if the bowel crosses at the point near where the artificial anus is, so as to have the lower piece present from above and the upper from below, enough of the canal will have to be excised to correct the trouble. In one case I sutured the ends of the bowel together parallel to each other, so as to insure not catching tissue that I did not want in my enterotome when the operation for the radical cure was performed. If the operation should fail on account of non-closure of the opening, then the plastic operation may be performed, with an almost assured success, that I first described in the *Medical and Surgical Reporter* for October 25, 1879, and also in the Address in Surgery, delivered by me when Chairman of the Surgical Section, before the American Medical Association, at its session in St. Paul, in 1882.

I wish to emphasize the benefits to be derived from leaving an opening for the escape of the gases that almost always form and complicate recovery from nearly all operations upon the abdominal viscera. I called attention to it in a paper entitled, "Abdominal Section in the Treatment of Ulceration and Perforation of the Cæcum and the Appendix Vermiformis," read before the Surgical Section of the American Medical Association, in Richmond, in 1881, when I used these words: "Another thing that I wish to call your attention particularly to is the benefits derived from having an artificial anus formed. This is not a fictitious advantage, as it allows the gases that form in the bowels to escape without distending them, and, perhaps, causing small cracks in the peritoneal coat, inducing peritonitis or paralysis from over-distention."

416 Jersey Street, February 18, 1884.

MEDICAL PROGRESS.

Removal of Malignant Tumor of the Bladder.—Prof. F. Guyon reports the case of a man, æt. 58 years, who had abundant and persistent hæmaturia; on examination a diagnosis of vesical tumor was made. In spite of absolute rest and various methods of treatment, the patient continued to lose blood, and Guyon decided to explore the bladder. Having opened the viscus, by the hypogastric operation, he found a tumor springing from the right wall and supported by a pedicle an inch and a half or two inches long. It was easily removed by the serre-nœud, and the point of attachment was scraped with the nails and the curette. There was very little hemorrhage. Two drainage-tubes were put in, and a Lister dressing applied. The patient began to improve immediately, the urine remaining bloodless from the time of the operation, and in about twenty days the wound was completely cicatrized. The cases reported by Billroth, Volkmann, Kocher, Humphrey, Thompson, Bazy, and Guyon (who has performed the operation in other cases), show that the operation is both justifiable and demanded under these circumstances.

Guyon is in favor of the hypogastric operation, in exploring for tumors, because: 1. It has been clearly shown that the suprapubic operation is relatively easy, and much less dangerous than the perineal. 2. It gives much more room than the perineal section, because it enables the operator freely to explore the viscus and see what he is doing.—*Ann. des Mal. Génito-Urin.*, March, 1884.

The Treatment of Suppurating Buboes by Compresses.—O. Petersen, in an article on this subject, says that so soon as fluctuation is detected the buboes should be widely incised and emptied, and syringed with carbolic or corrosive sublimate, solution; after the bleeding has ceased iodoform should be dusted on. The wound is then filled with salicylic wadding, a pad of this or of tow placed over it, this covered by oiled paper, and the whole fastened by a spica bandage. Unless the discharge is profuse, this dressing may remain untouched for eight or ten days. The average time of healing by this method in one hundred and fourteen cases was only twenty-three and three-tenths days, while the time required in twelve cases without this dressing, was fifty-three and eight-tenths days.—*Centralbl. f. d. klin. Med.*, February 23, 1884.

A New Transfusion Apparatus.—At a recent meeting of the Académie de Médicine, M. Dieulafoy exhibited a new transfusion apparatus made by Collin. The injection of the smallest quantity of air into a vein is avoided, as whatever air may find its way into the apparatus immediately accumulates in a receptacle at the top. There are no valves in the instrument, small balls of hard rubber being used instead. Two cuts, illustrating the mechanism of the instrument, may be found in the *Revue de Thérap.*, January 30, 1884.

Iodoform in Cancer of the Cervix Uteri.—Dr. Castré particularly recommends (*Thèse de Paris*, July, 1883) the following formula, first advised by M. Gillette:

℞.—Iodoform,	ʒivss.
Sulphate of quinine,	℈ij.
Powdered charcoal,	ʒiv.
Essence of peppermint,	gtt. lx.—M.

Thus prepared, iodoform may be added to other mixtures which it may be desirable to use. In cancer of the cervix, Castre recommends this preparation in powder, applied, on a cotton tampon, directly to the ulcerated surface. The ulcer should not be scraped or interfered with in any way before applying the tampon. This application may be made every two, four, or even ten days.—*Bull. Gén. de Thérap.*, February 29, 1884.

Transfusion in Bright's Disease and Diabetes.—M. Dieulafoy recently reported to the Société des Hôpitaux, the case of a man æt. 54 years, who had had abundant and repeated epistaxis, into whom about ƒʒiv of blood were transfused, with the happiest results. The new blood acting by its quality and not by its quantity, modified the blood of the patient and acted as a hæmostatic. This success has given to Dieulafoy the idea of introducing transfusion as a therapeutic measure in certain dyscrasic diseases, particularly Bright's disease, as has already been done twice by Bartels, in uræmia.

In the two cases published by Dieulafoy, there may be noticed a considerable amelioration of the general symptoms, and an enormous diminution of the quantity of albumen. The second case was that of a woman, who passed three grammes of albumen and twenty-four grammes of urea in a day, before the transfusion, and only eighteen centigrammes of albumen and thirteen grammes of urea afterwards. M. Dieulafoy questioned if a complete cure could not be obtained by repeated transfusions if the treatment was commenced early. M. Dujardin-Beaumetz did not believe transfusion capable of effecting good results when there is organic lesion. He did not see how transfusion could repair an altered kidney.—*Ann. des Mal. Genito-Urin.*, March, 1884.

Treatment of Peripheral Neuralgia by Osmic Acid.—Dr. A. Eulenburg, of Berlin, says, in a communication on this subject, that the observations published by Delbastaille on the treatment of certain tumors (sarcoma and scrofulous lymphoma especially) have been confirmed by others. Lately, Neuber has used from ten to twenty-four injections of osmic acid in two cases of sciatica, and in one case of trigeminal neuralgia, with complete success.

When the tendency to recurrence of the neuralgic attacks is considered, the results of this treatment do not seem to be very encouraging. Twelve cases are tabulated, including sciatic, lumbo-sacral, brachial, intercostal, occipital, and trigeminal neuralgia; of these, three, all recent cases, were cured, two being sciatic, and one brachial; in five cases there was no change for the better, and the remaining four were improved, other treatment being substituted in three of these. The number of injections in these cases varied from three to fourteen, extending over from one to six weeks, the injections being made over the seat of greatest pain, in order, if possible, to obtain a direct action by diffusion of the acid to the perineurium. The injections were made of a one per cent. aqueous solution in doses of ♏v. Eulenberg cautions that the solution should be kept in the dark, as otherwise it becomes black; and for this reason it is better to use a freshly prepared solution.—*Berliner klin. Wochens.*, February 18, 1884.

The Administration of Paraldehyde.—As a pure hypnotic, says Prof. Dujardin-Beaumetz, paraldehyde is superior to morphine and chloral. The sleep is more calm, the awakening is easier, and is not accompanied by the headache and other bad symptoms which invariably accompany the use of opium. But paraldehyde is powerless in pain. In insomnia, especially that of morphiomaniacs, it is an excellent drug.

M. Yvon gives various formulæ for its administration; as paraldehyde f℥jss, alcohol (90°) f℥vj, simple syrup f℥jv, tincture of vanilla ♏lxxv. Dose, f℥v to f℥j in sweetened water. It may be given in what Yvon calls the hydro-alcoholic solution—paraldehyde f℥ss, alcohol (90°) f℥j, boiling water f℥j. This is a 1 to 50 solution, the dose of which is f℥ijss to f℥v or more. This may be given in a little sweetened water, or in an aromatic infusion, as tea, mint, etc. The aqueous solution is, paraldehyde f℥j, boiling water f℥jss, the dose of which is about f℥ss. Instead of pure water, any distilled aromatic water may be used; or ♏lx of paraldehyde may be dissolved in f℥ijss of water. Another formula is, paraldehyde ♏xv to f℥j, simple syrup f℥j, water f℥ij, tincture of vanilla gtt. xx. To be taken in one or two doses. The vanilla may be replaced by tincture of canella, or some form of mint or anise. It may be given in elixir, paraldehyde f℥ijss, alcohol (90°) ℥jss, tincture of vanilla f℥ss, water f℥j, simple syrup f℥ij. Dose, about f℥ss, in water.—*Bull. Gén. de Thérap.*, January 30, 1884.

Amputation of the Uterus by the Elastic Ligature for Chronic Inversion.—Prof. A. Mazzuchelli, of Pavia, reports the case of a woman, æt. 35 years, who had inversion of the uterus dating from her seventh labor. After several ineffectual attempts to restore the organ to its proper position, Mazzuchelli decided to remove it by means of the elastic ligature. The uterus was drawn down, the ligature thrown around it by means of the Desault polypus serre-nœud, and was then replaced in the vagina. Thirty hours afterward the organ came away. Antiseptic injections and powders were thrown in, and the patient was soon cured. This is the seventh Italian case, all of which recovered.

The statistics collected by Denucé show that of thirteen cases in which the elastic ligature was used, only one died, while the lowest mortality for any other operation for inversion is from the progressive ligature, 15.87 per cent., and from this to 33.33 per cent. in other operations.—*Annali Univ. di Med. e Chirurg.*, Jan. 1884.

Therapeutic Uses of Lobelia.—In a recent communication to the Société de Thérapeutique Dr. Fournier states that he has successfully used the tincture of lobelia inflata, in doses of ♏xv–xxx, in several cases of cardiac dyspnœa, and in two cases of pulmonary congestion, and with good results in the third stage of phthisis. As lobelia alone is nauseating, it should be combined with polygala. Huchard uses the following formula, which is well borne by the patient:

℞.—Iodide of potassium, . . . ℥ij.
Alcoholic tinct. of lobelia,
Alcoholic tinct. of polygala, . . aa f℥ij.
Extract of opium, . . . gr. iss.
Distilled water, ... ad f℥viij.

Dose—Tablespoonful morning and evening in chronic bronchitis and asthma.

M. C. Paul has used lobelia and iodide of potassium with success in catarrhal asthma, ♏xx of tincture of lobelia to gr. viij of iodide of potassium.—*Revue de Thérap.*, March 1, 1884.

Treatment of Chronic Vaginitis.—Dr. Martineau states that he has found in his service at the Lourcine Hospital that salicylic acid mixed with powdered gum arabic and wheat flour, according to the following formula, gives good results:

℞.—Salicylic acid, ... 3 parts.
Wheat flour, ... 5 "
Powdered gum arabic, . . 1 "

This powder is applied to the whole of the internal surface of the vagina by means of an insufflator.—*Ann. des Mal. Genito-Urin.*, March, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 12, 1884.

RECENT TESTS FOR ALBUMEN.

In a recent discussion on albuminuria by the Glasgow Pathological and Clinical Society (*Glasgow Medical Journal*, March, 1884), Dr. WILLIAM ROBERTS, of Manchester, said of the tests recently suggested that they possess extreme sensitiveness, but that they all have the serious drawback of frequently giving a reaction with normal urine. With urines that contain a large or moderate amount of albumen, the reaction is quite unmistakable; but with such as contain but a small quantity, or only traces of albumen, their reactions require to be controlled by heat and nitric acid before they can be accepted as conclusive. He further found that the old tests—heat and nitric acid—but especially the heat test, when performed with certain precautions, present a delicacy, a certainty of action, and freedom from fallacy which render them distinctly superior to any of the new tests.

Serum albumen and globulin, the two known morbid albumens in the urine, are what we seek to recognize. This being the case, says Dr. Roberts, any test which requires strong acidulation with an organic acid is open to the objection that it precipitates mucin, the essential constituent of mucus, which appears to be present in larger or smaller quantity in all urines. This fact, he says, throws out the tungstate, mercuric iodide, and the ferrocyanide of potassium.

The best test for mucin, according to Dr. Roberts, is concentrated solution of citric acid, which should be used as nitric acid by Heller's method. When a solution of citric acid is thus overlaid with urine, an opalescent zone makes its appearance between the two. Acetic and lactic acids are less suitable, because too light to sink to the bottom of the tube; but acetic acid, if mixed with one-third its bulk of glycerine, acquires a density sufficient for the purpose.

The *heat test* for albumen is performed by Dr. Roberts as follows: Ten cubic centimetres, or three fluidrachms, of urine are placed in a long test-tube, so that it will form a column of two or three inches. To this is added a single drop of acetic acid. The upper half of the column is then heated to brisk boiling. If albumen is present, even in minimal quantity, the upper, boiled portion of the column will show opalescence, in contrast with the lower half, which remains unchanged. If the urine be alkaline, it should be carefully neutralized by adding successive drops of acetic acid until litmus paper shows a faint acidity, and then the final single drop of acid is added before boiling.

Even if the urine possess its natural acidity, and be turbid from lithates—which, of course, should be filtered off or allowed to subside—it is better to add a drop of acid if it is desired to bring out the maximum sensitiveness of the boiling test. By using this small and definite quantity of acid the mucin reaction is avoided, as well as the risk of preventing the precipitation by the use of too much acid. In this manner, Dr. Roberts says, albumen may be detected in a watery solution which contains only one part in 250,000! Surely we need no more delicate test than this.

He does not tell us, however, how to avoid the errors which may arise where comparatively large amounts of albumen are present, but where, in consequence of its previous combination with an acid or alkali, there is formed an acid-albumen or an alkali-albumen, neither of which is precipitable by heat. This error can only be thoroughly guarded against by using nitric acid, according to Heller's method, or, better, Dr. Roberts's own acid-salt solution.

With regard to the nitric acid test, Dr. Roberts says that it is necessary to wait thirty or forty minutes before the utmost delicacy of the test is exhausted, and that the faint hazy zone, which is only fully developed at the end of thirty minutes after the addition of the acid, is just as certain a sign of the presence of albumen as a zone that develops immediately, or after the lapse of one minute.

We confess this method of securing delicacy by the acid test is new to us. We had supposed that to wait beyond a minute or two for the development of the white zone was fatal to the value of the test; for it is at this time that the cloudy belt of acid urates makes its appearance, while anyone who has had much experience with Heller's test knows that when

a small quantity of albumen is present it is soon dissolved by the excess of nitric acid, even where a decided zone appears at the junction of the two fluids.

In fact, while we agree entirely with Dr. Roberts as to the delicacy of the heat test, we consider the nitric acid test far from delicate, although it or the acid-salt solution is still necessary to check the heat test where considerable albumen is present but is not precipitable by heat.

Dr. Roberts also calls attention to a globulin reaction, to which attention has not heretofore been directed. It is based on the fact that this substance, which almost always accompanies serum albumen in urine, is held in solution by sodium chloride and other neutral salts always present. But when such urines are largely diluted with ordinarily pure water, the percentage of neutral salts is so reduced that the globulin falls out of solution and forms a cloudy precipitate. The test is thus applied: Fill a urine-glass or test-tube with water, and let fall into it a succession of drops of albuminous urine. In many cases, each drop, as it sinks, is followed by a milky train, and when a sufficient number of drops have been added, the water assumes throughout an opalescent appearance, as if a few drops of milk had been added to it. The addition of a little acetic acid causes the opalescence to disappear. This reaction, says Dr. Roberts, appears to be due to globulin, or, rather, paraglobulin.

It is certainly an interesting chemical experiment thus to determine the presence of globulin in an albuminous urine, but as it neither adds to nor detracts from the pathological significance of an albuminous urine, the busy practitioner is scarcely likely to make much use of this test at present.

In a very interesting communication to *L'Union Médicale*, No. 34, March 6, 1884, M. CHARLES TANRET, the discoverer of the iodide of mercury and potassium test, replies to the objections which have been made against it in common with several of the recently suggested tests for albumen, on the ground that peptones and certain vegetable alkaloids, especially quinine, are similarly precipitated by it.

In the first place, he gives the correct formula, which he says has been erroneously quoted by Dr. Tyson in his note read before the Philadelphia County Medical Society some weeks ago. It should be as follows: bichloride of mercury, 1.35 grammes; iodide of potassium, 3.32 grammes; acetic acid, 20 cubic centimetres; distilled water enough to make 100 cubic centimetres. The resulting reagent is the double iodide of mercury and potassium, the chloride of potassium being without effect.

This fluid does not require the previous acidulation of the urine to be tested. It is to be noted that the precipitate is resoluble in an excess of albumen, but this source of error is obviated by adding an excess of the reagent. The reagent should be added as long as the cloudiness increases, and when the precipitation of the albumen is complete, its resolution is possible.

As to the precipitation of peptones and alkaloids, M. Tanret says this source of error may be avoided by simply warming the tube, or adding a little alcohol, by both of which measures these substances are redissolved, while a cloud due to albumen is permanent. On recooling the warmed tube the cloudiness, originally produced by peptones and alkaloids, returns.

As to the delicacy of the test, Tanret's original experiments proved that it would show one part of albumen in 2000 of water, but if the test fluid is overlaid by urine, its delicacy is increased tenfold, a beautiful white disk being formed at the intersection of the two liquids.

The advantage of this test over the picric acid, which is at once equally delicate and liable to the same objections, is found in its perfect colorlessness, and the consequent more striking contrast it affords to the urine with which it may be overlaid.

RUPTURE OF THE URINARY BLADDER.

RECOVERY after rupture of the bladder is so infrequent that the case recorded by DR. R. F. WEIR, in the *Medical Record* of March 29, 1884, which illustrates the value of affording a free outlet for the urine already extravasated and that which is subsequently secreted, cannot fail to interest our surgical readers.

A laborer, twenty-eight years of age, who had urinated shortly before, was struck on the pelvis and left hip by a mass of falling earth. A slight ecchymosis of the scrotum and a spot of blood at the meatus led to the passage of a soft catheter, which gave exit to a moderate amount of bloody urine, which became clearer as it flowed. There was no evidence of pelvic fracture, and during the first twenty-four hours the instrument was used three times, and tenderness was experienced in the hypogastrium. On the following day, there was marked suprapubic dulness with tenderness, which extended four inches above the pubes and into each groin, the wall of the belly above the dulness was somewhat rigid; the ecchymosis of the scrotum and perineum was very pronounced; a soft and painful spot was detected by rectal palpation on the left side of the prostate; the urine was passed at times voluntarily, and was not diminished in amount; and the temperature was 99°. Two days subsequently, the pulse and temperature having in the meanwhile risen, and increasing tympanites, tenderness, restlessness, and disposition to vomit having appeared, a pint of bloody, but undecomposed, urine was evac-

uated from behind the symphysis by a median abdominal incision, and a rent, commencing along the left side of the roof of the prostate, was detected in the antero-lateral wall of the bladder, by means of a median perineal incision. A drainage-tube was then passed through the suprapubic incision and the laceration, and confined by a suture at the former situation as well as at the perineal wound, and a second tube was retained in the bladder through the incision in the perineum. The cavity of the extravasation and of the bladder having been washed out with a 1 to 2000 sublimate solution, the wounds were dressed with iodoform gauze. The progress of the case was most satisfactory. The tube in the bladder was removed on the third day; the patient himself withdrew the other tube on the fifteenth day, when the urine was voided by the penis, and he was discharged at the end of another fortnight.

In making the diagnosis of laceration of the bladder, Dr. Weir states that if, after the catheter has evacuated its contents, it "passes in further, giving exit, in an ebb and flow movement corresponding to the respiration, to an additional quantity of urine, and this possibly of a different depth of color from that first drawn, the pathognomonic symptom is reached," and that the rupture is intraperitoneal if the beak of the instrument passes through the upper and back part of the viscus. In the absence of this sign, dulness on percussing the hypogastrium and the iliac fossæ is an important symptom, and points strongly to extraperitoneal laceration. The dulness, which is due generally to extravasated urine, increases more or less rapidly, and does not change its position with the movements of the patient.

Dr. Weir thinks that for ruptures involving the peritoneum, laparotomy, with closure of the vesical wound by means of sutures, is indicated, but that extraperitoneal rents should not be closed. In regard to this point, our own opinion is that sutures should be employed in all cases in which the laceration is accessible, and that the advice of Stein, that the lips of the rent in the bladder should be sewed in the abdominal wound, is injudicious, since, in the event of recovery, it will give rise to partial retention of urine.

THE REPORT OF THE GERMAN CHOLERA COMMISSION.

We published in our last issue the full text of Dr. Koch's sixth report upon Asiatic cholera, in which are contained some facts worthy of special note.

The first of these is the emphatic declaration that the bacilli found in the intestines of cholera patients are parasites belonging peculiarly to cholera, and that they are the cause of cholera. It is true, inoculation-experiments have failed with cholera bacilli; but, according to Koch, the demonstrative force of the facts above given is not weakened, as the same phenomenon meets us in other infective diseases, including leprosy and enteric fever.

The second is that the bacilli of cholera possess peculiar characters by which they can be distinguished with certainty from other bacteria. Thus, they are always somewhat curved, suggesting the shape of a comma, and sometimes they are almost semicircular. In pure cultures, these curved bacilli often give rise to S-like forms, and to wavy lines of varying length, the former of which correspond to two individuals, the latter to a number which have remained attached after proliferation. They possess, also, very active movements. In gelatine they form colorless colonies, which at first look as if they were composed of glittering fragments of glass. Gradually, these colonies cause the gelatine to melt, and then spread themselves out to a moderate extent; and by this peculiar appearance they are distinguished with great certainty from other colonies of bacteria.

Another important fact, consistent with what is known of the etiology of cholera, is that when the linen of cholera patients, after having been soiled by their dejections, has been kept for twenty-four hours in a moist state, the cholera bacilli are found to have multiplied in the most extraordinary manner. Hence the fact that the linen of cholera patients has so often proved the cause of infection. On the other hand, the bacilli die off, after drying, more quickly than almost any other form of bacteria—as a rule even after three hours' drying, every vestige of life has disappeared. This explains the fact that infection so seldom follows upon direct contact with cholera patients.

The same comma-like fungi were not found in any of a large number of similar, but not identical, conditions, such as dysentery and enteric catarrh. They were found to be confined to the bowel, having been only twice recognized in the vomit. They first appeared with the commencement of the disease, being few in number, but increasing as the attack culminated and diminishing as it declined.

Since it seems certain that the cholera bacillus enters the system through the stomach, and since it cannot live in the normal stomach, the question naturally arises what conditions permit its transmissibility through the stomach into the intestine, and there cause the disease. These as yet are undetermined; but it has been observed that those are especially liable to cholera who are suffering with indigestion. Such a cause as this is reasonable, and the supposition accords with our experience in other diseases. It is also conceivable that some form of persistent condition, other than that of the spore, exists, in which the bacilli can remain alive for weeks in a dried state, and in which they are capable of resist-

ing the destructive action of the gastric juice, but from which they can be developed when mingled with intestinal fluids.

VAGINAL HYSTERECTOMY.

PROFESSOR MUELLER, of Bern, has recorded four successful cases of removal of the carcinomatous uterus by the vagina, in the *Wiener Medizinische Wochenschrift*, No. 8, 1884, by a method which differs in several essential particulars from the operations heretofore practised.

With a view to avoid hemorrhage, he, in the first place, compresses the abdominal aorta with the fist, which is, as a rule, easily done, the walls of the belly being relaxed and thin in this class of subjects; and, secondly, preserves intact the large vessels by limiting his incisions to the anterior and posterior walls of the vaginal vault, thereby not interfering with the sides, in which the vessels ramify, that under other methods require many ligatures. The uterus having been retroverted through the posterior opening, provisional threads are cast around the broad ligaments, and the undivided vaginal walls, when the uterus is split vertically into two symmetrical halves. The resulting pedicles, which consist of the broad ligaments and the vaginal walls, are now tied with double threads, and divided near the two halves of the uterus, which are then removed. The vessels of the stumps, three or four in number, are next tied, whether they are bleeding or not, when the compression of the aorta is relaxed, and any other vessels of the stumps or of the vaginal wound are secured. After careful cleansing of the wound with a solution of corrosive sublimate, the stumps are permitted to retract, the ligatures are cut off on a level with the vulva, and a carbolized tampon is placed in the vagina. The latter is removed at the expiration of twenty-four hours, and the parts douched several times a day with the sublimate solution. The ligatures come away in the third week.

The novelty of Mueller's operation consists in the means employed to prevent hemorrhage, in not circumscribing the cervix with a complete incision, and in the vertical division of the uterus. The preservation of the lateral limits of the vaginal vault renders retroversion of the uterus somewhat difficult, but this is more than compensated for by the avoidance of bleeding. Hemorrhage does not attend the splitting of the uterus, as it has been guarded against by provisional ligation of the pedicles.

The merits of this procedure will be the more readily appreciated if it be compared with the operations of Schroeder and Fritsch, which were described in THE MEDICAL NEWS for December 15, 1883. Fritsch, who does the first cutting at the sides, states that he has sometimes had as many as twenty ligatures on a single side, and, as bleeding is one of the great dangers of vaginal hysterectomy, the method which best prevents it is, other things being equal, the one to be preferred.

EXTRAARTICULAR WIRING OF THE FRACTURED PATELLA.

IN the issue of THE MEDICAL NEWS for December 8, 1883, we called attention to the risks of approximating the fragments of a broken patella with silver wire. The risks, it will be remembered, are due to opening the joint, which suppurated in nearly one-fourth of all the cases in which the procedure had been resorted to, and which led to a mortality of nearly six per cent. It was for these reasons that we ventured to express the opinion that antiseptic suture of the patella should be restricted to old cases, or those in which ordinary measures had failed to bring about union.

DR. VAN DER MEULEN, of Utrecht, has recorded in the *Lancet* for March 22, 1884, three cases of recent fracture successfully managed with the wire suture without opening the knee-joint. In all of the operations, which were performed on the eighth, ninth, and twenty-fifth day after the accident, he found, after removing the clots of blood from between the two fragments, that a thin, but distinct, membrane existed between the posterior edges of the fragments, which acted as an effective barrier between the fragments and the cavity of the joint. By taking care to depress this membrane with a probe—the membrane being partially organized clot, or rather young connective tissue—while the canals are being drilled and the suture inserted, the cavity of the joint is not opened, and the risks of the ordinary procedure are averted. In one case the operation had to be repeated on account of refracture, but the final result was very good. In the remaining cases the functions of the joint were intact.

While Dr. Van der Meulen is to be congratulated upon his demonstration of an occluding membrane and upon the operation based upon its presence, which he has devised, we fancy that the generality of surgeons will demand a favorable experience with the method founded upon several hundred cases, before they will resort to it in recent fracture in preference to more simple measures.

IN the issue of THE MEDICAL NEWS of last week it was incorrectly stated that Dr. Packard had lost his case of ligation of the primitive iliac artery. The successful cases were those of Kümmell, McKinley, Mowret, and Packard for hemorrhage. Bickersteth, Caldas, Cock, Garviso, Hey, Lange, Luzenberg, A. B. Mott, V. Mott, Peace, Richter, Salomon, Sands, Schoenborn, and Syme for aneurism, and Guthrie for a pulsating tumor simulating an aneurism.

We hope the members of the profession in Philadelphia will not be led incautiously to give their approval to a series of impertinent questions with regard to vivisection which are being distributed by the so-called Anti-vivisection Society. The signing of the postal card upon which the questions are printed, binds the signer to favor certain legislation with regard to vivisection which is altogether unnecessary and uncalled for.

REVIEWS.

A Manual of Obstetrics. By A. F. A. King, M.D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, Washington, D. C., and in the University of Vermont, etc. Second edition. 12mo. pp. 338. Philadelphia: Henry C. Lea's Son & Co., 1884.

In the preface to his first edition, the author speaks of his little book, as "an outline of the rudiments and essentials of obstetric science," and offers it as a groundwork for the obstetric student, by which he may be "prepared to understand and assimilate the extensive knowledge and classical descriptions contained in larger and more elaborate text-books." He confesses to have drawn very largely from the three well-known college text-books of Playfair, Leishman, and Lusk, and his manual may be regarded as an analysis of the usual teachings of obstetrical lecturers. The second edition corrects some of the opinions of the first, and is an improvement upon it, although only enlarged by a few pages. The fact that the first edition was so soon exhausted, shows that the work is popular, and that there is a demand for this style of treatise; one which can be carried about and referred to when a busy practitioner is desirous of refreshing his memory upon essential methods, etc., and has not time to consult a more elaborate treatise. As a condensation of knowledge, the book is quite a success, as the author has the faculty of saying a good deal in a few words, and he generally selects the best line of medication for treatment. Anyone wanting an analysis of obstetric science, will do well to procure this little volume. A country doctor might often be made the wiser by referring to it on the road, when he might not be able to carry a more complete treatise.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, March 25, 1884.

The Vice-President, Charles McBurney, M.D., in the Chair.

Dr. A. C. Post presented a patient upon whom he operated two weeks ago last Friday for

OCCLUSION OF THE RIGHT NASAL CAVITY FROM DEVIATION OF THE SEPTUM.

There was at the same time a periostosis of the nasal process of the superior maxillary bone. He separated the side of the nose from the cheek, and turned it over in order to get access to the obstruction, and then removed the protruding part of the septum and some of the superfluous superior maxillary bone. The nose was then turned back and secured, and the traces of the incision would not be sufficient to attract the attention of casual observers. The occluded nostril was quite free. It was probably a congenital deviation.

Dr. McBurney remarked that such deviation usually occurs to the other side.

Dr. H. B. Sands had performed the same operation, and found that it was very much facilitated by the separation of the ala nasi. He did not open the septum, but removed the projecting cartilaginous swelling, and some of the bony growth situated along the nostril, and the patient recovered without deformity.

Dr. Post said that he had in several cases divided the columna nasi, where the deviation did not extend so high up, which facilitated the operation very much, and by closing the columna no deformity remained.

DOUBLE RUPTURE OF THE TENDON OF THE QUADRICEPS FEMORIS.

Dr. Markoe presented, in behalf of Dr. Weir, a patient, seventy-two years of age, who had ruptured the quadriceps tendon of both patellæ. There was immediately above the upper margin of the patella the usual depression, abrupt upon both sides. The accident was caused by slipping upon a piece of ice, one knee giving way, and the other tendon rupturing almost immediately afterward. There was not only the depression immediately above the patella, but also the sharp edge on either side indicated where the aponeurosis had not been ruptured. There were, therefore, two strong fibrous bands left, which enabled him to make some extension of the leg at the time of the injury. A good deal of extravasation of blood occurred about the parts. The patient was treated by placing the limb in a straight position; a large amount of effusion took place into one knee-joint, but in the other not very much inflammatory reaction exhibited itself. The injury occurred three months ago, and the patient was able to walk slowly. Both tendons had united equally well.

FRACTURE OF THE HUMERUS AND SCAPULA, COMPLICATED WITH SEVERE INJURY OF THE ENTIRE BRACHIAL PLEXUS, FOLLOWED BY PARALYSIS.

Dr. Gerster presented a boy, eight years of age, who was run over by a wagon December 10, 1883. The exact mode of injury was unknown. It was alleged that immediately after the injury he could clinch his fist. He saw the patient for the first time ten days after the injury, and found an anæmic boy, with the pectoralis and serratus region widely suffused and discolored. The armpit was filled by a hard mass (coagulum) which caused a curious bulging of the right pectoral region. Fracture of the upper third of the shaft of the humerus was easily made out, but the lengthening of the arm with a wide displacement of the head of the humerus from the acromion accompanied by local crepitus, and also the fact that this deformity could be easily reduced but immediately reappeared, made the diagnosis of fracture of the neck of the scapula clear. There was absence of both brachial and radial pulse; there was paleness of the extremity, no œdema, but absolute

motor and sensory paralysis of all the branches of the brachial plexus. The fracture of the humerus was dressed with three pasteboard splints, but the fracture of the neck of the scapula presented no easy problem. Finally it was found that the fragments could be best retained in position by raising the splintered arm up by the bend of the elbow on a series of turns of a bandage wrapped over the shoulder of the same side, fastening all these turns by a series of turns passed around the thorax, and by a loop of bandage passed around the neck over to the other axilla. At the end of three weeks there was consolidation, with slight deformity of the humerus. The deformity was due to the necessity of lifting the shoulder by the elbow. The fracture of the neck of the scapula still showed crepitus, and therefore the bandage was continued. A pressure sore developed over the olecranon. The deltoid, triceps, and biceps showed no faradic irritability on January 15. Sensation of the skin showed a marked variability. One day it extended down to the upper part of the forearm, to disappear three or four days after up to the middle of the arm. The first nerve to show constant improvement was the musculo-cutaneous; the most tardy was the musculo-spiral. From the tenth day after the injury neuralgic pains, located directly in the palm of the hand, were felt by the patient. Pressure on the deep portion of the axilla caused intense pain up to the eighth week, when most of the large blood-clot had been absorbed. At the same time choreic, jerky contractions of both shoulders and the head commenced to be developed, which very soon yielded to the administration of Fowler's solution continued for about six weeks.

In spite of frequent readjustment of bandages and much care, it was very difficult exactly to retain the outer fragment of the scapula in a correct position; this, and the absence of a sufficient protection of callus usual at this place, resulted in a ligamentous union, with slight deformity, but good function.

In the fifth week, the hand became puffed up, reddish-blue, much colder than the other, the nails showing a deeper tinge.

By the middle of February, the deltoid, biceps, brachialis internus, and triceps commenced to respond to the will, but not to faradism, a circumstance first observed by Erb, and confirmed by Leegard and others. On February 26 they contracted on faradic irritation.

Supination and pronation were first observed on March 11, supination being less complete than pronation. On the same day, flexion of the fingers, excepting the thumb, was fully noticed.

To-day, flexion of fingers and thumb is well marked, extension very incomplete, but noticeable, and the prognosis seems to be decidedly hopeful.

The flexors respond very well to the galvanic, sluggishly to faradic, irritation. The radial pulse is still absent.

It seemed fair to conclude from the injuries observed, and the neurotic symptoms following them, that the plexus brachialis must have suffered a very severe contusion and laceration by the displaced fragments. The statement voluntarily made by the relatives that the hand could be clinched shortly after the injury, seemed to indicate that no rupture of the radial and median nerves could have taken place. No special treatment as regards the nerve lines was instituted, attention being chiefly directed to maintaining a good general condition.

Dr. Gerster also exhibited another patient who had had injury of the radialis caused by the fall of a heavy board on the lower portion of the posterior aspect of the arm. The patient was unable to extend the limb, and there was also the characteristic paralysis of the radialis, accompanied by the flabby condition of the forearm. It was of three weeks' standing. The contusion was of the arm, above the elbow.

DR. MARKOE related a case which was pertinent to the history of the injury and subsequent progress of Dr. Gerster's first case, occurring in a gentleman forty years of age, who was run over by a hack. Precisely how he was struck, or how he struck when he fell, it was impossible to ascertain. Dr. Markoe found fracture of the surgical neck of the humerus, which was oblique in such a manner that the upper end of the lower fragment projected into the axilla high up. He was very much disturbed to find that there was no radial pulse, and there was absolute loss of sensation and motion below the middle of the arm. The hand was blue and cold, and for twenty-four hours he apprehended the occurrence of gangrene; but this did not occur, although no brachial or radial pulse returned, and their absence had been permanent. From the time of the injury, paralysis of the muscles of the forearm was complete. Anæsthesia manifested itself particularly along the distribution of the ulnar nerve, which could be mapped out perfectly by the distribution of the paralysis, which was absolutely complete. After a time, the patient was able to make slight flexion and extension of the fingers; he has not been able to flex the thumb. The trophic changes have been precisely as usual in these cases, and the limb presented a glossy, puffy condition, and the palm of the hand, particularly, has exhibited a good deal of perspiration.

Appreciating that there was considerable displacement of the fragments towards the axilla, Dr. Markoe endeavored to try and reduce them as well as possible; but he did not dare to place any splint on the inside of the arm, lest he should increase the injury already done by the fragment, and, therefore, applied a very thin pad in the axilla, leaving the arm steadied against the side of the thorax, and supporting the elbow. The case had gone on through the history which had already been given by Dr. Gerster. In the fourth week, neuralgic pains began, which were very severe, and were referred especially to the palm of the hand, but extended along the ulnar side of the forearm down the fingers, and along the dorsal aspect of the radial side. At the present time, the bone is not firmly united.

From the lack of support upon the inside of the arm one unfortunate result had occurred, namely, the pectoralis and latissimus had drawn the fracture toward the chest, and pressure upon the parts in the axilla still existed to a considerable extent. Although the symptoms of paralysis had modified, Dr. Markoe was still at some loss to know what to do further in the treatment of the case. He had used faradism only, but proposed to use the galvanic current after further trial of the faradic. Dr. Weir Mitchell had obtained remarkable results in the treatment of neuralgic pains so common in such cases by the use of stimulating applications to the parts

to which the nerves are distributed, and had applied blisters successfully. Dr. Markoe had used strong liniments in his case for the relief of neuralgic pains, and with considerable benefit.

Dr. Post had seen cases of traumatic paralysis which had been promptly benefited by the application of moxas, either along the course of paralyzed nerves or near the seat of injury. He had also seen marked relief follow the use of the actual cautery.

SUBCORACOID DISLOCATION OF THE HUMERUS; PARALYSIS OF THE SERRATUS MAGNUS; ARTHROTOMY.

Dr. Gerster also presented a patient, Jennie M., twenty years of age, who was thrown violently against a tub, and sustained a subcoracoid dislocation of the humerus. The nature of the injury seems to have been overlooked by some physicians who saw the patient shortly after the accident, since they treated it with liniments and electricity. Seven weeks after the injury the patient came under Dr. Gerster's care at the Mount Sinai Hospital. The diagnosis of dislocation complicated with marked paralysis of the serratus of the corresponding side was readily made out. Reposition did not offer the least difficulty, but the weight of the extremity alone was sufficient to cause the reappearance of the dislocation. The reduced humerus was kept in a normal position for five weeks by means of an ample plaster-of-Paris dressing enveloping the arm, shoulder, and thorax. When it was removed it was found that the tendency to the reappearance of the dislocation was unchanged, wherefore operative relief was sought.

Arthrotomy by the anterior incision was performed on December 11, 1883. It was found that the inner aspect of the joint capsule, the side facing the axilla, was abnormally relaxed, and therefore a piece, one inch long and half an inch wide, was excised from it while the arm was forcibly rotated outwards. A counter-incision was made into the posterior part of the capsule for drainage, and capillary drainage by a fascicle of catgut strands was established. The anterior wound was closed by sutures. The autopsy had revealed that in a state of dislocation the distance between the glenoid cavity and the apex of the head of the humerus was fully one inch.

Six hours after the operation very alarming septic fever set in, with a temperature of 103° F., and great sickness and dejection. Although no local signs of disturbance were visible, Dr. Gerster deemed it prudent to remove the stitches, open up the wound, and seek the cause of the infection. Among the seven catgut ligatures applied, three were found to be much thickened, turbid, and infiltrated with and surrounded by an areola of pus. The remainder of the wound was found to be normal, the rest of the ligatures being slightly thickened but transparent. Suspecting the quality of the catgut used for the capillary drainage of the joint, the fascicle was likewise removed and replaced by a rubber drainage-tube. The wound was treated openly. The temperature fell to the normal, and the case progressed favorably. The tube was removed at the end of the second week, and the wound healed at the end of eight weeks. Healing was retarded by an attack of erysipelas commencing from the opening made for the drainage-tube at a time when healing was nearly complete.

The function of the joint is now fair, but promises to improve and become normal, since mobility of it is considerable, although very little orthopædic treatment had been employed.

FRACTURE OF THE PATELLA.

Dr. F. Lange presented a patient, a man sixty-two years of age, who illustrated the usefulness of a limb after fracture of the patella, in spite of a distance of three inches between the fragments. The patient had had fracture of the patella several times, and the last time the injury occurred three or four years ago, and there was also rupture of the crucial ligaments, as evidenced by hyperextension of the knee-joint and great lateral mobility. The plan of treatment which Dr. Lange adopted was similar to that recommended by Dr. Little, and the immediate result was very good; but after a time the gap between the fragments began to increase and afterward became quite extensive, and measured three inches; and yet the patient was able to walk quite well, could go up and down stairs, and could extend the limb very well.

CHOPART'S OPERATION.

Dr. McBurney presented a patient with the following history: Wm. Burke, aged 33, was admitted to Bellevue Hospital, on December 25, 1883, suffering from severe frost-bite of the extremities of both feet. The feet were treated with soothing applications, such as charcoal poultices, up to January 17, 1884; on that day I operated upon both feet: from the right removing the toes only at the metacarpo-phalangeal articulations; on the left doing Chopart's amputation at the medio-tarsal articulation. The foot and leg were first thoroughly cleansed with a solution of iodoform in ether, and irrigation with bichloride solution, 1 to 1000, was kept up throughout. Catgut ligatures were used, and a continuous catgut suture applied to the skin wound. A single bone drainage-tube was passed through at the base of the flap from one side to the other. The wound was covered with protective, dusted with iodoform, and enveloped in carbolized gauze and cotton, *great care being taken to force the astragulus and os calcis into extreme flexion.* To aid this effort, a pasteboard splint was applied to the back of the leg and to the under surface of the stump outside of the dressing, and firmly bandaged so as to maintain the position of forced flexion. The highest temperature reached by this patient after operation was 100° on two evenings.

The first change of dressing was made fourteen days after operation at my clinic. The drainage-tube had disappeared, and the wound was completely healed without a drop of pus. At one point was a minute pin-head point of granulation.

Some months ago I reported to the Society a case of Chopart's amputation, and in the discussion I expressed the opinion that sufficient attention was perhaps not paid after this operation to the position given to the stump. If the stump is left to itself, the powerful extensor muscles found on the back of the leg will inevitably draw the posterior end of the os calcis upward, and then allow the cut tendons of the anterior muscles to attach themselves too far up on the astragalus. I wish to call the attention of the Society to the fact that this patient can flex his short stump very freely, and that when he walks the stump has no tendency to point downwards.

Dr. Charles McBurney then read a paper on

CASES OF KNEE-JOINT EXCISION, WITH REMARKS.

(See page 409.)

Dr. C. T. Poore had excised nine knee-joints in children varying from four to sixteen years of age, and had had good results except in two cases. In one of these the patient died six months after the excision from abscess from disease of the dorsal vertebræ bursting into the lungs; in the other, the child would probably die from chronic brain trouble.

In the first case the consolidation of the bone was firm at the time of death; in the second, union is not firm.

In two cases he had had the same secondary complications. In one case necrosis of a small portion of the external aspect of the femur, in another of a portion of the external head of the tibia. Recovery took place in both patients after extraction of the sequestrum.

He had also experienced trouble from collection of pus in the synovial sac above. In some of his cases there had been more shortening than in Dr. McBurney's case, but he thought part of it was due to atrophy of the limb from disease. He did not think the bad issue in the two cases was due to the operation, but to the general condition of the patient. He had not seen very high temperature in any of his cases after operation. He always suspended the limbs in the after-treatment, because he thought he could take care of his patient better in this way, and it was more comfortable for them.

Dr. McBurney would like an expression of opinion as to the importance of wiring the bones together or introducing nails. He had reached the conclusion that it was not important. It seemed to him that the introduction of wires or nails, even with careful antiseptic precautions, had considerable disadvantages, as shown in several cases in which he had operated. The disadvantage being constant irritation where the wires have been brought out through the skin. The wires, however, might be buried, and the chances taken with reference to their exciting irritation. He thought that the leverage of the leg was too great to allow small wires in soft bones to resist any strain upon the parts, and even where nails had been introduced, as he had understood, they had become loosened long before any strong adhesions had taken place between the bones, except, perhaps, in young patients.

Dr. Lange thought that in using nails coaptation of the surfaces was much more intimate that it would otherwise be, and he also thought that this intimacy of coaptation secured a greater certainty of bony union than by resorting to any other method of uniting the bones. He believed, from the results of those who have resorted to this method more extensively, that the coaptation is so accurate that bony union is secured in a comparatively short time.

He had found in the fourth week after the operation that the nails were somewhat loosened, but still they were so fixed that it required considerable force to pull them out, and even at that period they contributed somewhat to fixation. In case you are obliged to change the dressing the coaptation of the bones which has been secured by nails or wires remains during the change of the dressing much more accurate than when they are treated by measures which keep the coaptation less firm and accurate. This question perhaps is not so important now as formerly, since we are accustomed to use permanent antiseptic dressings where the limb may remain untouched for months, or even longer.

With regard to the advisability of exsection of the knee-joint in such young patients, there is always so much shortening of the limb that he was inclined to the opinion that where exsection of the knee-joint in a child can be avoided it is well to do so, and try to repair the injured bones without opening the joint and searching for tubercular disease, if altogether the case is such as to make this plan of treatment practicable. He had succeeded in this way in one case. In other cases the disease was so extensive that a more extensive operation was necessary. In one case the result was a very good one, and he thought that a better chance was given for the development of the limb than would have been afforded if exsection had ben performed. So far as he knew, the growth of the limb might be shortened six or eight inches, so that entire disfiguration of the patient occurs in this manner.

With regard to prognosis, he thought it was much better in those cases in which ankylosis exists than in those in which fungoid disease is present. He had tried in some cases to obtain more free access to the synovial pouch by making a longitudinal incision as high up as the extension of the articular surfaces. The more fully the parts are exposed and search is made for diseased synovial membrane, the more is one apt to find that small abscesses exist in the capsule and about the joint where cheesy foci exist, which explain the fistulæ that are persistent.

Dr. L. M. Yale referred to a case which had a bearing upon the question of bony union. It occurred about twenty years ago, and was operated upon by the late Dr. Enos, with the result of obtaining apparently bony union. Some time after leaving the hospital, the patient fell, and was brought back, when it was found that the cicatrix had torn like a piece of cloth, and the bones had separated at the line of excision. On examination it was found that there had been partial union of the bone, as shown by what might be called stalactites running from one cut surface into the other, but at the same time the flat surfaces of the bones had united in some places by these bony prolongations, while in other places it had not. Dr. Yale replaced the limb as nearly as possible in the straight position, and the boy made a good recovery with somewhat greater flexion than existed before the receipt of the last injury.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 5, 1881.

The Vice-President Horace T. Hanks, M.D., in the Chair.

Dr. H. J. Garrigues read a paper on

THE REMOVAL OF THE PLACENTA.

The correct title of the paper, he said, was "The Removal of the After-birth," which term included both the membranes and the placenta, and it was also more appropriate from the fact that he did not intend to treat on this occasion of the delivery of the placenta in cases of abortion.

It was now thirty years since Credé had published his views on the treatment of the third stage of labor, and since this original publication he had repeatedly reiterated his conviction of their soundness. His idea was that the placenta should be removed, not by means of traction from below, but of pressure from above. Dr. Garrigues then described the details of Credé's method. He advised that the hand should be placed on the abdominal walls over the uterus after the delivery of the child, and that when it was felt to contract it should be firmly grasped by both hands, with the thumbs in front; when, as soon as the contraction had reached its maximum intensity, the whole organ was to be pressed downward in the direction of the hollow of the sacrum. One contraction was rarely sufficient to expel the placenta. Sometimes this was accomplished at the third contraction, but more usually it was not until the fourth, and it was an error to make pressure between the contractions.

Of late years some of the German authorities had raised objections to the Credé method; their chief criticism being that it was liable to give rise to retention of the membranes. This objection, he thought, was entirely groundless. During the last eight years he had practised the method constantly, and when he was appointed to the Maternity on Blackwell's Island, he introduced it at that institution. He could only say that it had given perfect satisfaction, and that he had never seen any bad results from it whatever. During the last two terms of service at the Maternity Hospital there were 408 confinements. Two of these were cases of abortion, in which the placenta was adherent, and in both he removed it by means of the dull wire curette and forceps. In 6 cases beside these there was retained placenta, and in 6 others the whole or a portion of the membranes was retained. In 6 out of 400 cases, therefore, the Credé method failed to deliver the placenta, a percentage of only 1½. In 4 of the 6, however, there was an abnormally intimate connection between the placenta and the uterine walls; so that there were in reality only 2 cases out of 400 in which it failed, or one-half per cent. In these the placenta was not adherent, but simply retained. True adherent placenta, such as occurred in the 4 cases just mentioned, was very rare; the so-called retained placenta being due, as a rule, merely, to improper treatment. In 6 cases, or one and one-half per cent., more or less large shreds of membrane were retained. In order to remove these, the whole hand was introduced into the cavity of the uterus in one instance; but in the rest this procedure was unnecessary. Credé said that he had not observed any bad effects from the retention of portions of the membranes, and advised that they should be allowed to remain undisturbed. Dr. Garrigues, on the other hand, had seen very serious results follow the retention of membranes, such as alarming post-partum hemorrhage; and, therefore, he thought there could be no question that it was best to remove any retained portions. Where this was necessary, disinfection should always be practised, and he had formerly used a five per cent. solution of carbolic acid for the hands, and a two per cent. solution for washing out the uterus afterwards. Since October, 1883, however, he had employed bichloride of mercury solution, of the strength of 1 to 2000, exclusively.

The great utility of the Credé method, it seemed to him, was due to the fact that it was strictly modelled on the regular course of nature, so that its effect was simply to assist the normal process of completing the act of parturition. After the powerful efforts kept up by the uterus during the second stage of labor, there was, as a rule, some atony of the organ resulting. There was thus, at this time, a call for artificial aid in getting rid of the placenta, and this needed stimulus to spur the uterus on to renewed action was supplied by the compression and pressure applied in the manner Credé indicated. Contraction of the uterine muscles was thus brought about, and Dr. Garrigues now described the two groups of bundles entering into the muscular structure of the organ, the action of the first of which (the concentric ones) was, he said, to bring the fundus towards the os, and of the second (the bundles which had attachments upon the bony pelvis), to draw the uterus down into the pelvic cavity, at the same time that they tilted the fundus forward and the cervix backward. He then went on to say that by means of the compression of the fingers and thumbs of the accoucheur the uterine walls were brought near together, and that the pressure downwards on the fundus drove the organ towards the hollow of the sacrum, while the contact of the placenta against the cervix also tended to open the os.

By shortening the third stage of labor, Credé's method had a direct tendency to prevent *post-partum* hemorrhage. In the four hundred cases referred to, there were but two instances of such hemorrhage of any severity, although in two others there was a slight loss of blood above the normal. In all these cases the hemorrhage occurred before the expression of the placenta was made, and in not a single instance afterwards. When properly performed, the procedure was, undoubtedly, the best means of preventing post-partum hemorrhage.

Inversion of the uterus, which was facilitated by traction on the cord, was promptly counteracted by the Credé method. He had even known avulsion of the organ to be caused by traction. In some cases the *vis a tergo* was so great, when pressure was properly applied, as to expel the whole after-birth completely outside the genitals; and where this did not occur, it was recommended that before withdrawing the placenta the membranes should be twisted into a kind of string. As a rule, however, there was no necessity for introducing the fingers into the vagina (which was liable to be followed by much more serious consequences than before the delivery of the child), and the avoidance of this constituted a part of the modern antiseptic treatment of labor. Dr. Garrigues explained that, contrary to the usual practice on the Continent and in many parts of the United States, he placed the parturient woman on the left side during the second stage (which, he believed, was attended by several important advantages), but said that after the delivery of the child he had the patient turned upon her back, which was the most advantageous position for the delivering of the after-birth.

In Credé's last published communication he had reported that in two thousand cases of labor the average duration of the third stage was four and a half minutes; but in his own cases the average was somewhat greater. It was to be remembered, however, that in Europe the medical attendant in charge at lying-in hospitals re-

tained his position for a number of years, and, consequently, had the opportunity of becoming very expert in all the manipulations incident to the conduct of parturition, while in the Maternity on Blackwell's Island the resident accoucheurs are changed every two months. But, in his opinion, it was altogether immaterial whether a few minutes more or less were occupied in the third stage of labor. The important point was, that from the time of the delivery of the child the uterus should be kept in a contracted condition, and that expression should be made only during the occurrence of the special contractions.

Dr. Garrigues then went on to say that, as the originality of Credé's method had been impugned in certain quarters, he had taken the trouble to look over all the old obstetric authorities that were to be found in the library of the New York Hospital, and found that these could be arranged in three classes. The first spoke of traction only in the delivery of the placenta; and the second, comprising a very considerable number of distinguished names, advised rubbing and pressure over the fundus, through the abdominal walls, in connection with traction on the cord; while a third class, composed of Johnson, Sinclair, and Murphy, who had all been assistants at the Dublin Lying-in Hospital, especially advocated friction and pressure with the hand on the abdomen, which, they claimed, was often sufficient for the delivery, though at the same time they advised traction on the cord. So, therefore, while many English writers, and especially those of the Dublin school, are undoubtedly entitled to some credit in the matter of uterine pressure, it was reserved for Credé to enunciate distinctly the following important points:

First. That uterine pressure is applicable in all cases.

Second. That the uterus should be grasped from all sides.

Third. That it should be squeezed with decided pressure downwards and backwards, in the direction of the pelvic brim.

Fourth. That the cord and placenta, as a rule, should never be touched until after the expulsion.

Fifth. That the fingers should not be introduced into the genital canal.

He then enumerated the advantages of the Credé method as follows:

First. Its certainty of action.

Second. Its influence in exciting uterine contraction.

Third. The prevention of hemorrhage.

Fourth. The prevention of hour-glass contraction of the uterus.

Fifth. The prevention of uterine inertia.

Sixth. The prevention of avulsion of the cord or uterus.

Seventh. The prevention of inversion of the uterus.

In regard to the disadvantages of the old method, he thought it was unnecessary to speak, as they are just the opposite of the points enumerated. There was still another plan of treating the third stage of labor, which was usually known as the Strassburg method, and which consisted simply in the absence of any kind of interference whatever. This had been tried as an experiment, and the results in one hundred cases reported were as follows: In twenty-four cases the placenta came away within the first half hour; in twenty, within the second half hour; in twenty-five within two hours; in eleven, within three hours; in nine, within four hours; in five, within five hours; in three, within six hours; in two, within eight hours; and in one, within twelve hours. In every instance the fœtal surface of the placenta presented first. In two cases hour-glass contraction of the uterus occurred, and in one there was a very decided putrid odor. Dr. Garrigues said that he failed to see a single advantage. The process was not even a natural one, since the recumbent position was unfavorable for the expulsion of the placenta. Among uncivilized nations it would seem altogether likely that the parturient woman, if recumbent during the second stage of labor, would change her position after the birth of the child, and Dr. George J. Engelmann, of St. Louis, in his exhaustive study of parturition among savage peoples, stated that the delivery of the placenta usually followed soon after that of the child, but, if it did not, massage over the abdomen was frequently resorted to. Even among animals it had been observed that an effort was sometimes made to assist nature, and Dr. Sussdorf, in his interesting account of the labor of an elephant, related that after the birth of her offspring, the mother pressed her abdomen with great force against the stake to which she was chained, in order to facilitate the delivery of the after-birth.

In the four hundred and eight labors at the Maternity to which he had referred there was no case of hour-glass contraction, and statistics showed that this occurred much more frequently in cases in which no compression was used than in those treated by the Credé method. In conclusion, Dr. Garrigues said that it was scarcely necessary to point out that it was highly dangerous to leave a placenta in position until it began to stink. While the prudent accoucheur would not allow a retained placenta to remain too long, there was, as a rule, however, no need of haste in making active interference. All that was required was that he should abridge the third stage of labor only to such an extent as to keep his patient from the dangerous consequences liable to ensue from too prolonged inaction.

DR. ALEXANDER HUNTER said that he fully endorsed the conclusions of the author of the paper, and that he would speak upon only one point, which was, the desirability of commencing the uterine pressure just before the delivery of the child. He believed that the uterus should always be allowed to expel the fœtus from itself as well as from the vagina, unless the child is in danger of suffocation. By this early resort to compression the delivery of the placenta was very much shortened, and the danger of post-partum hemorrhage diminished.

DR. ALEXANDER HADDEN thought that intelligence and coolness on the part of the accoucheur were necessary for the proper treatment of the third stage of labor, and that serious consequences were very liable to result from bad management. Among these might be mentioned hemorrhage, septicæmia, and a condition of subacute inflammation. Catarrhal troubles, which rendered the patient an invalid for years, and upon which much of the gynecologist's labor depended, frequently originated, he believed, in this way. During the last twenty-five years he had attended some twenty-three hundred cases of labor, and he had never lost sight of the importance of attending with great care to the delivery of the after-birth. In his last thousand cases

there had been but one death from post-partum hemorrhage, and this fatal result occurred in a patient who was the subject of *purpura hæmorrhagica*. In the removal of the placenta he had been accustomed to depend partly on pressure and partly on traction on the cord, always taking care to see that the uterus was properly contracted (with a distinctly globular outline), and watching the patient for at least an hour and a half after delivery.

As to the production of inversion of the uterus by traction on the cord, as claimed by Dr. Garrigues, he confessed that he was somewhat sceptical. He had always been accustomed to employ traction, though invariably in a gentle manner, and the only case in which he had ever seen any attempt at inversion, was one in which this occurred before any effort at all, by traction, or otherwise, had been made to deliver the placenta. There was profuse hemorrhage, and a cup-shaped depression was noticed in the top of the uterus through the abdominal walls, while through the os the fundus could be felt. Carrying his hand up into the uterus, he restored the partly inverted organ, but found great difficulty in getting the fundus to retain its normal position. The circular fibres of the uterus seemed entirely relaxed, while the active contraction of the longitudinal fibres tended constantly to force the fundus down. By the persevering use of ice and pressure, however, he finally succeeded in securing the normal contraction of the entire organ; up to that time he had believed that traction might cause inversion, but since seeing this case it had seemed to him probable that the inversions which had been attributed to traction might, in reality, be due to entirely different causes. In this instance he believed that the placenta was attached to the fundus, and that the effort to expel it had tended to cause inversion of the uterus. Attachments in this position, he thought, were rare.

Dr. Mary Putnam-Jacobi believed that the Credé method was the only one that ought to be used at the present day, and that it would be superfluous to make any comment on the views expressed in the paper, which were undoubtedly the correct ones. There were, however, one or two theoretical suggestions which she would venture to throw out. The expulsion of the placenta was something which was being prepared for, all through the later weeks of utero-gestation, by the formation of thromboses. Up to the time that the uterus was expected to contract, the circulation of the organ was predominantly venous, since this was most appropriate for its growth. But now, however, it became of an arterial character, as arterial blood alone could furnish the stimulus necessary to produce muscular contraction. Hence the venous blood gradually became cut off by the formation of thromboses at the edges of the placenta, and by the migration of leucocytes, which tended to block up its passage. In cases in which there was a failure of uterine contraction, therefore, it was natural to suppose that there had been an abnormal continuance of the venous circulation, and that, consequently, the necessary arterial stimulus was lacking. The Credé method was entirely philosophical, because the pressure tended directly to diminish the amount of venous blood, and thus assisted nature in continuing the process which she had already begun.

Dr. Paul F. Mundé said that he had, unfortunately, come in too late to hear the paper, but he would nevertheless give expression to a few thoughts which occurred to him in connection with the subject of which it treated. When, thirty years ago, Credé had advanced his views on the delivery of the placenta, it was generally believed that the true method had at last been reached, and that its adoption would entirely do away with all the ills incident to the third stage of labor, particularly the occurrence of post-partum hemorrhage. These anticipations had, however, not been altogether realized. He himself had been taught the Credé method in Germany, and had constantly practised it for a number of years. As a rule, he had been satisfied with it, but occasionally he had found that too rapid expression of the placenta gave rise to uterine inertia and the retention of more or less of the membranes. He had come to the conclusion, therefore, that it was best not to hurry up matters too much, but to allow plenty of time for nature to act. Beginning with the delivery of the child's head, he was in the habit of placing the hand on the abdomen and making gentle friction over the fundus. Before the expulsion of the placenta the latter would be found to reach as high as the umbilicus; but if the uterus extended only half-way between the symphysis pubis and the umbilicus, and was of a well-marked spherical shape, we could be certain that the placenta was no longer in the cavity of the organ. Delivery of the after-birth was not always possible by the Credé method, for in some cases, while the hardness, lobular outline, and reduced size of the uterus, as felt through the abdominal walls, indicated that it was no longer in its cavity, neither did the placenta appear at the vulva. In such cases it was retained in the cervical cavity, and in these instances the cervix was usually of exceptional length. Here it was advisable to make slight traction on the cord, or, what was better, to introduce the fingers, or even the whole hand, into the vagina and withdraw the placenta. If the ordinary precautions of cleanliness were used, he did not think that the latter procedure was attended with the slightest danger to the patient. As he had before remarked, if the placenta were removed too rapidly, it would be stripped, and the membranes left in the uterus, and he thought it was necessary, therefore, that Credé's excellent directions should be followed closely. If properly carried out, the pressure would cause contractions which would result, first in the detachment, and then in the expulsion of the after-birth. Dr. Mundé then went on to say that formerly he had to remove more placentæ by introducing the hand into the uterus than was now the case, and he believed that the more carefully Credé's method was followed up, the less danger there would be of retained placenta.

When the placenta was loose in the uterine cavity, but retained therein by the contraction of the os (the encysted placenta of Barnes), the plan of expression was of no use, and traction on the cord was worse than useless. In such cases it was advisable to secure relaxation of the circular muscular fibres by means of chloroform. There was one point which he was always very particular to carry out, and that was, to examine the placenta and membranes with great care after their delivery, to make sure that the after-birth had come away entire; and if he found that any portion was left, he at once passed his hand, disinfected with an appropriate antiseptic solution, up into the cavity of the

uterus and removed it. He did not believe in leaving the matter to nature, for, while the retained membrane or portion of placenta, might perhaps not do any harm, the danger of evil results was so great that, in his opinion, it was simply criminal not to interfere. Where the hand had been introduced, it was always advisable to wash out the uterus with an antiseptic solution, and he would now employ corrosive sublimate for this purpose. Hot water, he believed, was better than cold, but in order to be of service it ought to be really hot, and there was more or less danger of the temperature being so high as to do injury. In certain cases in which the Credé method had to be kept up for a considerable time, and the necessary manipulations gave rise to more pain than was desirable, he thought it well to follow up the pressure by gentle traction on the cord.

DR. FRUITNIGHT did not believe in a let-alone policy, but thought that as the placenta had fulfilled its function, and, after the delivery of the child, became in a manner a foreign body, it should be gotten rid of as soon as possible. As a rule, the Credé method was undoubtedly the best.

DR. ISAAC E. TAYLOR, after some preliminary remarks on the great care with which the third stage should be managed, spoke of the shortening of the time occupied by it, which had been claimed for the Credé method. This he did not believe was a matter of importance, since the expulsion of the placenta was a physiological process, and there was no necessity for being in a hurry about it. Nature prepared the way for it, and showed us how to act in such a way as to assist her; but improper interference could not fail to do more harm than good. In all his experience, he had not had to introduce his hand into the uterus six times for the removal of the placenta. He used no traction on the cord, but, gently taking hold of it, he passed the fingers up to the cervix, the stimulation of which produced a reflex action which excited the fundus to contract. It was easy to discern to what portion of the uterine walls the placenta was attached, and when this was done, a little modification of the position of the patient would often facilitate the delivery. Thus, for instance, if the attachment was posterior, it would be of service to extend the lower extremities. If the placenta did not come away readily, however, there was not the slightest necessity for hasty interference. If the hand were introduced violently into the uterus, the procedure might be followed by bad consequences, and it was much better to wait for a considerable time before resorting to such a measure. If the after-birth did not come away within twenty minutes or so, there was no harm whatever in waiting one or two hours, if necessary, and nature was generally competent to bring the matter to a successful issue herself. Credé's method, Dr. Taylor remarked, in closing, was not applicable if the placenta was attached posteriorly, looking backward.

DR. RANSOM thought that the best way of delivering the after-birth was to employ gentle traction on the cord, in connection with moderate but firm pressure over the fundus. Out of seven hundred and forty-three cases in his own practice, he had found it necessary to introduce the hand into the uterus to accomplish the removal only in three or four instances, and in all these he found chalky granulations present both on the uterine walls and the placenta. One of these resulted fatally from peritonitis four days after delivery; but he believed that this was due to the fact that, unknown to him, the nurse had been employing hourly vaginal injections. The average duration of the third stage of labor had been fifteen or twenty minutes in his hands.

DR. E. H. M. SELL said that he thought it was not advisable to adhere strictly to any one plan in all cases, but to be guided more or less by circumstances. In the early part of his professional career, influenced by the teaching of Prof. Taylor, he took from half an hour to an hour and a half to deliver the placenta; but more recently the third stage usually occupied fifteen or twenty minutes. Denham, as early as 1800, had given expression to views similar to those of Credé, but it remained for the latter to perfect the method. Personally, however, he would not tie himself down to any one plan. In only one case had he found it necessary to introduce the hand into the uterus. This was after the delivery of a monstrosity, the case being complicated by a short cord, as well as adherent placenta; and he interfered because hemorrhage was taking place. He believed, with Dr. Mundé, that too rapid carrying out of Credé's method was very liable to result in inertia of the uterus.

DR. GARRIGUES said, in bringing the discussion to a close, that it was quite natural that the three methods of which he had spoken in his paper should all have their champions to a certain degree, but he did not believe that any one present would be willing to trust exclusively to the do-nothing plan. All were agreed, he thought, that the delivery of the after-birth was a physiological process, and that our efforts to facilitate it should be in imitation of nature. There might be a diversity of opinion as to how this could best be done, but he had endeavored to show that the different points in Credé's method had precisely the same effects as the natural process. Traction on the cord, however, was not a natural process, and there was nothing in the physiological action analogous to it. If it were used at all, the traction ought to be as gentle as possible, but he himself went so far as to claim that in the vast majority of cases it should never be resorted to at all. In regard to Dr. Hadden's case of partial inversion, he remarked that this kind of paralysis of the portion of the uterine wall to which the placenta was attached was one of the recognized causes of inversion. He had not claimed that this accident was always caused by traction, but he did not doubt that it was sometimes due to it. In regard to the use of hot or cold water for injecting the uterus after the hand had been introduced into its cavity, he said that he preferred the hot, on account of its stimulating effect, although he acknowledged that there was danger of having it at too high a temperature. He was unable to understand how Dr. Taylor could tell when the placenta was attached without introducing the fingers or the hand into the uterus. He entirely agreed with the latter that it was bad practice to resort to early interference of a violent kind in retained placenta. With the Credé method the after-birth, as a rule, came away in a few minutes, but if it did not, it was his practice to wait for at least an hour and a half before introducing the hand into the uterus. He did not think it was right, however, ever to wait until the placenta had begun to decompose.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, April 3, 1884.

The President, R. A. Cleemann, M.D., in the Chair.

Dr. Cleemann made some remarks on the subject of

DIGITAL DILATATION OF THE OS UTERI DURING LABOR.

He had been taught not to dilate or stretch the os uteri with the finger, and for years this early teaching deterred him from making any attempt to supplement the contractile powers of the uterus by assisting in the process of dilating the os. Some time since he was called to attend a primipara, the waters had been discharged the previous day, the pains had continued, but the os uteri was very small and the cervical rim hard and unyielding. He felt called upon to interfere actively, and tried to dilate the os with his finger; it softened rapidly, and in half an hour was sufficiently dilated to allow the head to pass, and delivery rapidly followed. Since that occasion he has tried the same procedure on several cases, and always with gratifying results, the labors being brought to rapid terminations where previously hours had been wasted in weary and painful waiting. The irritable condition of the os, which has been lectured upon as the consequence of such interference, has not been experienced; no injury has resulted in any case. The soft finger can do no more harm, if clean, than a Barnes's or other form of dilator, and there is no danger, as in the case of the latter, of pushing the head aside and converting a vertex into a shoulder or other faulty presentation.

Dr. W. T. Taylor said he had dared to deviate from the teaching of Professor Hodge, and had used his finger to assist the dilatation of the os; but he did not do so if the cervix was irritable or its edge wiry.

Dr. Githens had practised digital dilatation of the os uteri throughout his obstetrical practice, a period of eighteen years. He does not confine it to any class of cases, nor does he wait until after the membranes are ruptured. In any or all cases he finds that a "pain" is accompanied by a contraction of the circular muscular fibres of the cervix as well as by a contraction of the longitudinal fibres of the body of the uterus. The contraction of the circular fibres retards the progress of the labor. The intention of the digital distention is to paralyze these circular fibres, and thus favor the dilatation of the os. In practice this effect is rapidly produced, One or two fingers are swept around the inside of the cervix, the pulp of the finger being next the cervix, and the latter is pulled away from the head. This operation is kept up during the interval between pains; when the pain occurs the finger is withdrawn; the operation is repeated in the next interval. The membranes are not ruptured by this process. The irritable condition of the os, if such exists, is subdued. If the rim of the cervix is wiry and thin, or hard and thick, it softens and yields; the cervix and vagina, if hot and unyielding at first, become cool and pliant; cervical tears are almost entirely avoided, and the time, pain, and exhaustion of the labor are reduced to a minimum. The process is useful in every case of labor throughout the first stage.

Dr. Philip M. Schiedt practises digital dilatation largely. His patients say they recognize the assistance it gives them, and in subsequent labors ask him to help them. By the great shortening of the first stage of labor resulting from this method, the use of the forceps is frequently avoided.

Dr. Parvin said he would be sorry to see digital dilatation adopted as a rule for all cases. He thinks it shortens labor by increasing the uterine contractions, and not by dilating the os. Voluntary efforts at bearing down are not needed during the first stage, they are dangerous rather than helpful. The method may be useful in some cases after the rupture of the membranes, which is the natural dilating agent. There is also danger of septicæmia from germs on the fingers. He does not think the fingers so good a dilator as Barnes's dilator, because they do not press equally on all sides of the os, but only on one point at a time, and thus cause an unequal thinning, with danger of laceration. He thought the danger of a change of presentation by the use of Barnes's dilator very slight. He would prefer a mechanical dilator to the finger whenever dilatation was necessary, but thought something ought to be left to nature. Any sort of interference carries a possibility of danger.

Dr. Elliott Richardson thought that there was a possible danger of rupturing the membranes.

Dr. R. P. Harris remarked that one point had been overlooked. Why does the os not dilate easily when the head is the dilating agent? It is because it is a round surface over which the cervix does not slide easily. On the contrary, the finger is applied at successive points. One benefit of the method is that any change or danger is at once detected. The method should not be used indiscriminately, and we should not interfere unnecessarily.

Dr. Cleemann would not recommend the method in every case of labor. He has resorted to it in cases in which there has been early rupture of the membranes and the assistance of the bag of waters has been lost. In a recent case, he saved a patient hours of suffering, and the os was not bruised or injured in any way. The sight of any instrument causes the patient much anxiety, and the exhibition of the Barnes's dilator, and the water, syringe, etc., causes nervous excitement. The bags sometimes burst, and thus give the patient a terrible shock with the added discomfort of the escaping water or air. He has always carried them, but does not like to use them.

EXANTHEMATOUS DISORDERS IN THE PUERPERAL STATE.

Dr. Parvin had recently had an experience of the invasion of measles and scarlet fever in the obstetric wards of the Philadelphia Hospital. In the first case in which measles occurred, he did not think that the full term of pregnancy had been reached. Authorities state that premature labor is usually caused as a result of the high temperature of the exanthematous fever. One patient had septicæmia in addition, but recovered. The infants were not affected. In one case, soon after labor the temperature rose to 103°, and the patient was sent to the fever ward. At the second visit a slight rash was observed, which subsequently proved to be scarlatina. Desquamation was very abundant. Albuminuria was very marked on the tenth day. Rheumatic pains were also felt. The patient recovered. The child remained well. Children have been born with measles, but he did not know of such an experience with scarlet fever.

Dr. W. T. Taylor some fifteen or twenty years ago,

had reported in THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, 1853, a case of congenital smallpox. The mother had some febrile symptoms and pain in the back, and the child had the disease. He had a case of scarlet fever in a mother two days after labor; it proved fatal in two days; the child lived.

CORRESPONDENCE.

DOWNWARD DISPLACEMENT OF THE TRANSVERSE COLON.

To the Editor of THE MEDICAL NEWS.

SIR: An article with the above title, from the pen of Dr. C. H. Thomas, of Philadelphia, appeared in the *Boston Medical and Surgical Journal* of January 3, 1884. The writer states that the lesion seems to be of rare occurrence, and that Dr. Formad, of Philadelphia, in a series of autopsies numbering over two thousand, had not observed a similar case. Further, Dr. Formad, after thorough examination of the literature of intestinal lesions, had not met with any record of misplacement of the transverse colon.

From the fact of Dr. Thomas meeting with three cases, it would be fair to infer that the lesion is not as rare as has been supposed. In an autopsy of my own, made January 17, 1884, on a mulatto woman, aged sixty, who died of consumption two days previously, the "arch of the colon was low down in the iliac and hypogastric regions." Delafield mentions that it may be lower than the umbilicus; Orth, that it is sometimes depressed in the form of a loop, which may extend even into the pelvis; and Rokitansky, that it may descend into the hypogastric region. Turner (*Human Anatomy*, Edinburgh, 1877, p. 714) uses the following language: "Owing to the length of the transverse meso-colon, which forms its peritoneal attachment, it not unfrequently undergoes some change in its position, and may hang downwards toward the pelvis, or be elevated in front of the stomach or thrown to the right or left side. This tendency to displacement of the transverse colon should be kept in mind in the diagnosis of diseases of the abdominal viscera." Leube (Ziemssen's *Cyclopædia*, translation, vol. vii. p. 342) says that it may sink below the umbilicus. Charles Bell, and Sharpey and Quain speak to the same effect. So also Harrison (*Anatomy*). Bichat remarks the mobility of the transverse colon, which sometimes permits displacement. Cruveilhier says, "It is not rare to see it at the level of the umbilicus or even in the hypogastric region—even in the pelvis." He regards the corset as a main cause in women of the displacement downwards. He recites a case of an old woman in whom the arch descended perpendicularly, parallel with the ascending colon, passed into the pelvis, and then ascended to the left.

The *Index Catalogue of the Library of the Surgeon-General's Office* indicates several authors, under the head of colon anomalies. One case is by Maldern (*Midland Med. and Surg. Reporter*, i., 1828–9, p. 53). The transverse colon passed downwards to the right iliac region, and then ascended to the left hypochondriac. The displacement was not recognized during life. Esquirol (*Journ. Gén. de Méd.*, lxii., 1818, p. 341, and lxiii., 1818, p. 176) contributes cases of the same sort in the insane. In one, the transverse colon descended perpendicularly to behind the pubis; in a second, a similar variation; in a third, the same; in a fourth, it reached to near the pubis; in a fifth, it reached quite to the pubis; in a sixth, the same; in a seventh, nearly to the pubis; in an eighth, to the pelvic cavity. Some of these were women, some were men. Esquirol thought that the phenomenon had not previously been noted. He found that the arch was in such cases usually empty. He adds that the insane people in whom he found the lesion were mostly affected with melancholia, and often complained of epigastric pain, likening it to a band around the hypochondria; the stools were generally bad. He did not, however, think that these symptoms explained the misplacement of the colon. Erdmann (*Archiv für Med. Erfahr.*, Berlin, ix., 1806, p. 98) mentions the occurrence of this lesion, and says that he found it very often ("sehr häufig bei Sectionen"). He gives cases, and says that he finds it mostly in women, and attributes it then to their wearing "stays." In his three cases, he found also a perpendicular direction of the stomach.

Roth (*Pathologia intestini coli*, Erlangen, 1803); Vater (*Diss. de situ naturali et præternaturali intestini coli*, Wittemberg, 1737); Leuringk (*De morbis a situ intestinorum crassorum pendentibus*, Goettingen, 1756), are said to have noted the displacement. Roth does give a case of displacement downward to the pubis, of the colon distended with flatus and feces; the case was narrated to him by another physician. The other two authors I have not been able to see.

Sylvius (opera, 1679, p. 185) mentions under the caption *De Variis Intestinorum Doloribus*, the deviation of the colon to the umbilicus and even sometimes to the bladder. Morgagni (*De sedibus et causis morborum*, translation, London, 1769, vol. ii. p. 125) in his thirty-fourth letter says:

"When that part of the colon which generally runs in a transverse direction to the direction of the body, and lies in contact with the stomach, is not really in that place, but is so remarkably inflected downward, there is no doubt but those persons must err, who deny that this part of the colon is seized with pain, by reason that the pain and torture do not run across the upper part of the belly, like a belt . . . and that what Sylvius has warned us of, does, in fact, frequently happen to the colon, not a few of the observations, both of Valsalva and of mine, which have either been already proposed, or are to be proposed hereafter, will confirm; although I have not had, nor shall have, occasion to take notice of, in these letters, all the bodies in which I have found it thus; for it is long since that I began to observe this variation, even before I happened to light on this passage of Sylvius, as the second of the adversaria (see Morgagni, adversaria anatomica, 1762, p. 33) will demonstrate . . . In those persons likewise, in whom the stomach is much dilated, and the liver enlarged in its size, that transverse part of the colon which lies under these viscera must be lower in the same proportion as they are enlarged. Add to these such causes as depress the stomach, and with it the colon, as I have seen it happen in a young man of Venice, from a very irregular inflexion of the spine. But besides diseases, there are also naturally different constitutions of bodies, and in these different constitutions different situations of the colon."

I have quoted so fully from Morgagni, because of his well-known erudition and close and ample observation.

This research might be extended, but sufficient has already been given to show that the downward displacement of the transverse colon is not so infrequent, but that the fact of its occurrence should ever be kept in mind in abdominal diagnosis; even of hernia in which this colic arch sometimes takes part.

Very respectfully yours,

D. S. Lamb, M.D.,
Army Medical Museum.

Washington, D. C., March 31, 1884.

A YEAR'S WORK IN OVARIOTOMY.

To the Editor of The Medical News.

Sir: I am bound to say that Prof. Goodell is right in pointing out that Dr. Sutton's words are likely to give rise to misunderstanding. Dr. Sutton stopped with me here for about three months, and I don't know whether or not he saw me remove large tumors with extensive adhesions. It would be a matter of chance anyway, for cases nearly always go in "runs." In order that the nature of my work may not be misunderstood, kindly allow me to say that last year I removed eighty-two tumors of the ovary and parovary, with only two deaths. Two of these were very small dermoid cysts. The remaining eighty had an average weight of about twenty-seven pounds, the largest being about one hundred and twenty pounds, and the smallest eleven pounds. Twenty-seven of the cases are noted as having "extensive adhesions," nine "being universally adherent," and all of these twenty-seven recovered.

I am yours respectfully,

Lawson Tait.

Birmingham, March 26, 1884.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

Congress and Public Health.—Mr. Beach, of New York, by direction of the Committee on Public Health, on April 1st, reported back with an amendment the following resolutions on the adulteration of food, drink, and medicine:

"*Resolved*, That the Committee on Public Health be authorized and directed to inquire into the truth of said alleged abuse, and to report to this House the result of their investigation at as early a day as practicable; and if it shall be shown that such practices exist, then to suggest or recommend in their report what further legislation, if any, is necessary to correct the wrong. And that they may more effectively do their work, be it further

"*Resolved*, That said Committee be, and they are hereby, empowered to send for persons and papers, and to employ such chemical and medical experts as they may deem necessary to carry out the aim, end, and object in view."

The amendment of the Committee was as follows:

"Strike out the words 'and to employ such chemical and medical experts.'"

The resolution gave rise to a prolonged discussion, in which Mr. Brown, of Indiana, Mr. Cox, of New York, and Mr. Reagan, of Texas, opposed the resolution as unnecessary legislation, while Messrs. Beach and Parker, of New York, and Mr. Wait, of Connecticut, favored immediate and favorable action. A motion to further amend the resolution, by limiting the expenditure for such investigation to $1000, was made by Mr. Kasson, of Iowa. Mr. Cox moved to lay the resolution on the table, which was lost. Mr. Beach then moved the previous question, and accepted the amendment of Mr. Kasson. Both amendments were agreed to and the question upon adopting the resolution as amended was taken. No quorum voted. A lively discussion followed, and Mr. Cox moved to recommit the resolution to the Committee on Public Health. Mr. Beach, Chairman of that Committee, moved to lay the motion to recommit on the table. A vote was taken and the motion lost. The question then recurred upon the motion to recommit, which was agreed to by a vote of 117 to 116.

A Home for Disabled Sailors.—Mr. Finnerty, of Illinois, introduced, in the House, a bill for the purchase of ground at Chicago for a home for disabled and indigent sailors of the navy and merchant marine, which was read a first and second time, referred to the Committee on Naval Affairs, and ordered printed.

The National Board of Health.—Mr. Frye, of Maine, presented in the Senate the petition of the New York Committee for the Prevention of State Regulation of Vice, praying that the jurisdiction and powers of the National Board of Health be specifically defined and limited. Referred to the Committee on Epidemic Diseases.

Quarantine Station at Cape Charles.—Mr. Libbey, of Virginia, on March 29, presented in the House resolutions adopted by the Council of Norfolk, Va., and by the merchants and manufacturers of Norfolk, and the Norfolk and Portsmouth Cotton Exchange, recommending the establishment of a national quarantine station at Fisherman's Inlet, Cape Charles, which were severally referred to the Select Committee on the Public Health.

The Secretary of the Treasury received, through the mayor of Portsmouth, Va., on the 4th inst., a set of resolutions adopted by the Common Council of Portsmouth, recommending the reëstablishment of the quarantine station which was in operation last year at Fisherman's Inlet. Surgeon-General Hamilton also received a copy of the above-mentioned resolutions.

Medicinal Plants.—Mr. Morse, of Massachusetts, presented, in the House, the petition of the Massachusetts Pharmaceutical Association asking for an appropriation for the introduction of foreign medical plants, and for the protection of domestic medical plants.

Not Foot and Mouth Disease.—Dr. Salmon, Veterinarian of the Department of Agriculture, has returned to Washington from Kansas and other States, where, by direction of Commissioner Loring, he has been investigating the alleged outbreak of foot and mouth disease, and has made a preliminary report to the Commissioner of his investigations. In conclusion, Dr. Salmon declares that the recent outbreak is attributable to local conditions, and that no single symptom of contagious foot and mouth disease has been or can be shown.

DR. ALFRED STILLÉ.—It is stated that in the early part of next month, immediately after the close of the winter session, Dr. Alfred Stillé will tender his resignation as Professor of the Theory and Practice of Medicine in the University of Pennsylvania, after an incumbency of twenty years.

Five years ago Dr. Stillé offered his resignation, but at the request of the Board of Trustees he withdrew it.

It is understood that Dr. Pepper will be elected to the chair vacated by Prof. Stillé.

A life-size portrait of Prof. Stillé has been painted by Waugh, by order of the students of the Medical Department, and will be presented to the University at the ensuing commencement.

NEW YORK NEUROLOGICAL SOCIETY.—At the Annual Meeting of this Society, held on the 5th inst., the following officers were elected for the ensuing year:

President.—William J. Morton, M.D.

Vice-Presidents.—Drs. C. L. Dana and G. W. Jacoby.

Recording Secretary.—Dr. E. C. Wendt.

Corresponding Secretary.—Dr. W. M. Leszynsky.

Treasurer.—Dr. E. C. Harwood.

Councillors.—Drs. E. C. Seguin, L. Weber, T. A. McBride, W. R. Birdsall, and Graeme M. Hammond.

GARFIELD MEMORIAL HOSPITAL.—In the notice of this hospital in our last issue, the name of Dr. J. Ford Thompson, as one of the attending surgeons, was accidentally omitted.

A MARINE HOSPITAL FOR NEW YORK.—The Committee on Commerce of the House has reported favorably the bill to provide for the purchase of the Seamen's Retreat, in Middletown, N. Y., at a cost not exceeding $280,000, and the use of the same for the purposes of a marine hospital at the port of New York. In making this report the Committee says its enactment would do no more than put the port of New York on an equal footing with respect to marine-hospital service with ports of less commercial importance. It says that New York is the only seaport city in the United States with a large population which has not been provided by the General Government with a marine hospital.

THE DWIGHT LIFE INSURANCE CASE.—A telegram from Norwich, N. Y., states that on the 2d inst. the case of exceptions of Dwight against the Germania Life Insurance Company, was settled before Judge Follett, preparatory to revision in the General Term. On the next day the Ætna Life Insurance Company, of Hartford, which was a member of the pool to resist payment of the $256,000 insurance on Colonel Dwight's life, paid his policy in that company, amounting to $10,000. This is the third company which has paid its obligations.

THE MEDICAL ASSOCIATION OF GEORGIA will hold its annual meeting at Macon, on the 16th of April.

ILLINOIS STATE BOARD OF HEALTH.—The regular quarterly meeting of the Illinois State Board of Health will be held at the Grand Pacific Hotel in Chicago, beginning Thursday, April 17.

At this session candidates for certificates will be examined, both non-graduates, who must undergo an examination upon their preliminary education, as well as in the usual branches of medical study, and also graduates of colleges which have not fully complied with the schedule of minimum of requirements adopted by the Board in 1880, and in force from and after the session of 1882–1883.

ALBANY MEDICAL COLLEGE.—At the annual commencement, held March 5th, the degree of M.D. was conferred on forty-three candidates.

MEMPHIS HOSPITAL MEDICAL COLLEGE.—This institution held its fourth annual commencement on the 29th of February, and the degree of M.D. was conferred on twenty-three candidates.

THE SOUTHERN MEDICAL COLLEGE held its commencement exercises at Atlanta on February 25th, and thirty candidates received the degree of M.D.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending March 29th indicate that inflammation of the brain and pneumonia have increased, and that remittent fever, inflammation of the bowels, tonsillitis, and bronchitis have decreased in area of prevalence.

Including reports by regular observers and others, diphtheria was reported present during the week ending March 29th, and since, at ten places, scarlet fever at twenty-four places, and measles at eleven places.

OBITUARY RECORD.—DR. HALL DAVIS, of London, died on March 19th. He has long been well known as an obstetrician, and is the author of several contributions to the *Transactions of the Obstetrical Society*, of which he was an Honorary Fellow and formerly President.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 1 TO APRIL 7, 1884.

BAILY, ELISHA I., *Colonel and Surgeon.*—Ordered to report to the Commanding General Division of the Pacific for duty as Medical Director of that Division and of the Department of California. —*Par. 4, S. O. 78, A. G. O.*, April 4, 1884.

SUTHERLAND, CHARLES, *Colonel and Surgeon.*—To be relieved from duty in Division of the Pacific, and to report to the Commanding General Division of the Atlantic, for duty as Medical Director of that Division and of the Department of the East. —*Par. 4, S. O. 78, A. G. O.*, April 4, 1884.

WOODHULL, ALFRED A., *Major and Surgeon.*—Granted leave of absence for twenty-two days, to take effect about April 6, 1884. —*Par. 13, S. O. 72, A. G. O.*, March 28, 1884.

STERNBERG, GEORGE M., *Major and Surgeon.*—Ordered to be relieved from duty in Department of California, and to report to Commanding General Department of the East for assignment to duty.

MOSELY, EDWARD B., *Captain and Assistant Surgeon.*—Ordered to be relieved from duty in Department of the East, and to report to the Commanding General Department of the Columbia, for assignment to duty.—*Par. 4, S. O. 78, A. G. O.*, April 4, 1884.

WILCOX, TIMOTHY E., *Captain and Assistant Surgeon.*—Ordered to be relieved from duty in Department of the Columbia, and to report to the Commanding General Department of the East for assignment to duty.—*Par. 4, S. O. 78, A. G. O.*, April 4, 1884.

WHITE, ROBERT H., *Captain and Assistant Surgeon.*—To be relieved from duty at U. S. Military Academy, West Point, N. Y., August 28, 1884.—*Par. 7, S. O. 74, A. G. O.*, March 31, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLIV. SATURDAY, APRIL 19, 1884. NO. 16.

ORIGINAL LECTURES.

AN ADDRESS

DELIVERED TO THE MEDICAL CLASSES OF THE UNIVERSITY OF PENNSYLVANIA,

ON WITHDRAWING FROM HIS CHAIR, APRIL 10, 1884,

BY ALFRED STILLÉ, M.D., LL.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE.

GENTLEMEN: The lectures which, twenty years ago, I began in the University, I have now concluded. I have contributed, according to my ability, to the store of useful knowledge from which your predecessors, for more than a century, imbibed professional instruction. Everyone who, in his turn, comes to occupy a position such as I have had the honor to hold, is ambitious of deepening, and widening, and purifying the stream of knowledge, and, for such little time as the rush of events permits, of being held in remembrance as one who did not labor altogether in vain.

In entering upon the duties of this Chair, I was not altogether in my novitiate as a teacher; yet I felt that my task was one of exceptional responsibility, and to the very last this impression, instead of becoming lighter by familiarity, has grown more serious and profound. I have never for a moment been able to put away from me the impression that according as I discharged or failed to discharge my duties conscientiously would be my responsibility for the lives and health of those who were to become the patients of my pupils.

But no man lives up to his ideal. The further he advances in learning and experience, the higher will his ideal rise, and at the end of his career it will appear to him, more than ever, unattainable; and it must be so, for knowledge is infinite.

The one principle that has shaped and governed my instruction was to oppose fact to theory; to build up the walls of your education securely with the one hand, and with the other to defend you against the intrusion of hypothesis and unsubstantial theories, the most dangerous of all your enemies, because the most seductive to the young and ardent mind. I have often thought that the progress of knowledge would be more rapid, as well as more steady, if it were only possible to divide the speculative men from the practical, leaving a free field to the former wherein to manœuvre their phantom squadrons, and to the latter an equal opportunity of cultivating in peace the fruitful furrows ploughed by observation and experience. But such an expedient would be opposed to the practice of mankind, which also has the sanction of divine wisdom, to let the wheat and the tares grow together until each has brought forth its proper fruit, when the one can be garnered, and the other destroyed.

Well convinced that time never fails to do justice upon the false and fanciful, I have forborne to make that vivisection of them without anæsthetics, which reason and instinct suggested, and have devoted whatever knowledge and skill I possessed to the simple, if difficult, task of knowing and curing diseases. I have striven, in season, and perhaps out of season, to impress upon you that medicine is, first of all, an art, but an art that can only be successfully practised when the physician is able to recognize the individual diseases he must meet with in practice, and distinguish from one another those which are similar in appearance, but unlike in nature. This subject I would fain have had time and opportunity to illustrate by a detailed study of the history of medicine, and by showing you what no medical historian has yet elaborated, the pregnant truth that the real links of the historical chain are, above all, the practical men, the foundation of whose teaching was clinical; and that theorists in every age have been stumbling-blocks in the road of progress, or else the chains, the fetters, and the gags of those who, under proper guidance, would have worked for nature and for truth.

I have endeavored to keep before myself and before you, the great truths that in medicine whatever is not subsidiary to diagnosis and therapeutics is unessential if not superfluous; that it is quite as necessary for the physician to know when to abstain from the use of medicine as it is for him to prescribe when medication is necessary; that he must, as far as possible, see the end of a disease from its beginning; that he must never forget that medical art has a far higher range and aim than the prescription of drugs or even of food and hygienic means, and that when neither of these avails to ward off the fatal ending, it is still no small portion of his art to rid his patient's path of thorns if he cannot make it bloom with roses. Such knowledge not only quickens the patient's faith but confirms the physician's also, because he knows the limits of his power, and is neither deceived himself nor deceives others. The issues of life and death are not, indeed, in human hands, yet the physician, with his finite means, can sometimes render harmless the thunderbolt that threatens destruction. The power that permits death and the manifold causes that produce it has also given to man his love of knowledge and the intelligence to apply it for overcoming evil, and he has likewise implanted in us a conscience that will approve or condemn us as we use those gifts for the welfare or the hurt of our fellow-men. Sooner or later every one of us must sit in judgment on the conduct of his life. We cannot escape self-questioning. We must ask ourselves whether the talents we have received as natural gifts or developed by labor, have grown and multiplied as they should have done, or whether, at the end of our career, we have nothing more to show than the original handful of seed, grown hard and dry, and perhaps mouldy in our unprofitable possession.

To produce a harvest of knowledge that shall be worth gathering, demands at least as much labor and vigilance as the crops that minister to our material wants. In the earliest springtime of life the soil must be thoroughly

prepared for the seed, and the seed itself must be of the best quality. Education should begin from the very cradle, and in early life the habit of observation acquired which is of inestimable value in every pursuit. Then, if the child be destined for a professional life he should be systematically trained, and more and more strictly as he grows older, towards the field of knowledge he is destined to occupy. Thenceforth he must begin to fill his own treasure-house with the fruits of study and observation, not trusting wholly to his memory, which is unfaithful, but recording, from time to time, if not day by day, all that is worth preserving. He should never forget that medicine, like all knowledge, has a past as well as a present and a future, and that in that past is the indispensable soil out of which improvement must grow. He should remember, too, that however closely related the several branches of medicine are to one another, each one in its turn is best learned by an almost exclusive devotion to it for a time, and when his barns are filled to bursting with his harvest, let him not forget that the grain has still to be winnowed. His fan must be in his hand to purge the threshing-floor of the dead, the unessential, the hypothetical, the fanciful, and, above all, the false. In all things truth must be his object, his inspiration, and his guide.

You have fallen upon a time in which medical knowledge far exceeds in amount and variety that of any previous era. The measure of it is most readily apprehended when we consider the extent of the medical literature of the day, and, in some respects, its superiority over that of any previous era. It is perhaps as distinctly indicated by the improvement of medical periodical literature as by any other sign. That it still leaves much to be desired is very true; but in every direction indications may be found that it is gaining in seriousness, dignity, solidity, and energy. Hardly less noticeable is the tendency, at least, of most of our medical colleges to recognize the need of a higher standard of education, while in a few, including the University, actual progress has been made by lengthening the period of professional training, and enlarging and perfecting its laboratories and clinical work. All of this is well, is praiseworthy, is hopeful. But it is not all that is necessary. One thing, at least, is lacking in nearly all of our colleges, and in the few where it exists it is in a formal and merely embryonic state, a promise rather than an achievement. I allude to the preliminary or entrance examination. This was one of the watch-words of the American Medical Association at its organization in 1848. In that body, and in the local medical societies that have concerned themselves with medical education, it has yearly been echoed and reëchoed until in the ears of many it has become a mere phrase without practical meaning. And yet, in truth, it lies at the foundation of all radical improvement in our educational system, for it needs no argument to prove that the merely medical education of otherwise uneducated young men will never elevate or dignify the medical profession.

If the nature of medical science and art is considered, it becomes plain that to embrace them a greater variety of knowledge, and a greater skill in the exercise of the mental faculties, are required than is demanded by any other professional pursuit whatever. Hence it is that in older countries than our own, where education is better understood and more easily managed, because managed by more competent men than with us, the laws prevent all unqualified persons from becoming members of the medical and, indeed, of every liberal profession. It is there universally understood that no one can be qualified, even to enter upon the study of medicine, unless he has been trained in the classics, in mathematics, and in natural science. There it is taken for granted that no one destitute of classical education can appreciate either the spirit of modern medical literature, in the best of which the wisdom of the ancient world survives, or the value of doctrines, descriptions, precepts, and practices which, though apparently of modern origin, take their rise in the remotest periods of medicine; or the significance of words now in daily use which reveal only to the etymologist their essential and recondite meaning. In a word, it is taken for granted that no man can become a physician in the best sense of the word unless he is also a scholar, that the training of the mind which makes him one, also best enables him to form clear notions of things as well as thoughts, and to arrange his ideas in so orderly a manner that, whether for his own use or for the instruction of others, he will always find his knowledge ready and efficient. But that is a part only of the value of a liberal education to a physician. Hardly less valuable—and if estimated not by its material results, but by the mental and moral satisfaction it ensures—not less, but much more, valuable is it to the physician, as it is to every other man whose pursuits are as absorbing, as exacting, and as exhausting—is the culture of some extra-professional field of knowledge. In the hours of rest he may snatch during his busiest life, and in the years of repose that he looks forward to in the waning of his life's evening, he will then never be without the recreation of reading that refreshes his weariness more than idleness, and quickens his faculties by varying their exercise. Every young physician must, indeed, begin his career chiefly among the vulgar and illiterate, but in due time, and all the sooner the better he is prepared for it, he will enter the circle of the intelligent, the educated, and the refined, and then, if he is a mere dispenser of drugs or brandisher of instruments, he will fail to gain their esteem as a man, even while he commands their employment of him as a helper in their emergencies. But if he is a man of liberal education, of cultivated intelligence and taste, and has that large humanity which makes him feel instinctively that his patients are not diseases or injuries, but suffering human beings who may be influenced by psychical as well as by physical agencies, he will learn that mental medicine is often more potent than drugs, and that if in his therapeutics he has not included this agency, he lacks one-half of the power he ought to possess.

Some one may object, perhaps, that the picture I have drawn is an ideal one, and that young men who are educated in medicine cannot often be expected to reach it. Nevertheless, a true ambition would be degraded if it did not set before itself the highest possible attainment, if it did not feel dissatisfied with any system that fenced in its strivings and dwarfed its ideals. But true ambition is rational and not quixotic. It feels that its discontent with the present and its striving towards a better time to come must be subordinated to the laws that govern development in all living things.

When an institution, be it political, social, or educational, is discovered to be no longer adapted to the actual condition of a people, it can be safely modified only in accordance with the peculiarities of the people for which it was established. All history teaches the folly of supplanting it by another institution which was not made for the place or time, but was constructed according to some abstract notion of its usefulness and fitness. It is like ready-made clothing, which is suitable for the average man only, and can never perfectly fit any individual man. The mental qualities of young men are as various and unequal as their complexion, their stature, or their weight; and it can as little be expected that the same system of education will be adapted equally well to all, as that the uniforms from an army sutler's stock will fit becomingly or comfortably every soldier who is to wear them. And yet, practically, such uniforms *must* be worn, and as we very well know their defects do not prevent their wearers from bravely fighting and winning battles. In like manner the systematic education of professional men is no less necessary, and although it suits no one perfectly, it suits all well enough in the battle of life. The individual's education in common can never be the best; but it can always be improved, always made to suit a progressively increasing number. In proportion as the students who come to be clothed intellectually attain to a greater elevation and quality of mental development, the methods of education should be expanded to fit their intellectual height and breadth. So shall they no longer present the sad spectacle of manhood in the jacket and pinafore of childhood, or the ludicrous one of childhood tottering and stumbling in the garments of maturity.

Meanwhile, let us not expect nor attempt abrupt changes. The defect of all reformers is impatience. They insist that, because a principle is intrinsically true, it should forthwith be put into practice; that because a practice is right it should be enforced upon every one. It is not in this manner that good ends are reached, either by nature or by mankind. To take the most familiar illustration: religious doctrines and precepts have never yet leavened the whole of humanity, and crime and its punishments abound in nations that claim to be governed by the highest moral principles. The perfect law of right is opposed by passive ignorance, and moral progress by the tendency to wrong. Only inexperienced and impractical dreamers expect good to flow spontaneously and immediately from evil, or to see a defective system that has the vantage-ground of age swept away as soon as one that is esteemed better is ready to take its place. Such are apt to be the mistakes of those who take a microscopic view of things, whose vision is bounded by the narrow circle of personal relations and interests, and who forget that the questions to be solved are as wide as the whole profession of medicine, and to the end of time will involve dissident if not antagonistic opinions. But if it is impossible, upon a very close view of a subject, to see all of its parts and their relations to each other, it is equally impossible to do so if we take a standpoint above the clouds, where, if we have a wider field of vision, it is a very indistinct one, and where, if the atmosphere is clear, it is also so cold as to freeze humanity out of medicine. It behooves us to remember that medicine is, above all else, humane as well as human; that its beginning, middle, and end is to relieve suffering, and that whatever is outside of this may indeed be science of some sort, but certainly is not medicine.

In one form or another, the doctrine has come down to us from a remote period, *Ars medica tota est in observationibus*—the art of medicine is founded on experience alone. It is the business of science to explain what experience has established; but it is not the primary business of science to observe and connote facts. That is the function of rational empiricism. The application of the results of observation to definite ends constitutes an art. The explanation of those results, *i. e.*, the act of bringing them under some general law or principle, is a function of science. But whether science explains or fails to explain the art, the art is neither more nor less perfect as an art, any more than the eye was less perfect than now in its power of seeing before the structure of the organ or the laws of optics were discovered. Art is inherent in the nature of things and in man's mental constitution. Science is an artificial method designed to generalize the results of observation and experience. There was an art of painting and of sculpture before the laws of proportion and color were understood; and it need hardly be added that if Michael Angelo and Titian rivalled Phidias and Appelles, it was not because the former were better acquainted with the laws of proportion and harmony in form and color. There was an art of rhetoric before the laws of language were discovered; an art, and a science too, of chemistry before the atomic theory was invented; and there was a culinary art, and is at this day, which in its perfection makes ridiculous the laws that chemistry and physiology have promulgated for its government. There is also an art of medicine which no less completely eludes, or as flatly contradicts science, by means of empirical facts, and gives the palm to sagacity and common sense over laws formulated by experiment, and proclaimed with the conviction and imposing solemnity of a new delivery of the decalogue.

I do not make this attempt to show you whereabouts lie the quicksands that may engulf your most cherished hopes, and the rocks upon which they may be dashed, without knowing how prone the youthful mind is to be led astray by false lights, and how confident it feels of passing safely across the dangerous period of life. Unfortunately, the danger is either not seen at all, or is not regarded as danger, and the self-deceived physician, unconscious of his error, becomes an example, instead of a warning. But my object is not so much to convince your judgment, as to lead you to pursue studies that will lessen the risk of your falling into error. My plea for medical history is to induce you to examine it for yourself, being persuaded that you will learn from it that the unity and continuity of medical art have been maintained, not by theories of disease and of medicinal action, that have chased one another like jack-o'-lanterns along the road of time, but by the facts of observation honestly and laboriously accumulated from the beginning until now. This was the theme of a lecture that I delivered nearly forty years ago, and all these years of experience and study have so confirmed me in its truth that now, in this, my last public utterance, I cannot refrain from handing it over to you as the sum and substance of my teaching and the best legacy I can bequeath to all my pupils.

Nearly half a century ago, I was about to emerge, as some of you are now, from the chrysalis state of undergraduate. Surely, no butterfly sees the world brighter before it than this fledgling of medicine. How radiant and fearless is the spirit of youth when we stand upon the hill-top of hope, and seem to embrace the universe in our horizon. The freshness of the morning is in our limbs; the heart's fountain gives out only pure waters; our eyes glow as we turn eagerly to the rising sun, and "From mount to mount through Cloudland, gorgeous land!" we behold the peaks that we feel predestined to surmount. Upon the mist that veils the sun from us (and we thrill as we behold it) is projected a living picture of ourselves, but of gigantic proportions; and as we salute in it the prophetic image of our future greatness, it seems to return the salutation with the "All hail! that shall be king hereafter!" . . . . But the sun has risen to high noon; it has long ago dispelled the mist and its delusive phantoms; we have been wayfarers on the highway of life, foot-sore and weary, and perhaps soiled by its dust; possibly we may have been carried forwards in luxurious chariots; but never, *never*, we may be sure, have we gained possession of that estate in Cloudland which to our youthful eyes seemed so sure an inheritance. Even if we seized the golden apples, and for their possession overcame as fearful foes as the dragons that watched the garden of the Hesperides, too often we have left behind us the appetite that made us covet them, and they seem to turn to ashes on our lips.

Professional life, like every other, is a life of mingled joy and sorrow, of success and failure, of rewards and disappointments. The vastness and variety of the numerous departments of medicine, the nobleness and beneficence of its aims, fill the student who is worthy to pursue it, with perpetual admiration; and, as he masters each new field of research, inspires him with an enthusiasm which hardly any other study is so well fitted to excite. His confidence increases as he proceeds, and he is so sure of success that he can scarcely repress a feeling of pity not unmixed with contempt for the veterans who have grown gray in the practice of their art, and who have, perhaps, little reward to show for their long and faithful service but honorable scars and a premature old age, and who often lack even that retiring pension granted by their country to soldiers whose ambition and business it is to destroy life and not to save it. The proverb tells us that "the first step is always the most difficult," but the young physician takes that step with braced sinews and a heart swelling with hope. It is the steps that follow which cost, when his disillusion has begun, and when he perceives that the theories which promised to form so sure a foundation for his practice have played him false. "Like little wanton boys that swim on bladders—but far beyond his depth," his "high-blown pride" at length breaks under him, and leaves him "weary and old with service, to the mercy of a rude stream that must forever hide him." Of all the splendid apparatus of science on which he staked his hopes, none does its work any longer, nor produces to good purpose, save only that which is moved by powers he had learned almost to despise, the authority of experience and the genius of common sense.

But, you will object, although the young cannot expect to possess the wisdom, the caution, the balanced judgment of the old, are their faith, hope, and enthusiasm to count for nothing? By no means. Wisdom is the fruit of a prudent man's experience, but faith and its attendant sentiments spring up in the virgin soul of youth, and shame on the hand that would blight or crush them! But it is none the less true that they who have learned life's lesson are bound to save from self-deception those who have it still to learn, and as far as possible warn them of the errors and pitfalls in which so many have seen their hopes perish. Surely the voyage of life will be neither less secure nor less pleasant if made with a chart that marks the places where storms occur, or shoals lie in wait for the unwary, and which shows at the end no El Dorado of the imagination but the homely haven where peace and honor dwell. Of all who hear me now, not one whose life is spared need fail of that attainment. Only two things are essential, to live uprightly and to be wisely industrious. Whoever does these things need not fear the future. If he become successful, eminent, famous, to them he must owe his success. If he remain poor, humble, and obscure, his clear conscience will stand him instead of much riches, and perhaps make his home all the sweeter for its homely virtues. These thoughts remind me that the physician belongs to a much larger family than is sheltered by the domestic roof, and to which he is bound by the strong, yet tender ties created not only by a common training, but by the constant and reciprocal interests of professional life. It is sometimes asked why the medical profession alone should require a code of ethics for the regulation of its conduct? The question is not without the flavor of a sneer, and implies that there must be something peculiarly perverting in the science of medicine, or corrupting in its practice which renders necessary so formal a statement of its moral duties. Let us consider the matter.

The moral government of mankind has never been entrusted to merely abstract propositions. The most ancient of moral codes, the Decalogue, maintains its authority unbroken by thousands of years. Their sum and substance are embodied in the two simple precepts of the founder of Christianity, and yet the former was expounded by Moses and his successors into an elaborate system of law, was adopted into Christianity, and thence by all the civilized nations of the world, until it has interfused the legislation under which we live at the present day, and not the legislation only but the usages of society in all ages. Wherever law reigned men who were similarly employed were drawn together into guilds and societies for the common benefit of their members, and in each statutes were enacted which enforced compliance with them by heavy penalties. Even among trades ethical rules existed, and when the learned professions were gathered into their respective colleges or faculties the privileges and rights of the members were counterbalanced by laws for the regulation of their conduct. The clergy alone were destitute of any specific ethical code, because they were held to be especially under the divine law from which all other codes emanated, and yet every religious community, of whatever denomination, possessed, and still possesses, special rules of conduct by which its members must be governed. The necessity of ethical codes arises from the fact every-

where and always recognized, that either through lack of instruction, or through a defective or perverted moral sense, or through mere heedlessness, men do fail more or less to conform their conduct to justice and equity.

If men were habitually virtuous and just, unselfish and generous, if they could always see themselves as others see them, and judge their own motives and actions as strictly as they judge of other men's, then, indeed, there would be but little need for ethical or religious laws, for "they that are whole need not a physician." But law is nature's medicine for nature's defects and errors. Whoever imagines that he needs it not, that he possesses an inner light that will prevent his feet from straying into the paths of error and enable him to decide justly in every conjuncture of life, is more to be wondered at for his boldness than admired for his modesty, for he lifts himself into a judgment seat where even Solomon did not dare to sit.

I have said that the relations of a physician to his brethren and to society differ widely from those of other professional men, and, indeed, of all other men whatever. The emulation and rivalry of clergymen and lawyers are, for the most part, displayed before the eyes of the world, so that there is no special opportunity for an evil-minded man of either profession to back-bite or malign his brethren. Moreover, he knows that if he offends in this manner, the court may affix a stigma to his name, or the religious body, or the superior, upon whom he depends, may ruin him by an ecclesiastical condemnation. In the medical profession there is no tribunal which is under such imperative obligations to act, or enforce its decisions so rigidly. Hence, one necessity of a code of ethics. But another, already implied, is even more cogent. The physician is the only human being who is habitually admitted behind the scenes of life's stage. He is the depository of secrets to which even a confessor's ear is a stranger—secrets on which station, honor, and life itself may depend; and, even when not so burdened, he is more than anyone else the confidant and friend of those whose diseases he has healed. He is often the guardian of families that put their trust in him. Is it any wonder, therefore, that he should be jealous of the intrusion of a rival, or even of a friend, upon his preserves, and that, the evil of human nature aiding, the rival should endeavor to supplant him, and that thereout coldness, estrangement, animosity, evil speaking, and ill treatment should arise? Or is it surprising that the very confidential relations of a physician to his patient should expose him to the temptation to do wrong, and that he should, therefore, be warned by written laws of the danger he incurs?

These are the grounds out of which the ethical principles of the British and the code of the American medical profession grew, and which inspired the works of French and German writers on the same subject. They are the principles of honor, morality, and whatever is best in modern civilization, and, therefore, should be had in respect by all. It is a sign of decadence in the American social and medical systems that such laws are treated as obsolete or superfluous, and sneered at as fit only for children in leading-strings. Let me, as the parting counsel of one not without experience of life, adjure you to hold fast to this rock of safety, and, far from aiding to abrogate it, to strengthen and perpetuate it by every means in your power.

Impatience of authority and restraint has, perhaps, a deeper source than I have yet indicated. Its most conspicuous and violent outbreak occurred in France a century ago, and for a time covered the country with ruins steeped in blood. In our own day, the rebellion against law, if less sanguinary and destructive, is not less vehement, and is far more extended. Its name is Nihilism, and its creed is the denial of whatever has been known as religion, a hatred of all the virtues that are the fruit of faith, and a contempt of the obligations imposed by law. It tends to rob man of trust in whatever has been loved or respected in religion, in law, in the love and authority of parents, in the affection and obedience of children, in virtue, in duty, in honor, and in the established order of things that links the present to the past and to the future, making it the offspring of the one and the parent of the other.

If it were possible for this egoistic materialism to endure and prevail, the winter of humanity would indeed be near at hand, in which all signs of life, all progress and development, all beauty and nobility would be frozen out of it, and mankind would be reduced to a lower moral level than the beasts of the field. A world without faith! A world without love! As easy were it to conceive of a world without light or heat. In such a chaos what would become of all those institutions that have been established, perfected, and reverenced by advancing civilization? Conceive, for a moment, a community where no song of bell nor inward voice called to worship; where justice had become deaf as well as blind, because every man claimed to be a law unto himself; where there was no balm to soothe, no physician to cure, no right of property, no sacredness of person, where, in a word, mankind had lost whatever has hitherto distinguished humanity. If you can imagine such a herd of human beings — for it will no longer be a society or a community—you may behold in it a picture of the one that will assuredly arise if these nihilistic doctrines, this worship of self, this scorn of faith, this contempt of the past and exaltation of the present should prevail.

Let me plead with you to shun these poisonous principles which tend to the destruction of all that has been held noblest and best by the wise and good of every age; principles which put farther asunder the nations, communities, and individuals whom the physical improvements of the age should bind together and at last fuse into one. Faith is the parent and preserver of all good works. Unbelief, like Saturn, devours its own children. Faith is to man's nature what sunlight is to the world, clothing it with beauty and life; while unbelief is like the moon, in which the sun's rays create neither motion nor color, but fall forever upon its lifeless orb. Without faith, man's ambition is but narrow selfishness, contemptuous of the historic past on which it is compelled to build, and careless of what evil germs it may plant to be developed in the future. The higher a man rises in his humanity, the more clearly does he feel himself to be a link between the past and the future; the more fully recognize that what he has received that also must he transmit, increased, perfected, and consecrated by that spirit of love for humanity without which "good gifts wax poor."

It has again and again been said, of old and in our own day, that the physician's office is a priesthood, a service of the divine for the sake of the human. It does not exist for the discussion of scientific problems, except in so far as they relate to the prevention and cure of disease. Whatever is contrary to this may be science, but it is not medicine, and he who practises medicine in an exclusively scientific spirit very soon divorces his affection from his life's work, and leaves it barren, spiritless, and unsatisfying. No man can become a great physician whose heart is not in his work at least as much as his intellect. It is a work of charity and love, of self-denial and long suffering, and yet, like all work that crushes down the selfishness of the human heart, its rewards are beyond price, and can be understood only by him who receives them. Many of you have heard of the great anatomist Vesalius, and seen the print that illustrates the devout spirit with which he pursued his immortal investigations even under the ban of religious persecution. By such a spirit ought we all to be guided and controlled, never divorcing from science and art the divine sentiment of their brotherhood to one another and to every human being that needs the succor of our skill.

Other subjects there are, besides those I have caused to pass so rapidly before you that I may well fear they will leave but an indistinct impression, subjects hardly less urgent for consideration—but I must hasten to bring this, our last public interview, to a close. Looking back over the score of years which divides the beginning from the end of my professorial career in the University, and comparing the classes of the one period with those of the other, I cannot avoid recognizing the steadily improving culture of the students I have had the pleasure of addressing, and that during the later years of my experience the classes have been much more receptive of knowledge and far better able to appreciate it than their predecessors. In former times, after the examination of certain candidates for the degree, I have felt my spirit sink under the thought that they were to be entrusted with the care of health and life. I did not blame them, I pitied them; but I did blame and utterly condemn the system which introduced such persons into the medical profession. You have lived under a different dispensation; and during the years that it has been established, I have been spared the pain and the shame which were once the heaviest burdens of my office. I have enjoyed the satisfaction of seeing reflected in your faces an intelligent and interested appreciation of what it had become a pleasure to teach. This sympathy with my audience has been the sharpest spur to my endeavors to be worthy both of my subject and of them. I have felt that in emphasizing and reiterating certain views and precepts I was teaching a lesson not to be learned by rote, but that would sink deep and always remain in the retentive minds of my hearers. Never before did I feel so strongly impressed with the dignity as well as the responsibility of the teacher of medicine. And hence it is that, standing now upon the further verge of my professorial career, I can bid it farewell with a cheerful and contented spirit, satisfied that in the future those who may hold this Chair will be still more worthy teachers, and that your successors will be still more accomplished students.

To those who have followed my lectures, I return my heartfelt thanks for their great courtesy and consideration, and, above all, for that interested attention which is the best evidence a teacher can receive that his labor is not in vain. To you, to all who hear me, I offer my most earnest wishes for your success in life, bidding you to love mankind, to love your profession, and, above all, to LOVE TRUTH.

SPASMODIC SWALLOWING, OR RETRACTION OF THE TONGUE.[1]

BY RICHARD HENRY THOMAS, M.D.,
PROFESSOR OF DISEASES OF THE THROAT AND CHEST IN THE WOMAN'S MEDICAL COLLEGE OF BALTIMORE, ETC.

My attention was called to this rare accident in the following way. In the latter part of last month, I was attending a young lady for violent idiosyncratic coryza, which presented all the symptoms of hay asthma. According to the history she gave, she has been subject to these attacks for about three years. They are not brought on by the emanations from grasses or flowers, and they are more frequent during the winter than the summer. The more usual exciting causes are foul odors, dust of flour, and ordinary dust, and she said that the same effect had been produced by almost all the local applications used for the relief of the chronic nasal catarrh from which she also suffered. During this present attack, breathing through the nose was much interfered with; there were considerable dyspnœa, especially on lying down, and a sense of constriction over the upper part of the sternum. The dyspnœa was unlike that of asthma, to which she had an inherited predisposition, in being distinctly inspiratory in character, though the expiration was also somewhat embarrassed. Examination of the chest revealed only mucous râles in the bronchi of medium size.

Although these attacks had only troubled her during the past three years, the chronic catarrh, which so generally is one of the strong predisposing causes of idiosyncratic coryza, commenced in her eleventh year, and was first noticed after prolonged exposure to a severe snow-storm. Since that time also she has had two attacks of diphtheria, one of them especially severe, and affecting the nose. The form of the catarrh was hypertrophic.

She was recovering from her attack with more than usual rapidity and ease, and was expecting to resume her ordinary duties the next day, and I was about to commence the treatment of the chronic trouble, when, about 9 P.M. on the 2d inst., I was hastily summoned to her, the messenger stating that she was choking. Putting what seemed to be needed into my satchel, I started off at once, expecting to find her in one of her ordinary attacks of more than usual severity. When I arrived, it was evident from the surroundings, that her attendants had been very much alarmed, though the more urgent symp-

[1] Read before the Baltimore Medical Association, March 24, 1884.

toms had been relieved. The history of the attack was as follows: Shortly after I had left her, early in the afternoon, she began to notice a sensation of numbness on the left side of the tongue, and a sense of trembling in it. The sensation afterwards extended to the other side of the organ. She took no special account of it, but had some difficulty in pronouncing certain words. This, she said, was not very unusual with her, and she attributed it to the fact that she had always been considered a little tongue-tied. In the evening, however, her friend in reading came across the word "biliary," which, not understanding, she tried to explain to her, but found it impossible to pronounce it. Soon after, she felt a great desire to swallow, and suddenly felt her tongue fly back down her throat, so as to prevent her breathing. The spasm was a tonic one, and lasted about half an hour. As she had heard of the accident of the tongue falling back during chloroform inhalation, and had, from nursing and other means, an intelligent idea of medicine, with great presence of mind she seized her tongue, and drew it forward, and found her breathing at once relieved. The moment her hold relaxed, the tongue was again forcibly drawn back. She found some relief in taking very small sips of black coffee, and noticed that pressure behind the rami of the lower jaw helped to lessen the distress. She remained calm and self-possessed, and showed none of the commonly known hysterical symptoms. Every few minutes, I noticed, there would be a convulsive movement of swallowing, and there was considerable pain. I immediately gave her some whiffs of chloroform, which afforded instant change in her sensations, and relieved the spasmodic movements for a time.

Except when the tongue was drawn back there was no interference with respiration, nor was there any acceleration of the breathing, nor of the pulse, which remained regular and of fair strength.

Thirty grains of bromide of potassium every two or three hours were ordered. I remained with her until about midnight, administering more chloroform when the tendency seemed to be returning, and gave directions that, should there be any symptoms of another attack, half a teaspoonful of chloroform be poured upon a wet sponge at the bottom of a small, wide-mouthed jar, from which she was to inhale the fumes. As there was gastric disturbance, calomel in one-tenth grain doses was ordered.

The next morning I found her very weak. She had had two slight returns, which had been controlled by the chloroform, and had slept but little. I continued the bromide, and left a pair of forceps with her for more ready use in case of a recurrence of spasm. The further treatment consisted in iron and quinine, with nervous sedatives and tonics, and good food. After the next evening no symptom of a return appeared. As the attack was going off, she referred the pain also to the soft palate, and the sensation of numbness she had felt in her tongue went off as it had come on, affecting the left side last. This was the only attack she had ever had, and it was described as entirely unlike the spasmodic affection of the air-passages to which she was accustomed. The history of the case and symptoms also exclude any diagnosis, but the one I have given—that it was a case of so-called swallowing of the tongue. It will be noticed that the word she was unable to speak at the commencement of the attack is rich in linguals, "l" and "r" being the emphatic letters. For a fortnight after this there was great debility, which gradually yielded to treatment.

I have entered thus minutely into the history of the case, because of its extreme rarity. Dr. Ingalls, of Chicago, reported a case to the American Laryngological Society in 1880.[1] He said that he had heard of another instance from non-professional sources, but knew of no other case of the kind. The other members of the Society, being thus challenged, reported no similar case. Dr. J. Solis Cohen[2] merely remarked that the name "Swallowing of the Tongue," was an incorrect one, and that he had had a patient who complained of the tongue flapping up against the roof of the mouth, who was cured by strong brandy. It is fair, therefore, to assume that none of the distinguished gentlemen then present had met with a similar case.

Dr. Ingalls's patient was an extremely hysterical person. Her attack had been preceded by hysterical convulsions. She was improving when, after eating some soup, there was an eructation of gas followed by suffocation. The doctor was able clearly to establish the diagnosis, as I have been, and, finally, during the last attack the impending suffocation was prevented by pulling the tongue forward with forceps. General treatment was resorted to. After looking through a large amount of literature on the subject, as well as many of the current periodicals, I have not met with any similar case on record as far as concerns the adult.[3]

In infants and young children the case is different. In them the tongue is a much more dangerous organ. According to Hennig,[4] who enters pretty thoroughly into the subject, especially the more recent literature, Petit, in 1742, was the first to describe the accident. His first case was fatal; but in his subsequent experience he was able to prevent death by mechanical means, and devised a

[2] Archiv. of Laryng., 1881, p. 181. Dr. Edwin Morris, F.R.C.S., (British Medical Journal, August 31, 1872, p. 242) reports a case of dislocation of lower jaw, during sleep, through sucking of the tongue in a young lady. Spasm of the tongue, affecting the protrusors, is more frequent. See THE MEDICAL NEWS (Phila.), July 7, 1883, p. 8. Medical Record (N. Y.), December 8, 1883, p. 625. Rhein, Westphal Jahrb. f. Med. and Chir., Ham., 1826, xi. St. 2, p. 34. An article, Ueber Idiopathischen Zungen-krampf, O. Berger, Neurol. Centralb., Leipzig, 1882, i. 49–52, was mentioned in the Card Catalogue of the Library of the Surgeon-General's Office, Washington, but was out of the Library.

[3] C. H. Breidenstein, Krank. der Zunge (Neuest. Samml. der Auserlesenste und Neueste Abhandlungen f. Wundärzte, 5 St., pp. 258–286, Leipzig, 1792) mentions the accident, but records no case. In the discussion which followed the reading of this paper, Prof. Ashby spoke of having seen a report of a case somewhat like this, by Dr. Wood, editor of the North Carolina Medical Journal, about eighteen months since.

[4] Ueber Sogenanntes Verschlucken der Zunge, von C. Hennig, Leipzig, Jahrb. f. Kinderheilk., Leipzig, 1877, p. 299. An abstract of this is given in the American Journal of Obstetrics, January, 1878, p. 208.

bandage for holding the organ in place. I found this bandage described by Herr Dr. Stammer[1] as very clumsy. Petit refers his cases to the too deep cutting of the frenum in tongue-tie, or to congenital deficiency of the frenum. This cause is also given by Dr. Veh, of Moscow, as one not infrequently leading to the accident in Russia, as also by Dr. Stammer in his case, recorded by Dr. A. Dröste.[1]

Another frequent cause is whooping-cough. Hennig, in explaining the *modus operandi* in these cases, states that during the violent expirations the under surface of the tongue in infants who have cut the two lower incisors is wounded by the teeth on both sides of the frenum, giving rise to ulcerations. Afterwards, during a forcible inspiration, the tongue is carried back by suction, and the pain from the ulcerations adding its influence, the tip of the tongue becomes curved upwards and backwards, and may be caught between the palate and the base of the tongue, in which case the ensuing expiration cannot dislodge it, and sudden death is the result. This was the case in two infants in neither of whom had there been any cutting of the frenum. Another instance is given by Dr. Seydeler[2] of a fourteen-day old infant who, on being given for the first time a few drops of medicine from a spoon, not knowing what to do under the unusual circumstances, swallowed its tongue, and was only saved from impending death by the doctor drawing the tongue forward. In this case the tip was not turned upward.

The tongue gives trouble also in the newly born during attacks of coryza.[3] The infant, in sleep, breathes through the nose almost exclusively, while the tongue lies close against the soft palate. In coryza it cannot do this, and, especially if it be lying on its back, the tongue is apt to remain in its usual position, and to lie even more firmly fixed against the soft palate. Hence arise dangerous suffocative attacks. That this is the cause of them is shown by the fact that changing the position of the child diminishes the frequency of the attacks, as well as by the relief afforded by pulling forward the tongue. It is not necessary to refer to similar accidents in chloroform inhalations, or to the danger of it after operations on the lower jaw.

It will be seen that in their causation and history there is very little in common between the so-called swallowing of the tongue in children and in the case of the lady I have just reported, or the one reported by Prof. Ingalls. In children, with, perhaps, the exception of the infant reported by Dr. Seydeler, the cause is simply mechanical, the tongue either falls back, as it does in chloroform narcosis and after operations on the lower jaw, or it is drawn back by suction. In the adult, the affection is clearly spasmodic, and has nothing to do with the position of the patient. Prof. Ingalls rightly considered the spasm in his case to be due to hysteria, and this may be the true explanation of my case also, although there was no previous history of hysteria, or any other hysterical symptom during the attack. It is, perhaps, more probable that it was due to the same reflex excitation in the nose that was almost certainly the cause of the asthmatic attacks. Another possible exciting cause was the gastric irritation which was present in her case, as well as in that reported by Dr. Ingalls. The prolonged debility which followed the attack might point to a more serious origin than reflex action (for days the mere walking across the room would weary her), but a careful study of the symptoms and history of the case seems to exclude a central origin, and after her previous attacks of idiosyncratic coryza, her strength has returned but slowly. In the present state of our knowledge, the cause must remain in some doubt. The muscles involved were the hyoglossus and styloglossus especially, though apparently most of the muscles concerned in the first act of deglutition were affected, as the ease gained by pressure behind the rami of the jaw, and the pain referred to the soft palate, after the attack passed off, further indicate.

As the two classes of cases are so distinct, they should be distinguished by different names, and as "Swallowing the Tongue" has been applied so long to the accident when induced by mechanical causes, I would suggest for the affection I have described the name of "Spasmodic Retraction of the Tongue."

As these attacks are of immediate danger to the patient, it is of the utmost importance to fulfil the first indication for treatment, which is to seize the tongue and draw it forcibly forward, and to maintain it in that position. The patient or the attendants should be furnished with forceps and instructed how to use them. After the first attack, the second does not occur without premonitory symptoms, readily recognizable by the patient, who has a most vivid and painful recollection of the preceding seizure. As soon as these symptoms appear—involuntary efforts at swallowing being among the most prominent—inhalations of chloroform or other anæsthetic should be used. With careful directions, it is quite safe to let the attendants administer the chloroform without the physician. The method of dropping a moist sponge, on which half a teaspoonful of chloroform has been poured, into a wide-mouthed jar is a good and safe one, for it is not necessary to inhale much, and the dose may be repeated. This will almost certainly ward off the attack. After the tongue has been drawn out the chloroform may be used while the spasm is still on. Other methods may be employed, such as dashing cold water on the face, etc.

As the affection is accompanied and followed by great nervous prostration, nervous sedatives must soon be followed by nervous stimulants, as asafœtida and valerian. Ferruginous tonics and general supporting treatment are indicated.

COMPLETE ABSENCE OF VAGINA, WITH ATRESIA OF THE UTERUS.

By J. C. REEVE, M.D.,
of Dayton, Ohio.

Cases of the class to which this one belongs deserve record from their extreme rarity, even were there no unsettled points as to the best methods of conducting measures for their relief.

I was called to see Miss L., just past fourteen years of age. Learned from her parents that she was born at or about the end of the eighth month of gestation, and was very small at birth, weighing not more than four pounds. She had generally enjoyed good health until a little over a year ago, when her change of form and appearance seemed to indicate that she had arrived at puberty. About that time she began to suffer attacks of pain, which recurred periodically at about monthly intervals, and which had increased in severity, and gradually lost their periodical character, until now they were extreme in degree, even sometimes causing her to roll on the floor, and came on at uncertain intervals of a few days or a week at most, and lasted several days at a time.

There was one peculiarity of these attacks deserving mention—the position she assumed when suffering. She was accustomed to stand on her left leg, the right one flexed, with the ankle resting just above the left knee. Standing thus, and leaning her hands on some article of furniture, she passed many hours together; on one occasion, fourteen hours, as her parents aver. For a few minutes at a time now and then she knelt, and latterly had been standing sometimes on the right leg, but with the left in the same relative position as above described. This seems to have been one of those instinctive positions in which patients find that they get mitigation of their sufferings.

For four months she had been under the care of a physician, an eclectic, who had been administering medicines to "bring on her turns." She also had been seen once by a regular physician, but no examination had been made or proposed until she came under the care of the gentleman with whom I saw her—Dr. W. P. Weaver, of Miamisburg, Ohio.

Examination showed, in the hypogastric region, a round, smooth, elastic tumor, which extended upwards to the left, and nearly as high as the umbilicus. No opening could be discovered between the labia. By the rectum a round, smooth, elastic body could be felt projecting downwards into the pelvis and its identity with the tumor felt through the abdominal walls was verified. No trace of a vagina could be discovered, but all examination in this direction was very unsatisfactory, from her exceedingly nervous condition, the result of the pain she had suffered.

The nature of the case having been explained, and the necessity of an operation stated, I returned in about a week to perform it. A hypodermic injection of morphia and atropia was administered, and about twenty minutes afterwards she was placed under the influence of the mixed vapors [A. 1, C. 2, E. 3]. She was put in the lithotomy position, and a careful examination was then made, but no vaginal canal could be discovered; there was no vulvar opening—all was solid below the opening of the urethra—and by the rectum, no trace of a vagina, no fibrous cord or thickening to represent one could be felt. A sound having been placed in the urethra, and held by Dr. Weaver, one finger of the left hand was introduced into the rectum, and a transverse incision made with scissors between the labia, and nicked above and below. I then bored with right forefinger upwards towards the uterus, and thus very easily channelled a passage up to the uterus. With a rectum-speculum this passage was then dilated, and afterwards, by the expansion of the blades of a Nott's trivalve speculum. In the next step of the operation vision was of no assistance, on account of oozing of blood, but neither by sight nor touch could any indication be found of a particular point at which to open the uterus. There was not even a dimple to mark the position of the os, nor was there any projecting portion like a cervix; the tumor was nearly globular in shape. I penetrated it with the largest sized trocar of an aspirator until resistance was felt to cease, and withdrew about an ounce of chocolate-colored fluid. The instrument then choked, the fluid being too thick to be withdrawn in this way. I then carefully introduced a bistoury in the same manner and turned it on its edge as it was withdrawn. Keeping my finger in contact with the opening, a uterine dilator was passed in and expanded until the finger passed freely into the uterine cavity. From four to six ounces of the same tenacious fluid escaped. The channel made was syringed out with a solution of carbolic acid, a large hollow tupelo tent placed in the uterus and supported by tampons of marine lint wet in the solution, thus completely filling the artificial canal.

Her recovery from the operation was uninterrupted. The syringe was used daily by the gentleman in charge of the case, and the lint changed. On the third day a large quantity, estimated at a quart, of the accumulated fluid was expelled. I saw her one week after the operation, when I could pass my finger readily up to the uterus, and she was then provided with a vaginal plug, and her mother instructed in its application. Two weeks afterwards, she menstruated naturally and without pain.

Whether the operation should be completed at a single sitting, and whether the uterus should be washed out antiseptically, are the open questions in regard to such cases as this. In regard to the first, it seems to me that there can be no doubt, even when the patient is not, as mine was, at a distance from the operator. The demand, the necessity, for relief are urgent, and it does not seem possible that greater safety will be secured by making successive steps to it, to say nothing of the mental influences on a nervous and timid girl. In regard to the second point, I presume there are few, in these days, who would not wash out the uterus thoroughly. I would not advance against it the plea that danger might arise from passage of the fluid through the Fallopian tubes into the peritoneal cavity. Any fear of such a result, where the imprisoned fluid

has been subjected to pressure, as in this case, for months from uterine contractions, can only be absurd. But safety would seem to be best secured here, as after labor, by efficient contraction of the uterus and obliteration of its cavity, and that where circumstances will allow it, measures to bring about these conditions are the ones for the operator to adopt. However, this is intended to be rather a record of facts, than a discussion of opinions, and the case is reported for whatever benefit may result from it.

THE PATHOLOGY, ETIOLOGY, PROPHYLAXIS, AND TREATMENT OF PUERPERAL FEVER, FROM THE VIENNA STANDPOINT.

BY W. W. JAGGARD, M.D.,
OF CHICAGO, ILL.

THE doctrines of the Vienna School of Obstetrics, upon the subject of puerperal fever, are clear and distinct, from a theoretical standpoint, while purely speculative tendencies have been checked by careful clinical observation and experience, and exact pathologico-anatomical investigation. The colossal material, facilities for observation and experiment, before, during, and after parturition, and the obligatory character of *post-mortem* examinations, afford a field for investigation of unparalleled scope. The protocols, containing minute, accurate records of each individual case, accumulating through long years of patient research, furnish corrective and corroborating statistical evidence.

Add to this the consideration of the names of the illustrious men who have engaged in the study of puerperal fever—Rokitansky, Oppolzer, Skoda, Billroth, Carl and Gustav Braun, Spaeth, Kundrat—and the teachings of this justly famous school are invested with a peculiar dignity, power, and authority.

It is the object of this paper to sketch briefly the salient points in the pathology, etiology, prophylaxis, and treatment of puerperal fever as taught and practised at the present time in Vienna.

I. PATHOLOGY: Puerperal fever is an infection fever, in which inflammations of the genital mucous membranes and serous membranes—most frequently the peritoneum, at times, also, the pleura or pericardium—constitute the most prominent anatomical changes, and possess something of a typical character in so far as a continued fever, of great intensity, with temperature elevations up to and above 41° C., usually coexists (Braun).

The site of the puerperal wound comprehends the entire extent of the mucous membrane lining the uterine cavity, and contributing to the formation of the decidua. The deeper strata of the mucous membrane, and, particularly, Friedländer's glandular layer, are laid bare at an early period in labor, when the fecundated ovum is propelled into the cervix. A broad, shallow surface, extending from the internal os to the fundus, is thus deprived of its epithelial covering, rendered accessible to the air and exploring finger, and infection may occur before any influence has been exerted by the trauma of labor. *It is possible, therefore, that puerperal fever may occur during the last weeks of pregnancy and during the first stage of labor.* That it does occur during these periods is a well-known clinical fact.[1]

When this puerperal wound is infected, the danger results from the qualitative and quantitative development of the blood and lymph vessels, and the neighboring peritoneum. Puerperal infection has its starting-point in a local lesion, which may be situated in or about the vulva, vagina, mucous membrane of the cervix, or the denuded intrauterine surface. Abrasion of the surface, in any one of these localities, is followed by an inflammatory infiltration, which results in the casting off of the superficial layers of the *mucosa*, in the form of a grayish-white or yellow membrane, and in the production of the so-called "puerperal" ulcers. These "puerperal" ulcers, small in extent, and shallow in depth, increase in both directions with astonishing rapidity, until they may occupy the entire vulvar, vaginal, cervical, or intrauterine expanse. About the vulva and in the vagina, stratum after stratum yields to the destructive process, until the perivulvar and perivaginal connective tissue is invaded; the cervix may alone be attacked but the intrauterine surface is more usually involved, the decidua thrown off, as grayish-yellow membranous shreds or fragile masses, and the *muscularis* laid bare.

Birch-Hirschfeld applies to this process the terms puerperal diphtheria, diphtheritic endocolpitis, and diphtheritic endometritis. He implies by this terminology a pseudomembranous necrosis of the *mucosa*, resulting from inflammatory infiltration and molecular destruction of its elements, essentially the same condition as diphtheria of wounds. He denies emphatically any relationship with diphtheritic angina. General unanimity of opinion upon these primary considerations prevails at the present day. The case is very different with the further course of the disease.

Buhl, in 1861, described three chief forms of puerperal fever, and this classification has been accepted in Vienna, in preference to the complicated and forced division of Spiegelberg.

Buhl's three forms of puerperal fever are:

1. Puerperal peritonitis, without pyæmia (endometritis, salpingitis).

2. Puerperal pyæmia, without peritonitis (metrophlebitis).

3. Puerperal pyæmia, with peritonitis (pyæmia with lymphangitis, parametritis).

1. *Puerperal peritonitis, without pyæmia,* includes those cases in which the inflammation extends from the endometrium through the tubes to the peritoneum. The tubes are enlarged, the *mucosa* swollen, injected, and pouts through the fimbriated extremeties; the lumina, increased in size, are filled with thick pus; the uterine *mucosa* presents the characteristic appearances of endometritis; the resulting peritonitis may be circumscribed or general. The external surface of the uterus is of a lively, vermilion color, and upon section fine red

[1] Carl Braun's Gynækologie, p. 853.

lines, due to the extravasation of blood between the muscular fibres, constituting apoplexy of the uterus, are noted.

This form is most frequent when there is no epidemic influence.

2. *Puerperal pyæmia, with peritonitis*, is developed when the infection gains access to the bloodvessels. Infection has its starting-point, by preference, from the placental site, where the endometritis produces ichorous destruction of the thrombi formed in the uterine sinuses. Thrombosis of the veins of the uterine walls, pampiniform and spermatic plexuses result, and the process of embolism is established. Metastatic abscesses are formed in the lungs, spleen, kidneys, and brain. Metastatic inflammation of the joints, serous cavities, superficial and intermuscular fasciæ, constituting phlegmasiæ—skin, constituting erysipelas — may occur. Ulcerative endocarditis is usually present. The spleen becomes enormously enlarged. The blood is fluid and thin, and putrefaction makes rapid progress after death. It is needless to add that such cases terminate fatally at an early period of the disease, with symptoms of profound toxæmia.

This form of puerperal fever is familiarly known as septicæmia.

3. *Puerperal pyæmia with peritonitis* arises when the poison is received into the lymphatics and connective tissue of the parametrium.

As the result of an antecedent puerperal endometritis, the intrauterine surface is covered by a layer of stinking, brownish-colored, decomposing decidua or pus. Ulcers and fissures, covered with molecular *débris*, are found in the cervix. Very rarely, the uterine walls, throughout their entire thickness, in smaller or larger areas, are involved in a gangrenous process; and a condition termed by Boër *Putrescentia uteri* results. The inflammatory process is usually propagated through the intramuscular connective tissue, and follows the lymphatic paths. The lymphatic vessels are seen, especially in the neighborhood of the tubal insertions and cervix, according to the direction of the section, as yellow, dilated, varicose vessels, or as round lumina, out of which pus flows copiously. The vicinity of the lymph vessels is infiltrated with pus; abscesses occur between bundles of muscular fibres, and are sometimes so near the *serosa* that they appear like vesicles.

From the uterine walls the inflammatory process reaches the pelvic connective tissue. The lymphatics, filled with pus, can be seen running through the broad ligaments to the *hili* of the ovaries, causing, at times, purulent infiltration and abscess formation in these organs. The pelvic connective tissue, at the same time with the lymphangitis, is involved in a proportionate parametritis, resulting in purulent collections and discolored serous effusions, shading off into lighter degrees of œdema. The inflammation may involve the connective tissue of the abdominal walls and lower extremities, where it frequently acquires an intense, phlegmonous character. The peritoneum is reached, through the subperitoneal connective tissue, usually upon both lateral surfaces of the uterus. The fimbriated extremities of the tubes become the seat of the inflammatory process. General peritonitis, with serous, fibrinous, purulent, or ichorous exudations, is rapidly developed, and may be extended through the diaphragm into the pleural cavities. *Meteorismus*, as the result of the serous infiltration of the *muscularis*, is marked. Parenchymatous degeneration of the liver, kidneys, and spleen, ulcerative endocarditis, usually accompany this form of the disease.

Microscopic examination of the uterine walls reveals diffuse infiltration of the intramuscular connective tissue by pus corpuscles and molecular *débris*. The muscular fibres are swollen, and the nuclei are dark colored. This condition of the intramuscular connective tissue and of the muscular fibres explains the extreme fragility and brittleness of the uterine walls in women suffering from puerperal fever.

The infection may arise in vulvar or vaginal "puerperal" ulcers, but the mode of origin sketched in the foregoing sentences represents the more usual condition.

The children of women affected with puerperal fever succumb frequently to the poison received through the maternal blood. The infection may occur during pregnancy, and this fact demonstrates, beyond possibility of doubt, the transference of the poison by the maternal fluids. Ecchymoses and inflammations of the serous cavities, phlebitis and umbilical arteritis are usually observed. The umbilicus is frequently the place of invasion. (Braun.)

This form of puerperal fever is of most frequent occurrence, and is referred by Virchow to the class of phlegmonous inflammations and pseudo-erysipelas.

These different forms of puerperal fever may occur simultaneously in the same epidemic. It is not necessary, however, to invoke a qualitative difference in the infection, or "*materia peccans*." The variance in symptomatology and pathologico-anatomical conditions is fully explained by the different paths selected by the poison. (Birch-Hirschfeld.)

The results of all pathologico-anatomical investigation of puerperal fever point to the reception of a disease which has its origin in the genital canal, and demonstrate the occurrence of relationships in puerperal fever of exactly the same nature as in the pyæmic infection of wounds. (Braun.)

II. Etiology: The general proposition that puerperal fever is infectious, that is, is transferable from a diseased to a healthy woman, may be regarded as demonstrated.

Cruveilhier (1831), Semmelweis (1847), Simpson (1850), Rokitansky, Skoda, Oppolzer, Winckel (1869), Spiegelberg (1870), Schroeder (1874), Landau (1874), Lee (1875), Kehrer (1875), and numerous other observers have abundantly established this proposition. It is a fact of positive knowledge. The nature of the infection, the "*materia peccans*," is a controversial subject.

Before entering upon the discussion of this subject, it is well to repeat the statement, that the Vienna School of Obstetrics recognizes strict analogy between puerperal fever and septico-pyæmic processes in general.

Three theories as to the nature of the infection,

materia peccans, of puerperal fever, are entitled to consideration. They are:

A. The bacterial theory.

B. Billroth's phlogistic zymoid and putrid poison theory.

C. The miasmatic theory.

A. The Bacterial Theory.—Mayrhofer (1865) demonstrated the presence of numerous vibriones in active motion in the secretions from the genital canal of patients suffering from puerperal fever, in the Vienna obstetrical clinics. Virchow and Buhl described, about the same time, fine molecular masses in similar secretions. Later, Waldeyer corroborated the researches of Mayrhofer, and demonstrated the presence of vibriones in the covering of "puerperal ulcers," lumina of the uterine lymphatics, infiltrations into the connective tissues of the parametrium, exudations into serous cavities, and asserted that the molecular masses of Virchow and Buhl were composed of micro-organisms. Heiberg followed, and supported Mayrhofer so far as concerned the actual presence of vibriones, but expressed himself reservedly as to their causative relation. Orth emphasized the discoveries of his predecessors, but claimed that the sphero- and not the rod-bacteria were causative. Birch-Hirschfeld recognizes the position of the latter observer. Klebs, Rindfleisch, Cohn, Recklinghausen, and Hueter may be added to the number of distinguished pathologists who believe bacteria to be the essential cause in all septico-pyæmic processes.

B. Billroth's Theory of Phlogistic Zymoid and Putrid Poison.—Billroth (1874) opposed the bacterial theory by his thorough and exact researches into the nature of accidental wound fever. Billroth's theory receives its best exposition in his own words:

"The etiological relationship of bacteria to septic diseases and putrescence of the blood is by no means to be regarded as demonstrated.

"Out of the acutely inflamed connective tissue, is added to the pus a ferment similar to zymoid material (Phlogistic Zymoid), which induces its decomposition. By this means the pus, before an uncongenial soil for the development of micrococci, now becomes a peculiarly favorable menstruum for their multiplication—it is unsettled whether this zymoid, as such, is assimilated by the micrococci, or whether it induces a decomposition in the pus upon the products of which the micrococci live. Zymoid and micrococci can then no longer be separated from the pus, without the annihilation of its zymoid action.

"The further existence and action of the zymoid are not conditioned upon the vegetation of the micrococci; the decomposition continues even if the micrococci perish.

"By Phlogistic Zymoid is understood a substance which, produced by inflammation, is capable again of producing inflammation.

"There is no doubt that coccobacteria are not necessary to produce pernicious forms of acute inflammations, and they are not necessary in the diffusion of these inflammations throughout the body; that coccobacterial vegetations are not, as such, ferment producers; that these organisms must bring within themselves, or upon themselves, the specifically active substance; that they are not ferment bearers under all circumstances, but are only then ferment bearers when they come out of a fluid in which the specific ferment already existed.

"Every acute inflammation has a stage in which it produces secretions capable of infection, and the infective capability of diphtheritic secretions possesses no peculiarity, except that this stage lasts a peculiarly long period of time.

"Recently Panum has obtained from macerating, decomposing meat a substance, soluble in water, and containing no albumen—so-called extract putrid poison; in addition to this, he found a second substance of exquisitely narcotic action. Bergmann obtained from decomposing beer-yeast, a crystallizing body, which he calls sepsin. Finally, Zuelzer and Sonnenschein have discovered a substance resembling an alkaloid, of septic action."

The phlogistic zymoid and putrid poison are closely related, and ultimately identical, since the chemical processes within the parenchyma of acutely inflamed tissue and decomposing tissue are analogous.

Rokitansky, Jr., (1874) found bacteria in the lochial discharges of healthy puerperal women, and Haussmann discovered micrococci in eleven per cent. of pregnant and two per cent. of non-pregnant women. Septic infection occurred in none of the women. Wolf and Landau have expressed themselves in opposition to the bacterial theory. Panum and Küssner have demonstrated that micrococci are not the direct bearers of infection. A putrescent fluid, after eleven hours' boiling and destruction of all micrococci, retained its infectious action. The researches of Billroth, Tiegel, and Bechamps, supported by those of Ranke, Demarquay, and Hueter, go far to show that bacteria are normal constituents of the human organism. Finally, no unanimity of opinion exists among the exponents of the bacterial theory; no two observers of prominence agree in all particulars. In the words of Carl Braun:

"The significance of bacteria in the etiology of surgical and puerperal fever seems to be a subordinate one; they seem to have no influence upon the origin, and, perhaps, even no important influence upon the course of surgical fever. The putrid poison kills and produces fever, with or without bacteria."

C. The Miasmatic Theory—By miasm is understood a fungacious contagium; not a gaseous body, but dried spores of vegetable organisms, which, being brought in direct contact with wounds, cause infection. This theory has no tangible basis; it has not been demonstrated that these dried spores are in the condition to preserve their viability. Vegetable organisms are destroyed by high temperatures, while boiling for hours has no effect upon sepsin. The theory, therefore, is totally inadequate to the explanation of the phenomena.

The causes of puerperal fever are:

a. Lacerated and contused wounds, gangrene of the genitals, as the result of difficult labors.

b. Decomposition of portions of the placenta or membranes retained within the uterine cavity.

c. Increase of a primary endometritis, vaginitis, or vulvitis to a parenchymatous inflammation, during the puerperium. The catarrhal secretions flow over the injured mucous membranes, act as irritants, and produce ulcers, which may give

origin to phlegmonous inflammations. The term autoinfection has been bestowed upon this condition. Virchow, Winckel, and Braun are of the opinion that an infection of the injured mucous membranes is unnecessary. The increase of the catarrhal inflammation, by means of chemical and mechanical irritants, to a phlegmonous form is amply sufficient to explain the phenomena.

d. Infection of injured portions of the genitals with secretions from ichorous wounds, or cadaveric substances. Infection may be conveyed by the air penetrating to the parts, or by contact with the exploring finger or instrument.

Occurrence: Individual cases of puerperal fever occur in hospitals and private dwellings, among the rich and poor, in people of the most diversified constitutions, and at all periods of life. *Individual cases and epidemics of puerperal fever occur quite as frequently in private practice as in well-conducted hospitals.* Winckel demonstrated the truth of this proposition, so far as pertains to the kingdom of Saxony. Upon investigation of the records of fourteen hundred and eighty-six midwives, he found that more than seven per cent. of all midwives of the land, in the year 1874, reported a mortality of three per cent. of their puerperal patients from puerperal fever.

(*To be concluded.*)

MEDICAL PROGRESS.

The Physiological Action of Bromoform.—Dr. Caj. Frieh. von Horoch, of Vienna, at the close of a paper on this subject, draws the following conclusions:

1. The respiration shows no noteworthy variations.

2. The motor centres of the heart do not suffer under the narcosis, and the pulse remains strong and normally frequent.

3. The peripheral ends of the vagi retain their irritability.

4. The blood-pressure, lowered by the narcosis, stands, in dogs, between fifty-seven and thirty-six millimetres. If in the course of an experiment narcosis is stopped, the blood-pressure becomes normal, but falls again when the animal is again narcotized. The centres which control innervation of the bloodvessels do not seem to be so sensitive to electrical stimuli as in the normal state.

5. The reflex irritability was always entirely lost; irritation of the sciatic nerves with the strongest currents had no influence on the blood-pressure.

6. Direct irritation of the vaso-motors (splanchnics) gave no results in deep narcosis, and relatively slight results in slight narcosis.

7. The irritability of the motor centres of the cerebral cortex was completely lost in deep narcosis; in this respect bromoform seems to be similar to other anæsthetics.

8. The temperature gradually sinks in experiments on animals—in dogs, as much as 5° F.—*Medic. Jahrb.*, 1883, Hft. iii., iv.

Œsophagotomy.—Prof. Edward Lawrie, of the Lahore Medical School, reports the case of a woman, æt. 35 years, who was admitted into Mayo Hospital, on December 14, 1883, with a large gall-nut impacted in the gullet. She had been suffering previously from an affection of the eye, and was told by a friend that if she held a gall-nut in her mouth for two hours she would be cured. While giving this plan of treatment a trial, the nut slipped down her throat and lodged in the cervical portion of the œsophagus. During the twenty-four hours following her admission every attempt to dislodge it failed. On the 15th, the patient was very low and distressed, and it was decided after consultation with his colleagues to perform œsophagotomy. The operation was carried out in the usual way, by dissection through the loose cellular tissue between the carotid vessels and the trachea, till the foreign body was felt through the walls of the œsophagus, which was opened by a longitudinal incision, and the nut removed. The woman was fed through a tube for five days, swallowing was perfectly restored in twelve days, and she was discharged cured in three weeks.—*Lancet*, March 8, 1884.

Vesical Calculus Having a Sequestrum of the Pubic Bone for a Nucleus.—Dr. E. Vincent, of Lyons, reports the case of a man, æt. 35 years, who had suppurating sores on all his limbs from justa-epiphyseal osteitis; some of the joints were ankylosed. He had a vesico-femoral fistula, and was greatly troubled with urinary difficulties. All the urine did not pass through the fistula, but the greater part escaped through the juxta-trochanteric fistula. On introducing a sound into the bladder, it stopped at a rough surface in the prostatic region; this, on further examination, was found to be the denuded pubic bone. When the instrument was passed into the bladder, a very large calculus was recognized. The diagnosis was vesical calculus, due to a fragment of the pubic bone, which had fallen into the bladder. The process seemed to have been as follows: there had been an osteitis of the left pubic bone, which terminated by necrosis; an abscess formed, which opened simultaneously into the bladder and through the thigh. When the sequestrum separated it fell into the bladder.

The lateral operation was performed with the galvano-cautery, the calculus removed, and the diagnosis confirmed. The patient recovered.

Vincent also reports a case in which he removed a thermometer from the bladder.—*Ann. des Mal. Génito-Urin.*, March 1, 1884.

Extirpation of the Larynx in an Old Man.—Dr. H. Leisrink reports the case of a man, æt. 72 years, whose parents had died at the age of ninety-five years. The patient had never been sick until two years ago, when he noticed a slight hoarseness. In about a year complete aphonia came on. Afterwards there was impossibility of swallowing anything fluid, and then four days before he was seen attacks of dyspnœa commenced. This was so distressing that he applied for relief. The heart, lungs, and kidneys were found to be sound. Carcinoma of the larynx was diagnosticated, and tracheotomy was performed preliminary to excision of the larynx. Five days afterwards the larynx was removed by Gussenbauer's method. The epiglottis was left, as it was not involved. The mucous membrane of the pharynx was adherent to the posterior surface of the larynx. The Michael tampon-canula, which had been placed in the trachea, answered excellently. The wound

was dressed with sublimate gauze and granulated well. The temperature did not rise above the normal. For several days food was administered through the œsophageal tube, and then through a No. 18 elastic catheter. Up to the fifth day only fluid food was administered. The patient left his bed on the fifth day after the operation, and three months afterward was completely well, but he died in the fifth month of croupous pneumonia.

Although the age of the patient contraindicated an extensive operation, it was thought that the extension of the carcinomatous process to the neighboring glands would soon cause so large a growth that nutrition would be impossible.—*Berl. klin. Wochens.*, February 4, 1884.

SPHACELUS OF THE BLADDER IN DIABETES.—M. TRONCHET, of Bordeaux, reports (*Journ. de Méd. de Bordeaux*, No. 23, 1883) the case of a man æt. 75 years, who, for some time, had had attacks of painful urination and intermittent nocturnal incontinence; the urine was abundant, clear, and without albumen, but contained sugar in large quantity. Being taken with an attack of complete retention, he was catheterized several times with difficulty, on account of stricture; a catheter was then left in place. The patient died in six days, after a progressive diminution of urine, which had become muco-purulent.

At the autopsy it was found that, beside the stricture and hypertrophy of the prostate, the bladder was in a gangrenous condition. It was very prominent above the pubis, presenting, exteriorly, a deep-violet color. Its tissue was extremely friable, and its internal surface covered with a pultaceous mass, the whole somewhat resembling pulmonary gangrene.—*Ann. des Mal. Genito-Urin.*, March, 1884.

NEPHROTOMY.—This operation was performed on February 27, at the Western Infirmary, Glasgow, by DR. PATERSON. The patient was a young woman, æt. 28 years, who had suffered for some years from symptoms of renal calculus. On cutting down to the left kidney some ounces of pus were evacuated, and a stone, weighing one drachm, was removed from the interior of the organ. At last accounts the result of the operation was all that could be desired.—*British Med. Journal*, March 18, 1884.

EXTIRPATION OF AN INTRAUTERINE MYOMA BY MEANS OF THE GALVANOCAUSTIC LOOP.—DR. E. F. FABBRI, of the University of Modena, reports the case of a woman, about thirty-four years old, upon whom he operated. Various means having been used to control the loss of blood and the pains, a thorough physical examination having shown that the growth, which was very large, could be extirpated, though only with considerable difficulty, it was determined to operate. The chief difficulties in the way of operation were the size of the tumor and the fact that the vagina was small, the woman having had no child.

It was not thought best to operate just after menstruation, as the tumor was larger at this time. Fabbri determined, therefore, to operate between the periods of menstruation. In order to obtain dilatation of the external orifice, he provoked uterine contractions by the aid of an elastic vaginal tampon, such as is used in premature artificial delivery. After having dilated the os and drawn the tumor down, the galvanocautery was introduced, the loop being double the long diameter of the tumor. The loop was pushed up to the base of the tumor by means of what Fabbri calls a forked spatula. After considerable difficulty the loop was adjusted and the rheophores were turned on. The loop was drawn slowly, so as to thoroughly cauterize the surfaces. In four minutes the tumor was removed from its attachment, and, after considerable difficulty, from the uterus. The patient recovered easily. The tumor was about the size of a duck egg, and covered with very adherent mucous membrane, except over the anterior two-thirds of its upper extremity, where there was a zone of fibro-muscular tissue.

Fabbri advises the following for exploring the uterus when it contains a large tumor: He does not think well of the Sims's sound, as it is too flexible, and is easily bent by an obstruction, so that the operator is deceived. Instead of this he uses a sound of white metal, the uterine extremity of which has the shape of a finger, but is more flat, has a diameter of two-fifths of an inch, and is slightly olivary. Its shaft is slightly flattened and curved on the flat, but is easily placed in any desired curve. At the close of his paper he draws the following conclusions:

1. Intrauterine myomata of intermittent appearance are probably always free throughout their whole length, and attached near the fundus uteri.

2. In order to explore the uterus which contains a tumor, one should use a sound the extremity of which is somewhat spoon-shaped.

3. For extirpating intermittent myomata, if one operates between the menstrual periods, the os should be dilated, and uterine contractions brought on by means of the elastic tampon, and, if necessary, by introducing an elastic bougie into the uterus.

4. The galvanocautery is preferable to all other methods for removing these growths.

5. Simple carbolic injections are not sufficient for antisepsis; carbolated compresses should be applied to the vulva.—*Annales de Gynéc.*, February, 1884.

GALVANOPUNCTURE IN ANEURISM OF THE AORTA.—DR. FRANCESCO BRANCACCIO reports the case of a man, æt. 64 years, of intemperate habits, who complained of pain in the left anterior part of the chest, over the base of the heart, which radiated to the shoulders. The pain came on suddenly after a muscular effort, and was intermittent. Examination revealed a tumor, limited above by the upper border of the second rib, on the right by the sternum, on the left by the mammary line, and below was continuous with the heart. The diagnosis of aneurism of the ascending portion of the aorta having been made, it was determined to practise galvanopuncture. A fifteen cell Daniell's battery was used, two needles being carried into the sac through the third interspace to a depth of one inch and one-fifth, and an inch and a half apart. The first seance lasted sixteen minutes. In the afternoon the patient felt better, the tumor was smaller, the pulse, which had fallen from 118 to 90, was stronger, and the respirations were less frequent. Twenty days afterward the battery was again used, with twenty elements, for fourteen minutes. Altogether is was used four times, and the patient was completely cured.—*Revista Internaz. di Med. e Chir.*, February, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE . . . . . $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 19, 1884.

THE DISINFECTION OF THE SPUTUM OF TUBERCULOSIS.

AMONG many other valuable papers to be found in the second volume of the reports of the Imperial Board of Health of Germany just issued, under the editorship of Dr. Struck, is one by DRS. SCHULL and FISCHER upon the disinfection of the expectoration of phthisical patients. These experimenters treated the dried and moist expectoration by various germicides, with a view of determining those which would be at once most efficient and available in practice.

They ascertained, in the first place, that dried sputum, from 95 to 126 days old, was in all instances capable of producing tuberculosis in guinea-pigs inoculated with it. From this age its activity progressively diminished. Thus, of 3 guinea-pigs inoculated with sputum 143 days old, which was active at 95 days, 2 were infected. Of 3 pigs inoculated with the same sputum 186 days old, only 1 was infected, and of 3 inoculated with the same sputum 226 days old, none was infected. This activity they ascribed to the spores of the bacillus, since it has been experimentally shown, also, that the bacilli themselves are not to be found in sputum of this age.

We have not space to note the methods employed in treating sputum by the various substances and measures used, but pass directly to the results. Control-experiments were made in every instance with non-disinfected sputum, which was invariably found capable of producing tuberculosis.

1. Experiments with dried sputum. Almost all the methods used to disinfect dried sputum were successful. They included treatment of sputum from 98 to 143 days old, heated to from 212° F. to 266° F., sputum boiled for 5 minutes, and sputum treated for from 20 to 24 hours with corrosive sublimate 1 in 5000 and 1 in 2500; carbolic acid 1 in 100; liquor ammonia 16 in 100; caustic soda 1 in 100; iodide of pótassium 5 in 100; iodoform vapor, iodoform, iodine, and iodine vapor.

Steam, solution of arsenious acid, and dry iodoform vapor were alone unsuccessful.

2. The disinfection of fresh, undried sputum was not nearly so successful. The details of the experiments would occupy too much space, but of a large number of substances used in various degrees of concentration, including absolute alcohol, creasote water, the vapor of paper saturated with creasote, thymol in alcohol, arsenious acid, naphthalin water and vapor, solutions of iodide of potassium, bromide of potassium, bromine, iodine, iodoform, salicylic acid, carbolic acid, vapor of filtering paper saturated with oil of turpentine, acetic acid, spirit of hartshorn, chloride of sodium, aniline water, vapor of filtering paper saturated with aniline oil, caustic soda, and caustic potash, all failed to disinfect the sputa. Only the twenty hours' action of absolute alcohol, twenty-four hours' treatment with a saturated solution of salicylic acid, three per cent. solution of carbolic acid, acetic acid, caustic ammonia, saturated solution of aniline, and vapor of aniline oil, all acting through twenty hours, were effectual in destroying the activity of the sputum. The *two hours'* action of a five per cent. solution of carbolic acid, of a saturated solution of aniline, and of spirit of hartshorn did not destroy the infectious properties of the sputum.

Of the measures and substances which had appeared efficient in destroying the virulence of dried sputum, further experiments were made only with those which seemed available in practice, that is, dry and moist heat, corrosive sublimate, absolute alcohol, carbolic acid, and saturated aniline water. With dry heat, a specimen rich in spores, which five days previously had been allowed to dry upon a glass plate, was scraped off and a quantity, equal in bulk to a small bean, was enclosed in a capsule made of filter-paper, and further in a piece of linen three layers in thickness, and placed near the bulb of the thermometer in a drying-chest in which the temperature had been raised to 212° F., the object being to imitate the conditions under which clothing and other materials soiled with sputum would be disinfected. After an exposure of 15, 30, and 60 minutes respectively, the sputum was rubbed up with sterilized water in sterilized glass dishes, and injected with sterilized syringes into the abdominal cavity of guinea-pigs, controlled by experiments with non-disinfected sputum. The result proved that such exposure for an hour was insufficient to

disinfect the sputum with certainty, although more efficient than exposure for 30 minutes. Whence it was inferred that several hours' exposure would be effective.

It has been seen that an exposure of dried sputum to steam at 212° F. for 15 minutes, was not sufficient to sterilize it, but from 30 to 60 minutes was. So too fresh undried sputum after an exposure of 15 minutes to steam at 212° F., was rendered harmless. Similar results followed the boiling of sputum which control-experiments showed to be virulent.

The action of corrosive sublimate solutions upon the fresh, moist sputum was disappointing, and somewhat different from what might have been expected from recent experience. In the first place, solutions of 1 to 5000 of water, which seemed quite efficient in destroying the infecting powers of dried sputum, when added in the proportion of two parts to one of the sputum, making, therefore, a strength of 1 to 7500, were without effect. Then sputum treated with sublimate solutions 1 to 500, when injected into the abdominal cavity, caused death by poisoning. Finally, solutions of the strength of 1 to 1000 failed also to disinfect the sputum. Whence the experimenters concluded that corrosive sublimate is not adapted for disinfection of fresh sputum. In atttempting to account for the difference between these results and that of corrrosive sublimate upon dried sputum, they suggest that this had already lost some of its virulence before being treated, or that the corrosive sublimate being brought into contact with smaller particles of sputum, reached the spores more effectually, while in the case of the fresh sputum its contact produced a superficial coagulation which interfered with any germicidal action.

Further experiments with absolute alcohol showed that it could only be relied upon when used in the proportion of five times that of the sputum treated. So that it, too, is not practically available.

Carbolic acid, on the other hand, proved quite efficient, a 5 per cent. and 10 per cent. solution serving to disinfect an equal bulk of fresh sputum, although a 2½ per cent. solution was inefficient.

Saturated solutions of aniline water, containing 3.2 per cent. of aniline, served to disinfect sputum, when added in the proportion of ten times the quantity of sputum. While answering the purpose, therefore, it cannot be considered as suitable as carbolic acid, because it is at once more costly, and is further characterized by an odor even more unpleasant, while it is also more or less poisonous. *So that the best disinfectant for spit-cups used by phthisical patients would seem to be carbolic acid, with suitable solutions of which these utensils may be partially filled.*

So, too, the ordinary scalding and boiling to which the clothing of patients and others is subjected, is sufficient to destroy the virulence of tubercle bacilli; and as carbolic acid in the spit-cup will kill the bacilli expectorated into it, there should be no danger, if these simple precautions are taken, of disseminating phthisis through the sputum.

RUPTURE OF THE POPLITEAL VESSELS IN FORCIBLE EXTENSION OF ANKYLOSED KNEES.

THE treatment of fibrous angular ankylosis of the knee by forcible and sudden manual extension is liable to be attended with certain mishaps, of which the most common are separation of the condyles of the femur and the upper epiphysis of the tibia, and tearing of the skin of the popliteal space. Another risk, to which little attention has been directed in our text-books, is gangrene of the limb, from laceration or compression of the popliteal artery, but the accident is so rare that it was met with only four times out of five hundred and eighty cases in the hands of Bardeleben, Bauer, Busch, Hofmokl, B. Langenbeck, M. Langenbeck, Louvrier, and Nussbaum.

To these risks DR. SALZER, of Vienna, adds five examples of rupture of the popliteal vessels, the details of which may be found in the *Wiener Medizinische Wochenschrift*, Nos. 8 and 9, 1884, and of which three were under the charge of Billroth, and one each under the care of Gussenbauer and Nicoladoni. In all, the disease was of long standing. In three, the artery was completely ruptured, and in two, the lesion was incomplete and lateral. In four, the vein was also lacerated, and in three, the integuments were torn. Gangrene ensued in three cases soon after the procedure, and necessitated amputation through the thigh, of which one proved fatal from septicæmia. In the fourth case, gangrene set in after ligation of the ruptured artery and vein, and the patient succumbed from septicæmia after disarticulation at the hip-joint. In the fifth case, immediate amputation was followed by recovery.

With one exception, the vessels were surrounded by indurated tissues and were adherent to the posterior ligament of the knee-joint, which, as would naturally be expected in cases of chronic ankylosis, had undergone adapted shortening or contraction. Hence, when the ligament gave way under the forcible manipulations, the artery and vein necessarily met with the same fate. In such cases it would be far more wise not to resort to force, but to endeavor to correct the deformity by gradual and well-directed efforts at extension at several sittings. Should the limb grow pale and the temperature become lowered, there would be ground to suspect adhesion of the vessels to the posterior capsule of

the joint, when further manipulations should be temporarily abandoned.

THE AMERICAN MEDICAL ASSOCIATION.

The thirty-fifth annual meeting of the American Medical Association will soon be held, and our thoughts naturally turn to the results which have been achieved by the Association. While we recognize that much good has been the outcome of these annual gatherings of the profession, we feel that still more can be attained, and that it becomes the duty of the wise men who influence the action of the Association, calmly to consider how its utility can be enhanced, and what means can be employed to strengthen our great national organization. To attain its greatest scope of usefulness it must have the hearty sympathy and faithful coöperation of the whole profession; it must bind to it, not alienate from it, the workers in the ranks.

It is a matter of notoriety that there has been much dissatisfaction of late, with the results of the work of the Committee on Nominations, especially in regard to the selection of officers of Sections. We know that this Committee has a great deal to do; its members have to sacrifice, in large measure, not only attendance upon the general, but also upon the sectional meetings. Beside, they are solicited by this aspirant or that, or by friends of the self-proposed candidate, to give him a prominent office. Some of the scenes of solicitation, personal and persistent, that transpire at each meeting of the Association, make one blush for the modesty and humility of the medical profession. We are therefore inclined to be very charitable to the forty gentlemen to whom their respective State delegations have assigned the important duty of selecting officers for the Association and its Sections, yet we have not enough charity to say that their duty is uniformly, or even usually, well done.

The Nominating Committee is a large, unwieldy organization. From the number of offices to be filled, and because of the number of aspirants for office, an opportunity is given for combinations, for bargains, for that which is known among politicians as "log-rolling"—an opportunity which, judging by results, is rarely neglected. At the same time, the fact of the Committee being so large reduces to a minimum the responsibility of each member; and the saying of a well-known author, in commenting upon Solomon's adage,—"In a multitude of counsellors there is safety—yes, safety for the counsellors, but not for the counselled,"—is verified. Let one scrutinize, for example, the list of the officers of Sections for the last few years, and while he will find the names of some who are recognized authorities in their special departments, he will find the names of others who hold no such position, and of late the names of some who, it is alleged, have not even been, uniformly, upholders of the Code of Ethics of the Association, and of others, again, who are utterly unknown, either for good or evil, for learning or ignorance. Now, such appointments are disheartening to those upon whom the Association is compelled to rely for its scientific and practical work, and they weaken the general professional respect in which the Association is held.

Is there no remedy for this great evil? Would not the results be better if the work of the general Nominating Committee were confined to nominating the general officers, and if each Section were allowed to nominate its own officers? The members of a Section, it may be safely assumed, know better who are the representative men in their own special department, and who would be the most suitable and acceptable officers to guide their own deliberations, than a general Nominating Committee of forty or more members selected from the Association at large. Moreover, this plan commends itself to favorable consideration because it would do away with the probability—almost with the possibility—of making combinations and of log-rolling.

There can be no doubt that the unsatisfactory manner in which the Sections have been officered has been a large factor in promoting the growth of the numerous "American" special societies, which, of late, have grown up, and which, with the contemplated Society of Internal Medicine, cover the field of every one of the Sections. There seems to be no better way of discouraging the growth of these special societies, and of recalling their members into the general fold, than by giving to each Section of the Association the power of controlling its own organization, subject to the general laws of the parent body.

While, of course, a change from the present unsatisfactory way of making nominations cannot be made this year, yet we hope that steps to this end will be taken, and that it will be accomplished at the meeting to be held next year.

MARRIAGE AND MITRAL STENOSIS.

In a recent clinical lecture at *la Charité*, Dr. Landouzy stated that the mitral orifice is anatomically narrower in women. On the other hand, the hyperalkalinity of their blood leads to sclerosis. These conditions explain the frequency of mitral stenosis in women. Nevertheless, as long as the left auricle, says the *Journal de Médecine*, remains in good condition, the primary lesion makes but little progress; but when the great, vital test of pregnancy comes, there is danger.

Porak's statistics show that in gravido-cardiac disorders, as they are called, more than two-thirds of the cases are those of mitral stenosis, mitral insufficiency, or the two combined. Obstetricians are agreed in advising that a woman suffering with mitral disease, especially mitral stenosis, should not marry; or, being married, she should not have a child; or, having given birth, she should not nurse. A woman with mitral disease having been married, and becoming a widow without having borne a child, is in a most favorable condition if she remains content with widowhood. So, too, religious celibates who preserve their continence may have mitral stenosis, and live to the age of grandmothers.

Landouzy mentions the case of a young girl, who had been in the hospital under his care, and whom he had advised not to marry, but who disregarded his advice, married, became pregnant, and, after a miscarriage, died suddenly in an attack of asystole.

Of course, in cardiac disease, it is well to discourage marriage, but, in regard to such action, the old fable of Cupid being blind has countless illustrations, and at the bridal altar these very maidens, like other brides, deck themselves with orange flowers, the very symbol of fecundity — whether they know this or not — when they ought not to have a single pregnancy. But, when married, they are advised not to have children. How many women can control this matter? To avoid reproduction is very easy to advise, very difficult to do. Possibly it might be well to counsel these cardiopathics to prepare for marriage by first undergoing Battey's operation. But when the wife is not sterilized in advance, a similar proposition might be made to the husband, and in the day when our gentle sisters become professors of diseases of the male sexual organs, possibly normal orchidectomy may occupy as important a place in the surgical therapeutics of diseases of men as normal ovariotomy now does in diseases of women.

However, we are not sanguine that either plan of treatment for the prevention of pregnancy will be adopted; but we are inclined to think that germicide solutions may continue to be in demand by cardiopathic wives.

TRAUMATIC ANEURISM OF THE VERTEBRAL ARTERY.

In the *Archives of Medicine*, for April, 1884, may be found the report of a case of traumatic aneurism of the right vertebral artery high up in the neck, which is interesting, not only on account of the rarity of the lesion, but from the fact that DR. R. F. WEIR succeeded in effecting a cure by digital compression over the lower and anterior edge of the sac, in seven hours.

Dr. Weir tabulates eight similar cases, in which the error was committed of ligating the carotid artery. All proved fatal. He also refers to the case of Möbres, cured by the application of cold after pressure on the exposed external carotid had produced no effect on the tumor, and to that of Kocher, cured by graduated compresses of carbolized gauze acting on a pledget of splint, dipped in perchloride of iron, and crowded into the space between the transverse processes of the fifth and sixth cervical vertebræ. Hence, in the two cases in which the diagnosis was made, digital compression and direct compression have proved successful.

The great difficulty is in arriving at a correct diagnosis, which, Dr. Weir says, may be done by "carefully considering the effect of pressure on the carotid, not only above, but also on a line with the transverse process of the sixth cervical vertebra, or rather over the anterior or so-called carotid tubercle. Compression above this point affects, as a rule, the carotid artery only; over and below the transverse process compression will not only occlude the carotid but also the vertebral artery, which runs to its outer side. It must be remembered, however, that the vertebral, instead of entering the foramen in the transverse process of the sixth cervical vertebra, in its upward course sometimes remains exposed until it enters a higher foramen. To meet such possibilities, it has been suggested to isolate the carotid according to Rouge's plan, which is, with the sterno-mastoid relaxed, to grasp the muscle with the finger and thumb and to pinch the carotid between them. It is necessary also to keep in mind, in trying to effect vertebral compression, that the carotid tubercle is, according to Chassaignac, always from two to three inches above the clavicle. A traumatic aneurism whose pulsations are unaffected by compression of the carotid applied as above detailed, will be found to concern the vertebral artery."

In the treatment, ice and compression by bandages or the fingers having failed, the sac should be opened, the finger applied to the wounded artery until the clots are cleared away, and firm antiseptic plugging be resorted to, as was successfully done by Kocher in a case of aneurism, and by Kuester in two examples of wound of the artery.

OSMIC ACID IN NEURALGIA.

THE hypodermatic injection of from eight to fifteen drops of a one per cent. solution of osmic acid in peripheral neuralgia does not, upon further experience, fulfil the expectations which the first trials of Neuber led us to anticipate. Of 29 cases recorded by EULENBERG, in the *Berliner klinische Wochenschrift*, No. 7, 1884, there were only 7 cures, if

freedom from recurrence for periods varying from two to fourteen weeks be taken as the criterion of perfect recoveries. That the remedy does, however, exert a certain beneficial effect is shown by the fact that the pain disappeared without the employment of other remedial agents. Hence, it may be used, before resorting to anodynes, in examples of recent and uncomplicated forms of the affection, with some hope of success.

REVIEWS.

Hints on the Drainage and Sewerage of Dwellings. By William Paul Gerhard, Civil Engineer. 12mo. pp. 302, with 282 illustrations. New York: William T. Comstock, 1884.

Some years ago the author of this volume published in the fourth annual report of the State Board of Health of Rhode Island, a very satisfactory paper on "House Drainage and Sanitary Plumbing," which has since been used as the basis of a little manual on the same subject. The present work is an amplification of that paper, and is a highly creditable production. It is a *résumé* of the latest and most authentic information on the drainage and sewerage of dwellings, written in a plain and intelligent manner, and abounds in illustrations, which are indispensable in a work of this character.

The book opens with a statement of the general principles involved in house sanitation. The first chapters are devoted to an exposition of the common defects in the drainage and sewerage of buildings. In the remaining chapters, the principal features of a properly devised and well-constructed system of house drainage are plainly pointed out. This branch of the subject is discussed under the following headings: Drainage of Dwellings, Internal Sewerage of Dwellings, Description of Plumbing Fixtures, General Arrangements and Care of Fixtures, and External Sewerage and Disposal of Household Wastes.

The author properly condemns the covering of the top of the soil-pipe with a return-bend or ventilating cap, as a mistaken practice. The great importance of ventilating soil-pipes, traps, etc., is insisted upon, and the proper methods described. The description of traps is complete, but is rather wearisome by its length. It is hardly necessary to describe the numerous devices of this kind. A few of the best designs, illustrative of the objects to be secured, would have answered the purpose, without needless repetition of details. Privy-vaults and cesspools are rightly condemned as abominations which should never be tolerated where the water-carriage system is available. The author gives his preference to closets without any movable machinery, that is, the hopper closet and the wash-out closet. He insists that all plumbing fixtures should be, as far as possible, in plain sight. The open arrangement of the fixtures throughout the building is advantageous for cleanliness, and for ready inspection and ease in detecting faults, and in making repairs. He does not deem it essential to health that all these modern conveniences, if they are properly designed and well executed, should be banished from the main portion of the building.

The book is a faithful representation of the principles and practices advocated by the best authorities in the country, and will serve as a valuable guide to architects, engineers, physicians, and sanitarians, and especially to householders, whose duty and interest it is to have intimate knowledge of all matters pertaining to the drainage and sewerage of the dwelling.

The omission of an index is a most serious fault in any book, but it is especially embarrassing in one made up largely of details. The full table of contents cannot compensate for this error. The work of the publisher is fairly well done.

The Medical Directory of Philadelphia for 1884. Edited by Samuel B. Hoppin, M.D. 12mo. pp. 205. Philadelphia: P. Blakiston, Son & Co., 1884.

This conveniently arranged volume forms an excellent and accurate local medical directory. The collateral information, however, is rather meagre. The editor would have increased the usefulness of the book if he had given fuller information concerning the organization of, and rules governing admissions to, the hospitals, dispensaries, and other charitable institutions; and the value of the volume would have been also enhanced, without greatly increasing its bulk, by extending the directory to the whole State, as well as to the adjacent towns in New Jersey and Delaware.

SOCIETY PROCEEDINGS.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, February 25, 1884.

The Vice-President, Charles K. Mills, M.D., in the Chair.

Dr. Mills read a paper on

THE MCGINNIS CASE,

in which he summarized the facts indicating the insanity of McGinnis as follows: A bad family history; evidences of the monomaniacal character, as shown by a study of his life and present condition; the existence of a delusional state, and even of special delusions of a depressive and persecutory type; the presence of hallucinations of hearing and sight, the former being connected largely with persecutive ideas; some manifestations of religious monomania; a history of alcoholism, and the fact that his chief delusion (marital infidelity) was one often found in chronic alcoholic insanity.

Dr. Lambert Ott then reported a

CASE OF UNILATERAL SPASM, HEMIPLEGIA, AND APHASIA, FOLLOWING MEASLES IN A CHILD.

Boy, aged twenty-eight months, healthy and intelligent, talked well for one of his age. April 2d, he had a mild attack of mumps, and seven days later a well-defined but mild attack of measles. On the tenth day, he was well and laughing and playing in bed, but instead of the dull yellowish stains which remain after the papules of measles have faded, his skin was dotted with spots of a purplish hue. The same morning his mother

noticed a twitching of the muscles of the right eye and right side of face, and soon after similar movements of the right arm and leg. He remained conscious during the spasm, but was unable to speak. In an hour, the leg ceased to move, and was paralyzed. Half an hour later the arm-jerk stopped, and the limb lay powerless; the face movements continued only a few minutes longer, when the side of face was observed to be paralyzed. While the right-sided convulsive seizure was going on, the left arm and leg were affected with choreic movements, which subsided soon after right-sided paralysis was manifest.

Two hours after the first appearance of the spasm, the following condition was noted: Ptosis of right eye; no change in pupils, and no disturbance in movements of eyeballs. When he cried the right side of the forehead remained smooth, while the left was markedly corrugated; no paralysis of tongue, but complete aphasia. Motion in the right arm and leg completely paralyzed, sensation partially. He was conscious and drank water with very little difficulty. The left side of the body showed no disturbance of sensation or motion, except occasional choreic twitching. The dread the child had of strangers prevented an examination of the heart. Temperature 101°; pulse 120; respiration 20, and very irregular. Some bronchial catarrh.

Second day, temp. 102°, pulse 130, resp. 40; no vomiting; intelligence remained good; tongue dry; passed water and feces involuntarily. During the next six days his fever remained high, cough increased, and evidences of catarrhal pneumonia developed.

About the ninth day attention was called to a bulging of the right side of the chest, resembling the deformity produced by a large pleuritic effusion, with a marked lateral curvature of the spine, the convexity being toward the right side. Percussion of the lung of this side elicited hyper-resonance, and auscultation, normal breathing with prolonged expiration. The chest deformity was apparently due to contraction of the muscles of the left side. He had conjunctivitis of right eye and dribbling of saliva from the right angle of the mouth. Was very irritable, and often carried his hand to his head and moaned. Urine normal. The choreic movements of left side returned, but were not so marked.

In the second week the muscles of the face began to regain power. In the third week there was no marked change, except a peculiar swelling and tenseness of the paralyzed leg, which persisted four days and suddenly disappeared during one night; the next morning the leg was very flabby. Electro-muscular contractility was fair. In the latter part of the third week his head was drawn to the paralyzed side, the chin pointing to the left, showing the peculiar influence of the healthy sterno-mastoid and other neck muscles. The muscles of the right side of the neck were flabby; those of the left side were hard and tense. Lifting the head would place it erect, but when unsupported, would fall into its former position. In the fourth week movements were noticed in the arm, and in the fifth week the leg began to regain power. He was now, for the first time, using a few monosyllables, as *ma*, *pa*, etc. In the fourth month he walked fairly; used a few more simple words. In the sixth month, his general health was good, and he was talking more. His gait was fair, but he was unable to run. There existed a marked weakness of the flexor and extensor muscles of the anterior part of the right leg and of the extensor muscles of the right arm.

Dr. Ott regarded the case as one of embolism of the left middle cerebral artery, obstructing the first branch, called the frontal-external and inferior, which supplies the third frontal convolution; also the second and third branches, called respectively the anterior parietal of Duret, or the artery of the ascending frontal convolution of Charcot, and the posterior parietal artery, or the artery of the ascending parietal convolution of Charcot. These latter two branches supply the motor centres of the extremities (Ferrier). The fourth branch, which supplies the angular gyrus, was probably not obstructed, as vision remained apparently unimpaired. The motor centre of the facial muscles occupies a region in close proximity to that of the extremities, which is also supplied by branches of the middle cerebral artery.

The marked peculiarities in the case are as follows:

1. The age of the patient. 2. No loss of consciousness, which Hamilton says is the exception. 3. The disturbance of conformity of the chest, on the ninth day after the spasm. 4. The falling of the head to the paralyzed side twenty days after the spasm. Whenever he had a good night's rest, he was able to hold his head erect for two hours; after that time it lay to one side.

The order of recovery of the paralyzed parts was the reverse of the attack, and was as follows: the face, neck, and chest showed the first signs simultaneously, then the upper extremity, and next the lower extremity. When considerable power had been regained, quite noticeable yet was the weakness of the extensor muscles of the forearm, which gave the hand the peculiar position that resembles the wrist-drop of lead palsy.

Most interesting of all was the occurrence of aphasia. Here was an active little boy, who was suddenly stricken with unilateral spasm, followed by hemiplegia and a total loss of the power of speech. His intelligence did not wane one whit during the whole trouble, but it seemed as if he had to learn to talk over again. At no time did he misapply a word—as calling a chair a table. When once he knew a word and its application he always used it afterward. At this date (nine months after the attack) his speech is disconnected. If he desires to express a thought, he can make a good beginning, but is unable to finish. For instance, he wants to use the sentence, "Katie, get my hat in the other room!" he can only say, "Katie, get my hat ——," for the rest of the sentence he uses signs. His being unable to finish the sentence is not that he does not know the word "room," for, when used otherwise, he has no trouble in recalling it. When he uses three or four words in succession, his speech powers seem at an end.

DR. FRANCIS DERCUM said that he was inclined to regard the case as more likely to be one of hemorrhage than of embolism. It is well known that the miliary aneurisms described by Charcot and others occur sometimes in the very young; therefore, one of the conditions which lead to hemorrhage may be present in infancy. The absence of valvular disease of the heart was also against the idea of embolism. He thought that the symptoms presented by the case indicated a lesion of the internal capsule and basal ganglia, rather than of the convolutions. He referred to the more frequent

occurrence of hemorrhage in this region, and also to the wide extent of cortex that would have been required to be involved in order to explain the phenomena.

DR. MILLS agreed with Dr. Dercum that, from the history of the case, the absence of recognized heart lesions, and the age of the patient, the case was probably one of hemorrhage. He believed, however, that some of the facts indicated a cortical lesion. One of these was the existence of choreic movements on the side opposite that which was paralyzed. According to Duret, when irritative lesions of the cortex occur, they produce not only spasm on the opposite side of the body, but also may cause contraction or spasm on the same side, the result being brought about through irritation of the sensory nerves of the dura mater, which irritation is conveyed to the bulbo-medullary centres.

Dr. Mills referred to the completeness of the paralysis, as a matter of great interest in connection with the views of Broadbent as to the communication by commissural channels of those parts of the central nervous system which preside over movements of the two sides of the body which are associated.

DR. DERCUM said that the occurrence of choreic movement on the side of the lesion could be as well explained by the transmission of irritation by the commissural channels of the brain, as by the views of Duret.

DR. OTT closed the discussion, and said that in favor of the embolism view was the sudden appearance of the attack, and the symptoms which usually follow an embolus in the left middle cerebral artery. In favor of the view of cerebral hemorrhage was the disorganized condition of the blood, the result of measles, predisposing to such an occurrence.

DR. CHARLES K. MILLS then read a

NOTE ON THE USE OF NERVE PRESSURE FOR THE RELIEF OF HYSTERICAL CONTRACTURE.

In three cases he had resorted to strong presssure, applied, by means of the thumb or fingers, to the trunk of the nerve supplying the muscles affected by the spasm in contracture; in a case of hysterical spasmodic torticollis, and in one of hysterical contracture of the wrist and hand, the condition passed away, and remained relieved; in a case of long-standing contracture at the knees, under the effects of pressure on the sciatics the spasm disappeared, but recurred. The procedure was simple, and had value, both as a means of diagnosis and treatment. Whether the result was produced by mental effect, by causing a temporary paresis, or by the pain, he was not prepared to say.

DR. WHARTON SINKLER spoke of having used the method unsuccessfully in a case of facial spasm, which was not, however, hysterical in character.

Stated Meeting, March 24, 1884.

THE PRESIDENT, S. WEIR MITCHELL, M.D., IN THE CHAIR.

DR. MITCHELL, on taking the Chair, made some introductory remarks on

THE OBJECTS AND DUTIES OF A NEUROLOGICAL SOCIETY.

DR. SINKLER presented a patient suffering from

SPINAL ACCESSORY SPASM.

Anna B. K., aged forty-one, single. Has never enjoyed very good health, but has had no special illness. She has had neuralgic headaches for several years, and about three years ago had rheumatism in the left shoulder. In the spring of 1882 she noticed that, while sitting sewing, her head would turn toward the right shoulder. She could control the movement at first, if she directed her attention to it, but it soon began to be worse, and less under the influence of the will. In June or July, 1882, she became unable to restrain the movements. There was no pain in the neck or head, but she became nervous and irritable. There was a sense of discomfort on the top of her head. The use of her eyes seemed to make the movements more troublesome. Her general health has been fairly good, the appetite poor, and she has worried greatly. She was under Dr. Sinkler's care, at the Infirmary for Nervous Diseases, for several weeks in the spring of 1883, and various remedies were used. Galvanism and static electricity were faithfully applied, as well as massage. Hypodermics of atropia were given in the muscle affected, and the bromides and gelsemium were administered. There was no benefit apparent from the treatment.

She was readmitted a few days ago, and her present condition is as follows: She usually sits resting the right side of the face against her hand, to check the movements. The head is rotated to the right every few seconds, and turns more frequently if she is excited or nervous. The chin is turned strongly to the right, and the head is inclined slightly in the same direction. The head is not drawn back. After being held in this position for about two seconds, the spasm relaxes and the head becomes straight. She can keep the head quiet by resting it against some object, and sometimes will rest her head against the wall for this purpose. The left sterno-cleido-mastoid muscle is markedly hypertrophied, and is tender to handle. Pressure over the spinal accessory nerve does not arrest the spasm; it rather brings it on. There is pain at the insertion of the right sterno-mastoid muscle, but none in the left muscle. No contraction takes place in the trapezius muscle, and it is not hypertrophied. The voice is unchanged and there is no laryngeal spasm. The urine contains neither albumen nor sugar. The optic disks are nearly or quite normal. Vision R. $\frac{20}{XXX}$ to $\frac{20}{XL}$. She is nervous and inclined to be hysterical.

DR. DERCUM mentioned a case which was relieved by nitrite of amyl. He said, however, that the case was specific in nature. Iodide of potassium was afterwards given, with satisfactory results.

DR. MITCHELL believed that gelsemium, in exceedingly large doses, was the best remedy for such cases.

DR. A. J. PARKER made some remarks on

THE PRIMITIVE FISSURES OF THE FŒTAL BRAIN.

These fissures appear very early in fœtal life. He did not believe, with some, that they were due to hardening agents, as alcohol and chloride of zinc. He found that these fissures had certain mathematical relations to the brain itself. He regarded them as due to pressure, just as brain flexure is due to pressure. The brain grows under pressure; it tends to grow more rapidly than the skull. Fissures represent retarded growth.

THE PRESIDENT invited DR. GUY HINSDALE to exhibit some mounted specimens showing

THE LESIONS OF SNAKE VENOM.

The specimens were obtained in the experimental laboratory of Drs. Mitchell and Reichert, in the University of Pennsylvania, and illustrated the ecchymoses seen in the lungs of rabbits into whose jugular veins venom had been injected. The appearances are striking, the blotches of extravasation being in marked contrast with the surrounding lung tissue. The colors have been preserved by filling the large cells with a fluid composed as follows:

Glycerine, ...	Oss.
Dense solution of gum Arabic, . . .	Oj.
Saturated solution of acetate of potash, .	Oiss.

The cells are made by cementing to a square piece of plate glass a rubber ring, five inches high and five broad, covering the cell, when filled with the fluid, with a round cover-glass. These cells are four inches in diameter. The cement used is known as "Van Stan's Stratena," and being made with acetic acid, is not affected by the fluid of the cell. Before the rubber ring is fastened to the glass a triangular cork is cut in it, at two places, so that if the fluid becomes discolored, as in mounting specimens too quickly, the original fluid may be drained away and fresh fluid supplied. Large hypodermic needles and a syringe are of use in this operation. Air bubbles may also be removed in this way. The specimens exhibited had been mounted for one month, and they are apparently as fresh as ever.

The eight specimens exhibited the lesions of pure venom of the rattlesnake, the lesions of the three globulins, and the peptone which composes the poison.

THE MEDICAL SOCIETY OF THE STATE OF TENNESSEE.

Annual Meeting, held at Chattanooga, April 8 and 9, 1884.

(Specially reported for THE MEDICAL NEWS.)

THE fifty-first annual meeting of this Society was held at Chattanooga, and was a success, both in regard to the value of the papers read and the character of the representation.

APRIL 8TH, FIRST DAY. MORNING SESSION.

The Society met at the Hall of the Iron and Coal Association, at 11 A.M., and was called to order by THE PRESIDENT, DR. A. B. TADLOCK, of Knoxville; he appointed as a *Committee on Credentials*, Dr. B. B. Lenoir, Dr. W. F. Glenn, and Dr. D. D. Saunders.

Hon. Hugh Whiteside, Mayor of Chattanooga, then delivered an *Address of Welcome*.

PRESIDENT'S ADDRESS.

DR. A. B. TADLOCK then read his address, in which he ably discussed the general bearings of medicine and its relationship to the public. The necessity for legislation to prevent incompetent practitioners was considered, and it was stated that thirty-three of the States had such laws, whilst Tennessee had none.

AFTERNOON SESSION.

The Society was called to order at 2 P.M. On motion the President and Secretary were instructed to send greetings by telegram to the State Medical Association of Alabama, now in session at Selma.

DR. MASTERS, of Knoxville, then read a paper on *The Hygiene of the Eye*.

SECRETARY'S REPORT.

DR. C. C. FITE, of Nashville, then read his report, in which he called attention to the fact that this State was an asylum for travelling quacks. Most of our sister States have, by requiring diplomas and by strict examinations, shut out this horde of vampires, and so they are fattening on our people. We are maintaining our reputation for hospitality, and open wide our doors and welcome them. We, as a profession, he said, ask no protection; we ask no class legislation in our behalf, but for the ignorant masses we should demand protection of our law-makers, and if we unite our efforts we can do it almost without serious opposition.

The report was received and approved.

LICENSE TO PRACTISE.

DR. SAUNDERS moved that a committee be appointed to memorialize the Legislature to secure a law requiring registration and license to practise.

DR. GIBBS moved an amendment that the committee to be appointed prepare a bill, after comparison of all laws on the subject that are obtainable, and that this bill, so prepared, be discussed at an adjourned meeting to be held at Nashville on the first Tuesday in October.

DR. J. BERRIEN LINDSLEY spoke in favor of postponing action, and was in favor of the better organization of the profession in Tennessee.

Dr. Saunders's motion was then carried, after the amendment had been tabled.

Upon motion it was decided that the committee report to-morrow what plans they would pursue, and the following committee was appointed by the President:

Drs. D. D. Saunders, W. W. Taylor, Memphis; Drs. J. H. Van Deman, H. L. McReynolds, Chattanooga; Dr. R. F. Evans, Shelbyville; Dr. W. F. Clary, Bellbuckle; Dr. J. F. Grant, Nashville.

THE TREASURER, DR. ROBERTS, then made his report, which was referred to an Auditing Committee.

THE COMMITTEE ON CHANGES IN THE CONSTITUTION

then reported the results of their deliberations, and the afternoon session was devoted to its consideration.

The Constitution as amended was adopted. The most important change was one requiring five dollars as an initiation fee; two dollars as annual dues from members present at a meeting, and one dollar from the members absent, this entitling them to the *Transactions*.

The Board of Censors was abolished, and a Judicial Council, to be composed of the Ex-Presidents, was established.

APRIL 9TH, SECOND DAY. MORNING SESSION.

Papers were read by Drs. M. Davis, of Knoxville; H. Berlin, of Chattanooga; J. G. Sinclair, of Nashville; R. F. Evans, of Shelbyville; J. Blankenship, and Rathmell, of Chattanooga; A. J. Swaney, of Castalian Springs; W. M. Vertrees, of Nashville; and S. T. Hardison, of Lewisburg.

A telegram of thanks for greeting sent was received from the Alabama Medical Association.

AFTERNOON SESSION.

Dr. G. A. Baxter, of Chattanooga, being called upon by the Society, read a paper on *Uncomplicated Spinal Shocks*.

Dr. Glenn made some remarks upon *The McDade Treatment of Syphilis*, affirming that in his own large experience, and the Marine-Hospital experience of Dr. Douglass, in Nashville, it was a complete failure.

Dr. Saunders confirmed Dr. Glenn's conclusion.

STATE BOARD OF HEALTH.

Dr. J. B. Lindsley, President of the State Board of Health, read a communication from the State Board of Health upon the subject of vital statistics.

Dr. W. T. Hope offered the following motion: "*Resolved*, That the President appoint a committee of five on the State Board of Health, whose special duty it shall be to aid in the passage by the next General Assembly of a satisfactory law upon vital statistics." Carried.

ELECTION OF OFFICERS.

Dr. Hope nominated Dr. D. D. Saunders, of Memphis, for *President*, and he was elected by acclamation.

Dr. A. J. Swaney, of Middle Tennessee; Dr. W. T. Hope, of East Tennessee; and Dr. T. J. Reid, of West Tennessee, were elected *Vice-Presidents*.

A motion to proceed to the election of a *Secretary* was laid upon the table, as the Society was well pleased with its present Secretary, Dr. Fite. The Secretary having declined a reëlection, the Society retains him by having no one elected in his stead.

Dr. Deering J. Roberts was elected *Treasurer*.

EVENING SESSION.

THE COMMITTEE ON MEMORIALS TO THE LEGISLATURE presented the following:

To the Honorable Legislature of the State of Tennessee.

We, a committee appointed by the Tennessee Medical Society, at its last meeting at Chattanooga on April 8, 1884, beg leave to state that, from our personal knowledge, the people of this State, which you have the honor to represent, are being imposed upon in body and person, and in many instances permanently injured in health, and even killed, by ignorant and unauthorized persons who call themselves doctors, and who have no diplomas from recognized medical schools or certificates from authorized medical boards. We deem it our duty to make you conversant with these facts, that you may, as the regular and proper guardians of the peace, happiness, and lives of the people, take such legislative action as may protect your people from this source. So far as the regular profession of medicine is concerned, we wish you to understand that we ask your action not for ourselves, but in behalf of your own people, leaving us to take care of ourselves, which we claim to be able to do.

We would most respectfully suggest in the accomplishment of the above object that you may partially effect it by passing an act which prohibits the collection of medical fees by any other than a similarly legalized physician.

On motion, the report of the committee was received, and the committee continued.

THE COMMITTEE ON VITAL STATISTICS was appointed, as follows, at the request of the State Board of Health: W. T. Hope, Chattanooga; F. L. Sim, Memphis; R. Cheatham, Nashville; J. B. Murfree, Murfreesboro; J. S. Nowlin, Nashville, Chairman.

The Judicial Committee reported that the name of Dr. R. J. Hoyle, of Farmington, Tenn., be

DROPPED FROM THE ROLL OF MEMBERSHIP

on account of irregular practices. Dr. Hoyle was expelled, and the Secretary was instructed so to notify him.

Dr. W. W. Taylor introduced the following resolution in reference to

COUNTY MEDICAL ORGANIZATION:

Resolved, That a committee be appointed on county medical organization, to consist of three members, one from each section of the State. Adopted.

Drs. H. L. McReynolds, of Chattanooga; A. J. Swaney, of Castalian Springs, and W. W. Taylor, Chairman, of Memphis, were appointed the committee.

SIMS MONUMENT FUND.

The following resolution of Dr. P. D. Sims was then adopted:

Resolved, That the Tennessee State Medical Society appropriate to the Marion Sims Monumental Fund the sum of fifty dollars, and that the Treasurer of the Society be and he is hereby instructed to forward from the fund of the Society this amount to Dr. Maury, of Memphis, the custodian of said fund in Tennessee.

The following were appointed by the President

DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION:

Drs. Duncan Eve, of Nashville; W. F. Glenn, of Nashville; C. C. Fite, of Nashville; J. B. Lindsley, of Nashville; R. A. Hardin, of Savannah; W. A. H. Coop, of Savannah; J. G. Sinclair, of Nashville; G. B. Thornton, of Memphis; D. D. Saunders, of Memphis; A. J. Swaney, of Castalian Springs; R. F. Evans, of Shelbyville; W. T. Briggs, of Nashville; W. R. Townsend, of South Pittsburg; W. M. Vertrees, of Nashville; A. B. Tadlock, of Knoxville; J. H. Van Deman, of Chattanooga; G. A. Baxter, of Chattanooga; W. G. Bogart, of Sweetwater; H. H. Loveman, of Chattanooga.

The Society then adjourned to meet on the second Tuesday in April, 1885, at Nashville.

CORRESPONDENCE.

THE DISCOVERY OF THE SWINE-PLAGUE MICROCOCCUS.

To the Editor of The Medical News.

Sir: In your issue of April 5th is a communication from Dr. Gradle, of Chicago, which contains some rather surprising assertions, coming, as it does, from a man of scientific pretensions, and the author of a work on the "Germ Theory of Disease." As this is neither the first nor the second time that Dr. Detmers and his friends have accused me of injustice and misrepresentation, I propose in this communication to show what grounds these gentlemen have for making such serious charges, and I hope to make the matter so plain that even they may be satisfied. Fortunately, the points at issue are matters of record, and the original evidence

can be consulted by anyone who desires the facts, uncolored by the views of interested parties.

In my article in *Science* (vol. iii. p. 155), I endeavored to give references for all dates and all important statements that were made. If any of these were inexact, I shall be happy to correct them when the error is pointed out; but I cannot accept a general assertion of injustice and untruth as sufficient basis for modifying conclusions that were only given to the public after mature consideration.

Dr. Gradle has made a few definite statements of his own, however, to which I wish to call attention. He admits that micrococci had been described before Detmers' investigations were made; and he might have added that bacilli had also been described, and the disease attributed to them. What evidence there was at the time indicated that the disease was caused by a bacillus? Klein had just announced that this was the case, and had given careful descriptions and drawings of the organism, and a long series of experiments which he considered conclusive.

Detmers, coming immediately after Klein, also asserted that the organism was a bacillus, largely, as he has since informed us (*American Naturalist*, xvi., 1882, p. 198), because of Klein's investigations; but he so completely failed to give any credit to Klein that no one would have surmised from his original reports that there was such a man in existence. It was not until it was found necessary to get rid of the bacillus theory that Klein was referred to at all, and then only to make him responsible for the error.

It is admitted by Dr. Gradle that Dr. Detmers committed "a mistake in the description of, and name given to the parasites." Dr. Gradle does not seem to regard this as a very serious error; but he forgets that the question at issue at that time was as to whether this organism was a bacillus or a micrococcus. Dr. Detmers decided that it was a bacillus, and since it has turned out to be a micrococcus, he is naturally very anxious to have us believe that he meant micrococcus all the time. To explain his mistake it has been necessary to tell us that his lenses were so insufficient that he could not tell a micrococcus chain from a bacillus rod; and yet on the same page with this admission Dr. Gradle has the assurance to assert, what Dr. Detmers has asserted many times before, viz., that Dr. Detmers invariably found a specific kind of bacteria. These gentlemen seem to forget that a lens which is insufficient to discriminate between a micrococcus and a bacillus must fail still more disastrously if the attempt is made to discriminate between the different varieties of micrococci or of bacilli. As a matter of fact, however, I think few microscopists who have worked with Hartnack objectives will be willing to accept the conclusion that these are as imperfect as Dr. Detmers would have us believe. Indeed, Dr. Detmers never hinted at this himself until it became necessary to explain the radical mistake referred to; on the contrary, he went so far as to examine the dew on the grass with this same objective, and asserted most positively that he found in it the specific bacilli which he invariably found in the blood and other material from sick hogs! (Special Report, No. 12, p. 41.) When it is remembered how very difficult it is, how impossible I might say, to recognize many of the different species of bacteria even with the very best objectives that are now made, the absurdity of claiming to do this with a lens under which a micrococcus chain looked like a bacillus rod, becomes very striking.

Further on, Dr. Gradle says, "The error in the botanical description was hence corrected the following year (Special Report No. 22, p. 60)." Referring to this report, I beg the reader to recall the drawings, which are intended to be faithful representations of what he saw. Take figures 1, 2, 3, 4, 6, 10, 11, 12, 15, 16, 17, and tell us how in the world the rod-shaped objects shown in them can be classed as micrococci? Take central Fig. 3, in the first third of the plate, or the large central unnumbered figure in the middle of the plate, each representing the supposed bacteria of swine-plague, and if the organisms shown in these are not typical bacilli, then I would like Dr. Gradle to explain what they are, and to give some authority for naming them differently. If they were considered to be micrococci, why do we find under nearly every drawing the words bacilli or rod-shaped schizomycetes? Surely micrococci are not rod-shaped. It is to be remembered that at the time this report was made, Dr. Detmers possessed a Tolles lens, and that, consequently, the defective-objective excuse no longer applies. In this connection, I beg to call attention to a sentence on page 59, Special Report No. 22, which both Detmers and Gradle appear to have overlooked. It reads as follows: "The objectives used were a one-ninth imm., or No. 8 Hartnack [the same objective used in the investigations of the preceding year, D. E. S.], a one-sixteenth imm., or No. 10 Hartnack, and a one-tenth oil or balsam index imm., of Tolles, of recent make and superior quality. The results, in all cases, have been essentially the same."

We will now briefly consider the evidence which, it is claimed, Dr. Detmers furnished in his first report to show that swine-plague was caused by micrococci. Of course we do not forget in the meantime that the bacteria found were then called bacilli, and described as rod-shaped; and some of my readers will doubtless wonder how Dr. Gradle can now be so sure that they were micrococci; it is a difficulty which he can doubtless explain, but which is rather more than I care to grapple with. Dr. Gradle endorses these experiments in the following unqualified terms, to which I call special attention, because I want to show how good a judge he is of this class of investigations, of which he seems to be making a specialty: "Since all precautions necessary to render such experiments faultless were fully carried out, no flaw can be detected in Detmers' demonstration of the bacterial origin of the disease." (Dr. Gradle's letter in THE MEDICAL NEWS, p. 401.)

The first experiment was a cultivation of the germs, and I think the reader will be interested in knowing how this was done. "On September 23d," we are told, "Prof. Burrill charged two drachms of fresh cow-milk with a mere speck, smaller than a pin's head, of a decaying morbid growth, or ulcerous tumor of the cæcum of pig No. 5, and kept the vial well closed, at a temperature of 92° F." (Special Report No. 12, p. 37.)

Most investigators, when they attempt to make a cultivation, use some precautions to obtain their virus in a condition of purity. In this case a decaying, ulcerous tumor of the intestine, which any one of experience knows would be certainly contaminated with the bac-

teria of putrefaction, was the material chosen. Suppose, for the sake of argument, it was originally free from such contamination, can any one imagine how it could be carried to the laboratory and placed in a cultivation apparatus without coming in contact with the numberless germs found everywhere in the air? Then comes the cultivation liquid, fresh cow-milk. No attempt to sterilize—no means of getting rid of the germs which fall into this liquid during the process of milking, or which always adhere to the vessels into which it is received. What wonderful precautions! Then the cultivation apparatus—a vial! Surely no comments can add to the force of the author's own language. This virus was not carried to a second cultivation, but a single animal was inoculated from the first. Now, admitting that the pig inoculated contracted swine-plague from this milk, what is there to show that the virus multiplied? Is it not just as likely that a simple dilution to that extent would have produced the same effect? I have shown that chicken-cholera virus might be diluted to seventy thousand times its volume and still be active. and Davaine long before demonstrated the activity of septicæmic virus when diluted with a hundred million or even a trillion times its volume. Is there anything unreasonable in concluding that these two drachms of milk might have become virulent by the simple dilution of the added virus?

This milk contained bacilli figured as distinctly as it is possible to draw such organisms, and which any one can see were neither "serrated" nor "moniliform" by examining drawings 3 and 4 under Section 3 of the plate accompanying Dr. Detmers's report in Special Report No. 12.

The second experiment is even more remarkable in some respects. The idea was to remove the bacteria by filtration from the virus and show that the liquid freed from these was harmless. To this end blood serum from the diseased lungs of a pig was filtered through eight filters on October 8. It still contained "bacillus germs." October 9, the filtrate was filtered again through two filters. October 14, the same filtrate was filtered through four papers. As no bacteria could be found in the filtrate after the last filtration, the liquid was used for the inoculation of one pig. No disease resulting, it was concluded that the active principle of the virus was the bacteria which in this case had been filtered out.

Now a certain number of hogs are insusceptible to cholera just as a certain proportion of other animals and men are insusceptible to most other contagia. Suppose the single pig used for this experiment had been one of the insusceptible ones, what would the experiment have proved? Again, Dr. Detmers tells us that "In all animal substances the bacilli and their germs are destroyed, or at least disappear, as soon as putrefaction sets in." (Special Report, No. 22, p. 30.) The serum in the experiment in question was preserved in a bottle for seven days, being repeatedly exposed to the air in the meantime during filtration. And as this occurred during the warm weather of the second week in October, is it out of reason to ask if in this case putrefaction might not have had something to do with the loss of virulence? I know from experience that this virus frequently loses its activity from putrefaction in less than a third of the time which it was kept in this instance.

These are the experiments which Dr. Gradle so confidently refers to as having been made with all necessary precautions, and to be without flaw! How either of these experiments indicate that the germ is a micrococcus rather than a bacillus is a question which I leave for Dr. Gradle to clear up; it certainly is beyond the reach of ordinary mortals.

Another assertion is as follows: "The description of the characteristic mode of grouping, and the drawing of the parasites in the first two reports, as well as in the later one of 1880, show that Dr. Detmers really dealt with the same micro-organisms in all these instances." This statement is diametrically opposed to the facts. The bacilli figured in Dr. Detmers' first two reports are no more like the micrococci which he described later than a bat is like a ball, nor is there anything characteristic in any of the groupings. All of Dr. Detmers' drawings and conclusions show unmistakably that his material was contaminated with septic bacteria of various kinds. The micrococci of swine-plague are motionless micrococci, with nothing in their form, size, or grouping to distinguish them from some other varieties of micrococci. And when Dr. Detmers tells us that they develop into a dumb-bell organism with a flagellum, and that they swim about the field with an independent motion, we cannot avoid thinking of bacterium termo. When he goes further, and tells us that he has always seen rods, and even helobacteria, and believes his micrococci develop into these, I am perfectly satisfied in my mind that his virus was not pure. If Dr. Gradle wishes to advocate Detmers' views—that a micrococcus may exist in all the different forms usually ascribed to the various genera of bacteria, excepting the single one of spirillum, he is at perfect liberty to do so; but surely those of us who know how ridiculous such views are in the light of modern science, have an equal right to reject them.

The question, however, is not whether Dr. Detmers saw and described bacilli or micrococci—both of these forms had been described and figured before his investigations. His only claims to originality can be in proving that one of these organisms is capable of producing the disease. This he never did, nor has he ever made any experiments which throw the least light on this contested question. His methods of cultivation are insufficient from every standpoint, and cannot, by any ingenuity, be made to touch the points claimed in such exaggerated language by Dr. Gradle. In the very last paper which Dr. Detmers has written on the subject, he expresses the view which he has clung to from the first —that the micrococci, the swimming, dumb-bell-shaped organisms, the rods, and the helobacteria, are all one and the same organism, in different stages of existence. (*American Naturalist*, March and April, 1882.) A single pure cultivation would have revealed to him this radical mistake; and the fact that he still holds this error is proof positive that he never made such a cultivation. If, then, he was never able to separate the micrococci from the rod-shaped bacteria—and holding, as he does, that both are one and the same organism he cannot reasonably make such a claim—then it requires no other evidence to show that he could not possibly have proved either the one or the other of these forms to be the real cause of the disease.

Washington, D. C., April 3, 1884

NEWS ITEMS.

NORTH CAROLINA.

From our Travelling Correspondent.

SHAW UNIVERSITY is situated in Raleigh, N. C., and an account of a recent visit to it may interest your readers. It is one of a dozen similar institutions founded over the South by the American Baptist Home Missionary Society for the education of the negroes. It has an industrial, normal, academic, theological, and medical department, to which a law department will shortly be added. Four hundred and fifty students, of both sexes, and six large buildings, on a campus of twelve acres, attest its success.

The want of colored medical men for their own race has been widely felt in the South, and even the State Legislature has set its seal of approval upon this effort to provide for the want by giving the land upon which one of the two medical buildings stands.

The medical department is only in its second year, and has fourteen students. The Faculty at present consists of three professors, one from Vermont, and the other two, leading practitioners in Raleigh. They have wisely decided that, in view of the limited early education of the negroes, the medical course shall be four years, both to give a thorough graded course, and the opportunity to study Latin and other branches in the academic department.

If the black man is to enter medicine, he must expect just what the white man does—a fair fight and no favors. If inferior in education and skill, he will go to the bottom; if superior, he ought to get to the top. Hence "thoroughness" is the especial aim at Shaw. And the examinations I heard were admirable. One student went through nearly every point in the sphenoid bone with but two or three mistakes; another gave a careful and intelligent account of the histology of bone; and another of the kidney. Altogether, the anatomical examination would have done credit to any of the schools in your own city. The other examinations I attended were in physiology and practice, and were nearly as good as the first.

Clinical facilities are as yet wanting, but it is proposed to build a pavilion ward of twenty beds very soon, and the city has agreed to furnish all the medical supplies needed for it. This will enable students also to have some clinical facilities in the medical specialties, to which the fourth year is entirely given up.

Having begun so lately, the school is almost destitute of library, museum, and other means of illustration, and any of your readers would do a good service by sending contributions to any of these departments. They have some of Auzoux's models, an excellent microscope, and a fair, though limited, chemical equipment.

The faculty is united, progressive, and laborious. The students are intelligent, enthusiastic, and industrious, and in their earnest struggle for an honorable means of self-support, they ought to receive good wishes and a hearty support.

YELLOW FEVER AT HAVANA. — Sanitary Inspector Daniel M. Burgess, U. S. M. H. S., stationed at Havana, reports 502 deaths, from all causes, in that city during the month of March last. Of these 9 were from yellow fever, 6 from typhoid, and 9 from "pernicious" fever. Of the 9 from yellow fever, 7 occurred in the Military Hospital, and 2 among civilians. He says there were 16 cases of yellow fever at the date of his report (April 3); but for the last month it has not been malignant in character, a very large percentage recovering. He adds: "The diagnosis 'pernicious fever' is made in this city very carelessly and loosely, in many cases by the physicians here, and though I have no doubt it usually is intended to convey the idea of a disease of malarial or paludal origin, I am nevertheless confident that not an insignificant proportion of such cases, and particularly deaths, are true yellow fever."

THE UNITED STATES AT THE INTERNATIONAL SANITARY CONGRESS. — Notification has been received by Surgeon-General Hamilton, through the Secretary of the Treasury, that the Secretary of State has designated Prof. C. F. Chandler, of Columbia College, New York City, as Honorary Commissioner of the United States to the International Sanitary Congress, to be held at the Hague, on the 21st–27th of August, 1884.

AMERICAN SURGICAL ASSOCIATION.—The next meeting of the American Surgical Association will be held on April 30th, and May 1st, 2d, and 3d, in the Lecture-Room of the National Museum, Washington.

The following papers will be presented:

Dr. S. D. Gross, Phila.—Wounds of the Intestines.

Dr. Moses Gunn, Chicago—The Philosophy of Manipulation in the Reduction of Hip and Shoulder Dislocations.

Dr. J. Collins Warren, Boston—The Healing of Arteries after Ligature.

Dr. J. C. Hutchison, Brooklyn—Transfusion.

Dr. S. W Gross, Phila.—Gastrostomy, Œsophagostomy, Internal Œsophagotomy, Combined Œsophagotomy, Œsophagectomy, and Retrograde Divulsion in the Treatment of Strictures of the Œsophagus.

Dr. J. W. S. Gouley, New York—Some Points in the Pathology and Surgery of the Prostate.

Dr. David W. Cheever, Boston—Some of the Dangers and Disadvantages of Anæsthetics.

Dr. Basil Norris, Surgeon U. S. Army, Washington—Extirpation of the Tongue.

Dr. C. H. Mastin, Mobile—Prostatic Calculi, Cases and Specimens.

Dr. Henry F. Campbell, Augusta, Ga.—Artificial Respiration in the Sitting Position.

Dr. P. S. Conner, Cincinnati—Traumatic Cephalhydrocele.

Dr. Donald Maclean, Detroit—Clinical Notes.

Dr. J. Ewing Mears, Philadelphia—A Contribution to our Knowledge of the Pathology of Trifacial Neuralgia.

Dr. David Prince, Jacksonville, Ill.—Unsettled Questions in Relation to Injuries to the Head.

Dr. George W. Gay, Boston—Tracheotomy in Croup.

Dr. Stephen Smith, New York—Does the Practice Keep Pace with the Science of Surgery?

Dr. John B. Roberts, Philadelphia—The Localization of Perinephric Inflammation by Means of Chemico-anatomical Study.

Dr. William A. Byrd, Quincy, Ill.—Trephining for Insanity Following a Depressed Fracture of the Skull.

Dr. W. S. Tremaine, Surgeon U. S. Army—Suprapubic Lithotomy.

Dr. L. McLane Tiffany, Baltimore—Ligation of Common Femoral Artery.

Dr. John S. Coleman, Augusta, Ga.—The Multiple Wedge Principle in the Treatment of Organic Strictures of the Urethra.

Dr. W. W. Keen, Philadelphia—A Case of Dermoid Cyst Opening into the Bladder in a Male.

Dr. N. Senn, Milwaukee—Experimental Researches on Cicatrization in Bloodvessels after Ligature.

Dr. John H. Brinton, Philadelphia — Intrauterine Compound Fractures.

Dr. Joseph W. Thompson, Paducah, Ky.—Surgery of the Hand, Especially as Applied to Railroad Injuries.

Dr. John A Comingor, Indianapolis — Anæsthesia and Plaster-of-Paris Bandage in the Treatment of Sciatic Neuralgia.

Dr. B. A. Watson, Jersey City — An Experimental Study of Anæsthetics.

Dr. E. H. Gregory, St. Louis—Subject not announced.

Dr. W. W. Dawson, Cincinnati — Subject not announced.

Dr. Charles B. Nancrede, Philadelphia—Surgical Interference in Cerebral Abscess.

Dr. William T. Briggs, Nashville — Trephining for Epilepsy.

The South Carolina Medical Association will hold its annual meeting at Florence on Thursday, the 22d inst.

The Texas State Medical Association will meet in annual session at Belton on the 22d of April.

The Medico-Chirurgical Faculty of Maryland will hold its annual meeting in Baltimore on Tuesday next. The annual address will be delivered by Dr. William Pepper, on "Some Practical Views on Dietetics in Disease," on Wednesday at 1 P.M.

Canada Medical Association.—The next meeting of this Association will be held in Montreal on August 25th, 26th, and 27th; and the meeting of the British Association for the Advancement of Science begins in that city on August 27th.

The Kansas City Medical College held its fifteenth annual commencement on March 5, and the degree of M.D. was conferred on seventeen candidates.

The University of Kansas City held the third annual commencement of its medical department on March 13, and the medical degree was conferred on fourteen candidates.

The Foot and Mouth Disease in Kansas.— Dr. D. E. Salmon, of the U. S. Department of Agriculture (Veterinary Division), reports that, from personal examination in Kansas, he saw nothing to indicate foot and mouth disease. The feet were separating—sometimes half way between fetlock and hock—as a consequence of dry gangrene. The mouth symptoms were very slight or entirely absent; when present they were of the nature of erosions—he saw no vesicles. He attributed the disease to ergot, of which there was a large quantity in the hay. This conclusion is contested by some, and experiments are now under way to show whether or not it is contagious.

International Health Exhibition, London, 1884.—A somewhat novel feature in connection with the exhibition this year will be the establishment of a library and reading room, a home for which the executive council have assigned in a large double room in the Albert Hall, overlooking the conservatory. Steps have been taken to secure a representative collection of works on vital statistics; of reports and regulations relating to public health; of regulations with reference to injurious trades and of works thereon; and of reports, statistics, and other works on the science of education. Foreign powers have been invited to lend their coöperation in this effort to create an international library of works of reference bearing on the two divisions of the exhibition, and several responses have already been received. India and the colonies have also been asked to contribute towards the same end. Publishers and authors have likewise been invited to forward copies of their works. In addition to the library of reference, there will be a reading room, to which the current numbers of periodical publications of a sanitary or educational character will be admitted. All books and periodicals sent to the library and reading room will, under certain regulations, be arranged for the use of visitors, and not merely for exhibition. The books will be submitted to the jurors, and a full catalogue will be issued. All parcels for the library and reading room should be addressed, carriage paid, to the Secretary of the Library Sub-Committee, Royal Albert Hall, London, S. W.

Health in Michigan.—Reports to the State Board of Health for the week ending April 5, 1884, indicate that inflammation of the bowels, bronchitis, and diarrhœa have increased, that pneumonia has considerably decreased, and that scarlet fever, inflammation of the brain, and measles have decreased in area of prevalence.

Compared with the average for the month of March in the preceding six years, cerebro-spinal meningitis was more prevalent, and pneumonia, rheumatism, and remittent fever less prevalent in March, 1884.

Including reports by regular observers and others, diphtheria was reported present during the week ending April 5, and since, at ten places, scarlet fever at seventeen places, and measles at eight places.

Obituary Record.—Pliny Adams Jewett, of New Haven, died of pneumonia, in Providence, on April 10th, aged seventy-two. He received his literary education in Trinity College, and his medical education at Yale College and in Paris. After studying in Paris he settled in New Haven. Subsequently he resided in Aiken, S. C., for two years, and then returned to New Haven.

Dr. Jewett made a specialty of surgery, and for thirty-five years has been attending surgeon at the New Haven Hospital. In 1856 he was elected Professor of Obstetrics at Yale College, and held this position for twelve years. During the War of the Rebellion he was a surgeon of volunteers, and was afterwards promoted to a colonelcy for meritorious service; he organized and had

charge of Knight's U. S. Army General Hospital, at New Haven, from 1862 to 1865.

NOTES AND QUERIES.

A YEAR'S WORK IN OVARIOTOMY.

To the Editor of THE MEDICAL NEWS.

SIR: In your last issue Mr. Lawson Tait says "that Professor Goodell is right in pointing out that Dr. Sutton's words are likely to give rise to a misunderstanding." Again, he says: "In order that the nature of my work may not be misunderstood, kindly allow me to say that last year I removed eighty-two tumors of the ovary and parovary," etc. Dr. Goodell made use of my remarks, before the Gynecological Society, in reference to Mr. Tait. I said, "so far as Mr. Tait is concerned, he does not remove many large tumors, those which weigh from sixty to sixty-five pounds with extensive adhesions." Such was the fact, which I observed in Mr. Tait's work in the summer of 1882. Mr. Tait cites his work in 1883. Of this work he says: "Two of these were very small dermoid cysts. The remaining eighty had an average weight of about twenty-seven pounds, the largest being about one hundred and twenty pounds, and the smallest eleven pounds."

Eighty tumors averaging twenty-seven pounds give a total of twenty-one hundred and sixty pounds; now if nine of these eighty tumors weighed sixty-five pounds each, and you add one tumor of one hundred and twenty pounds weight, you have seven hundred and five pounds to deduct from the aggregate weight of twenty-one hundred and sixty pounds, which he admits; this gives you the aggregate weight of the remaining seventy tumors at fourteen hundred and fifty-five pounds, an average of about twenty pounds to the tumor. Certainly, a class of twenty pound ovarian and parovarian tumors is rarely a bad one. But unless at least ten of these cases exceeded sixty pounds, my remark still holds good, viz., that *he does not remove many large tumors, those which weigh from sixty to sixty-five pounds with extensive adhesions.* I mean no disparagement of his work, its results are superb.

Very respectfully yours,

R. S. SUTTON, M.D.

PITTSBURG, April 15, 1884.

LIME INHALATIONS IN CROUP.

To the Editor of THE MEDICAL NEWS.

SIR: *Apropos* of lime inhalations in membranous croup, etc., a subject now being discussed in your columns, it might be well to call the attention of your readers to the following, from p. 549 of *Diseases of Children*, by J. Lewis Smith, M.D., of New York, fifth edition, 1881:

"It has long been known that the vapor of slaked lime is an active solvent of pseudo-membranes, but the manner in which it has frequently been employed is inefficient. Many physicians place the unslaked lime in pans or dishes, add water to it, and place the child so that it inhales the vapor as it rises. This is little more than the inhalation of steam, as anyone may satisfy himself by holding a mirror or pane of glass over it, when he will perceive only a very slight deposit of lime on the glass. The proper way to employ it is with the atomizer," etc.

I think Prof. Smith deserves priority in this matter over some more recent writers. I have had no experience with lime in croup, but can attest the efficacy of a two per cent. solution of liquor potassæ, applied by means of the steam atomizer, having used it in several cases with most gratifying results.

Respectfully,

G. E. COWLEY, M.D.

GLASSVILLE, Mo., April 9, 1884.

CORRIGENDUM.

IN our issue of last week, page 418, second column, fifth line, for "possible" *read* "impossible."

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 8 TO APRIL 14, 1884.

SMITH, JOSEPH R., *Major and Surgeon.*—Directed to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held in Washington, D. C., on the 6th of May, 1884, and on the adjournment of the Association to return to his proper station (San Antonio, Texas).—*Par. 7, S. O. 81, A. G. O.*, April 8, 1884.

BAILY, JOSEPH C., *Major and Surgeon.*—Leave of absence extended three months.—*By Par. 8, S. O. 83, A. G. O.*, April 10, 1884.

PILCHER, JAMES E., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Camp Poplar River, Montana.—*Par. 2, S. O. 37, Headquarters, Department of Dakota*, April 7, 1884.

WALES, PHILIP G., *First Lieutenant and Assistant Surgeon.*—Ordered to report to the Commanding General Department of the Columbia, for assignment to duty.—*Par. 11, S. O. 84, A. G. O.*, April 11, 1884.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE-HOSPITAL SERVICE, FROM JANUARY 1 TO MARCH 31, 1884.

FESSENDEN, C. S. D., *Surgeon.*—To proceed to Cairo, Illinois, and Memphis, Tennessee, as Inspector, March 5, 1884.

PURVIANCE, GEORGE, *Surgeon.*—Granted leave of absence for thirty days, February 16, 1884.

SMITH, HENRY, *Surgeon.*—To rejoin his station at Norfolk, Virginia, March 7, 1884.

IRWIN, FAIRFAX, *Passed Assistant Surgeon.*—Relieved from duty at Norfolk, Virginia; to assume charge of St. Charles Quarantine Station, March 7, 1884.

CARMICHAEL, D. A., *Assistant Surgeon.*—To report to Surgeon Purviance for examination for promotion, March 5, 1884.

ARMSTRONG, S. T., *Assistant Surgeon.*—To report to Surgeon Fessenden for examination for promotion, March 5, 1884.

BENNETT, B. H., *Assistant Surgeon.*—Leave of absence extended ten days, January 18, 1884.

AMES, R. P. M., *Assistant Surgeon.*—Detailed for temporary duty on relief boat (Ohio River Flood Sufferers), February 16 and March 1, 1884.

DEVAN, S. C., *Assistant Surgeon.*—Upon expiration of leave of absence, to proceed to St. Louis, Missouri, for temporary duty, February 6, 1884.

KALLOCH, P. C., *Assistant Surgeon.*—To proceed to Charlestown, South Carolina, for temporary duty, February 1, 1884.

BEVAN, A. D., *Assistant Surgeon.*—Granted leave of absence for seven days, March 13, 1884.

WASDIN, EUGENE, *Assistant Surgeon.*—Granted leave of absence for fifteen days, March 4, 1884.

BATTLE, K. P., *Assistant Surgeon.*—To proceed to New York, N. Y., for temporary duty, February 4, 1884.

RESIGNATION.

COOKE, H. B., *Passed Assistant Surgeon.*—Resignation accepted by the Secretary of the Treasury, to take effect February 5, 1884. January 31, 1884.

APPOINTMENT.

BATTLE, KEMP P., M.D., of North Carolina, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, February 2, 1884.

PROMOTIONS.

CARMICHAEL, D. A., *Passed Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from March 1, 1884. March 18, 1884.

ARMSTRONG, S. T., *Passed Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from April 1, 1884. March 28, 1884.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

CHRONIC NASAL CATARRH.

Two Clinical Lectures,
Delivered at the College of Physicians and Surgeons, New York.

BY GEORGE MOREWOOD LEFFERTS, M.D.,
PROFESSOR OF LARYNGOSCOPY AND DISEASES OF THE THROAT.

LECTURE I.

GENTLEMEN: I propose commencing to-day the consideration of a subject which I know will be of more than passing interest to you. The patients that you see before you will illustrate its various phases; they will be demonstrated in a few moments. My subject is "Nasal Catarrh"—one about which much is written to-day by the profession, much more said by the laity. It is an extensive one, and I cannot hope to treat it exhaustively in the time at my disposal in this course; perhaps it is just as well that I should not attempt to do so. What you most need, as general practitioners, is condensed and reliable information concerning diagnosis, and practical advice in regard to treatment.

I have said that the subject will be of interest to you. We all hear a great deal about "chronic catarrh of the nose," and you will see a good deal of it. Patients who suffer from it, and patients who have not got it, but imagine that they have, will come to you in numbers. You certainly, then, ought to be able to recognize it when present, to exclude it when absent, and, above all, be competent to treat it scientifically and successfully. Let me ask just here, Do general practitioners always recognize it? Do they always examine for it? Are they not too apt, in too many cases, to accept the statement of the patient, make no examination, prescribe a nasal douche and some wash, and allow the patient to disappear, perhaps to excite, in time, a catarrh, where none existed before? Patients will make their own diagnosis—it is common for them to do so—and often come to you for the treatment of that which, perhaps, does not exist; often they will treat themselves, without any advice. The country is flooded with advertisements, pamphlets, and books on the subject of nasal catarrh. The field is a rich one for the quack; "sure cures" multiply rapidly; new remedies are eagerly sought for by the credulous; "catarrh snuffs" crowd the counters of every drug-store; and "nasal douches" are manufactured and sold by the thousand. The quack does not spare the feelings of the patient; he pictures the disease in its most disagreeable aspects; he dwells upon the worst symptoms; he confounds other diseases—syphilis, for instance—with simple catarrh; in short, he frightens.

Your patients, then, well posted in literature of this class, come to you, dreading that the nasal trouble that they have, or, perhaps, have not got, will develop into the worst form of catarrh that they have read about; above all, that it will develop a disagreeable odor. A symptom that they also often dwell upon, regarding it as a sign of the dread disease, is "a constant dropping of mucus in the throat"—an ever-present desire to clear it. Some little mucus they do bring away; often not. Let me warn you here that, in a good percentage of these cases, all this has nothing to do with "nasal catarrh." The patient is probably suffering from a simple, relaxed throat, or a chronic pharyngitis, in one of its forms; perhaps, and most commonly, a relaxed or elongated uvula, and that these, especially the latter, are the matters at fault, *not* the nose. All this you must prevent, they cry to their doctor; they demand treatment at your hands. Now, much of this nonsense you, as sensible medical men, can prevent. But, first, you must yourself know what "nasal catarrh" really is, what forms it appears under, and how to recognize the varieties by their intra-nasal appearances. The day has gone by when all nasal affections can be recklessly and ignorantly classed under the generic name "catarrh," and so treated. What a multitude of sins that word has covered!

The one symptom that patients most fear, and justly so, I have alluded to—the foul smell from the nose; but it is in reality a rare one; it only occurs in the fetid or atrophic form of nasal catarrh, which is by no means so common as the other varieties, and in ozæna, but ozæna has nothing to do with nasal catarrh. Do not forget this: it only occurs in patients who are the victims of syphilis or struma—patients who have syphilitic necrosis of the nasal bones, with a stinking, purulent discharge, a discharge due to the presence of dead bone. The same thing sometimes happens in scrofulous subjects. Under these circumstances, then, you may have the fetid, stinking disease, ozæna; but only under these circumstances. Do not call cases of nasal catarrh, even the fetid form, ozæna; they have pathologically nothing in common. Remember, also, that fetid or atrophic catarrh is, as I have said, unusual; and thus you are able, at once, to reassure your patient in regard to the most dreaded symptom.

I have said this much in order to prove to you the necessity of your learning to recognize the varieties of nasal catarrhal disease; for not alone diagnosis, but, what is equally important, your correct views regarding the questions of prognosis and treatment, will depend upon your acquirement of this knowledge. Some forms of nasal catarrh are curable, others are not. Is there, then, more than one form of "nasal catarrh?" Most certainly; and you will learn to differentiate them. First, acknowledge the fact that they do exist. You will meet with three varieties: 1. Simple chronic rhinitis; and let me say here that I prefer this term rhinitis to the one—"catarrh"—which is so commonly used; 2. Hypertrophic rhinitis; and 3. Atrophic or fetid rhinitis.

Simple chronic rhinitis is, as the name implies, a chronic inflammation of the nasal mucous membrane unattended by structural changes of any moment—its only symptom is an increased discharge of mucus, or, if

it has lasted some time, muco-pus—this discharge is thin and easily removable, there is no interference with the sense of smell, and no obstruction to respiration. The anterior rhinoscopic examination will show you simply congestion of the mucous membrane, the latter flecked here and there by soft, easily removable, slightly yellowish mucus. As far as the amount of free space is concerned, it is normal, there is no thickening or hypertrophy of the membrane. Posteriorly the rhinoscopic mirror will exhibit about the same appearances, except at the vault of the pharynx, where the glandular tissue is large in amount. Swelling of these glands gives a turgid aspect to the parts, and the secretion which covers them in, in part, is thicker and more tenacious—chronic pharyngitis may or may not coexist. Such patients do not, as a rule, consult you; the trouble is too slight, and unless they are morbidly sensitive or easily frightened, they allow the pathological process, through ignorance of possible results, to continue without treatment. Thus week by week, month by month, it continues, until the simple form of rhinitis develops into the second variety, which we term hypertrophic nasal catarrh, or rhinitis. We now have marked structural changes, a proliferation of all the normal elements of the mucous membrane, a true hypertrophy. The whole mucous membrane of the nasal passages, but specially that over the lower turbinated bones, is markedly thickened and relaxed; the plexus of bloodvessels, a true erectile tissue, which underlies the membrane, in the latter locality, becomes enlarged; the glands at the vault of the pharynx participate in the pathological process and likewise hypertrophy. Secretion is excessive, thick and tenacious, showing that the glandular elements of the mucous membrane have not escaped. Such a hypertrophy of tissue of course occludes more or less, perhaps permanently and completely, but more commonly intermittingly and partially, the nasal passages; the patient breathes with difficulty, his voice becomes nasal in character, he experiences much discomfort, and then decides, for the first time, to consult a physician.

Hypertrophic rhinitis, then, will be the form of catarrhal disease of the nose that you will oftenest be called upon to treat. Fortunately, you can give your patient great relief, but of this in one moment. Make now your anterior rhinoscopic inspection. You will see at once that the anterior extremity of the inferior turbinated bone on one, perhaps on both sides of the nose projects far out into the free space of the nasal passage, indeed, may lie against the nasal septum, and thus close the passage, that the mucous membrane covering it is thickened and congested, and hidden more or less by thick, muco-purulent discharge. The thickened membrane over the lower turbinated bone hangs downwards, thus encroaching upon the inferior meatus of the nose. If you touch it with a probe, it indents deeply and recovers itself slowly. The membrane covering the middle turbinated bone and the side of the septum, are affected to a less extent, perhaps not at all. Posteriorly—observe carefully the posterior extremities of both middle and inferior turbinated bones, but specially the latter. The mucous membrane is not only markedly hypertrophied, but has a peculiar rugged appearance; it is thrown into fissures and irregularities, and has a whitish appearance. A veritable tumor is thus formed, characteristic in its appearance and marked in its results, for it closes, by its bulk, more or less of the posterior nasal opening. This closure is also assisted by the thickening that will be seen in the form of an irregular, ovoid tumor upon the side of the septum. At the vault of the pharynx both mucous membrane and glandular tissue are involved, the latter to the greater extent. Thus we see an irregular, nodular tumor, traversed by seams and fissures, presenting a variety of aspects, according to the degree and kind of development, but always occupying and obliterating the normal, rounded, concave cavity of the vault. Chronic pharyngitis, frequently the follicular form, will also be present, and, occasionally, chronic laryngitis.

As a result of this process of intra-nasal hypertrophy, in certain cases following it, when it has lasted some time, or, more rarely, occurring early in the disease, before hypertrophy is far advanced, the third form of rhinitis develops. This we call atrophic or fetid nasal catarrh. I have told you that it is by no means as common as the preceding varieties. It means this: remember that in the hypertrophic form we had in the deeper layers of the tissues a deposition of newly developed connective and elastic tissue. This may cause two results—first, by its mere presence and amount, it may press upon, cause atrophy of, and destruction of function in, the glands and follicles which stud the mucous membrane. It crowds them to death, so to speak. This may occur, as I have said, early in the disease; if later, as it commonly does, the process of atrophy of the mucous membrane, and especially of the glands, has a different explanation; it is now due to the contraction that takes place in the connective and elastic tissue that has been developed in the hypertrophic form of the disease. The more and more firmly this becomes organized as time goes on, the more and more completely does it compress and destroy the function of the secreting glands and follicles, and with them the mucous membrane in which they lie, and the submucous structures, atrophy. Even more, if the process be long continued, the effect of this continued pressure, aided by the pressure of inspissated secretions or crusts, is exerted upon the turbinated bones themselves. Atrophy, interstitial absorption, is set up in them, they become smaller than normal, and the result is shown in the abnormally large, wide, roomy nasal passages, covered by a tense, dry, shining mucous membrane, often with hard crusts of mucus covering it. In these cases you can often look directly through the nasal passage back into the pharynx, so wide is it.

The symptoms that these pathological changes occasion are not as marked as in the hypertrophic form. There is plenty of room through the nose for the respiratory current to pass, hence there is no obstruction to breathing experienced by the patient. The discharge, instead of being profuse, is scanty, and dries into crusts and scales. There is no interference with the *timbré* of the voice. The only symptoms, then, are interference with the sense of smell, as a rule, the atrophic process having extended upwards to the olfactory region, and affected the terminal fibres of the olfactory nerve, and general uneasy sensations, sometimes amounting to pain, with excessive irritability and sensitiveness to atmospheric changes. The rhinoscopic appearances, both anterior and posterior, are sufficiently indicated, in my description of the disease; I will not, therefore, dwell upon them. The posterior wall of the pharynx will be

dry and shining, and without any enlargement of its follicles.

So much for the atrophic form, but I have coupled with this term the one fetid. The latter condition follows the former closely, indeed, is part of it if it has lasted any time, and I see no need, clinically, to make a distinction between the two. Fetor is the direct result of the atrophy, in this way: The secretions are scanty and tenacious, as I have told you, and become more and more so, as atrophy of successive follicles and glands takes place. The explanation of this is simple: the atrophic process has affected first and chiefly the *serous glands*, which are numerous in the nasal mucous membrane; their function is, by their secretion, to render the nasal mucus thin and watery, but this function being abolished by their destruction, the mucus secreted by the mucous glands, large numbers of which still remain intact, is viscid and tenacious; it adheres to the mucous surfaces, and rapidly desiccates in the respiratory current of air. Large crusts and scabs thus form readily and cling closely in the nasal passages and at the vault of the pharynx. Impacted in the narrowed parts of the canals, pent up beneath the turbinated bones, constantly growing in size by the addition of the secretions poured out beneath them and prevented from escaping, is it any wonder that putrefactive changes set in, that the matter thus imprisoned decomposes, that fetor is established, and not only this, but the irritation of the mucous membrane, caused by the presence of these pent-up purulent discharges, for from muco-purulent to purulent they rapidly change, reinfect the membrane, so to speak, excite further discharge, and thus constantly aggravate the disease.

So passes the atrophic form of rhinitis into the fetid—not always though, fortunately for the patients, and not very rapidly in any case. The symptom of the condition now established may be given in one word: fetor—stinking truly in every sense, disgusting to the patient, disgusting to his friends, disheartening to the physician, who must acknowledge his inability to do more than relieve his patient—cure the condition which gives rise to it he cannot. The only difference, rhinoscopically, which is perceptible between the atrophic and fetid stages of the disease is the increased amount of crusts and yellowish or greenish scabs, and, perhaps, the increased degree of space, due to the atrophy of all the parts upon which they lodge, which is seen in the latter variety.

Let me now recapitulate. We see, clinically, three forms of chronic rhinitis: 1. Simple, uncomplicated, chronic rhinitis; 2. Hypertrophic rhinitis; 3. Atrophic or fetid rhinitis. Certainly, these names and forms must be easy to remember. How important for your success in their treatment and views as to prognosis the remembrance of them and of their different pathological natures is, I have tried to impress upon you. Be sure, then, by means of the direct anterior and posterior rhinoscopic examination of the parts, that I told you, early in the course, how to make, that you know just where your patient stands in the pathological scale.

I turn, now, to a part of my subject which will have, perhaps, a more active interest for you, namely, the *treatment* of chronic rhinitis in its various forms. Here, again, I must limit my remarks. The medical journals teem with advice as to the proper methods of treatment. Everybody has something to say about the way to manage chronic catarrh of the nose. Much that you read will not commend itself to your good judgment, to put it mildly. Some advice is reliable. I shall try to remember, in what I am about to say, that I am speaking to those who are, or are about to become, general practitioners, and, therefore, will not have at their command the elaborate apparatus, the many instruments, and the varied means of treatment possessed, perhaps, by the specialist, and while I am obliged, in order to make my lecture complete, to allude to all recognized methods, surgical as well as medical, I intend to give you simple rules, by means of which any one of you can treat his cases. You will, of course, understand that I refer to uncomplicated instances of chronic rhinitis. If there coexist in given cases such complications as deflected septum, multiple hypertrophies, nasal polypi, exostoses, and cartilaginous thickenings of the septum, large hypertrophies, veritable tumors of the adenoid tissue at the vault of the pharynx, it is, perhaps, best that you should entrust them to the more skilled hands of those whose special studies and experience fit them to undertake the task.

First of all, let your patient clearly understand whether or no he really has "nasal catarrh;" you may, perhaps, give him much comfort in this way. If he has, make up your mind as to the particular form; upon this depends what you tell him, in the way of prognosis, and what you ought to do in the way of treatment; in any event, let him clearly appreciate the fact that you cannot cure his disease in as many days as he has had it months or years; perhaps, that you cannot cure it at all (in the atrophic or fetid form), but that you can give him much relief from his most urgent symptoms. Honesty is here the best policy. Inform him that he will require some patience, you some regularity in his visits (as a rule, the domestic treatment of chronic disease of the nose is unsuccessful), that there is here no royal road to success, but that, with patience and persistence, much good can be done, that success often, much oftener than is commonly believed, can be attained, and by success I mean complete, permanent, cure.

Now what are you going to do for your patient? First, you are to determine carefully whether any indications exist in the given case for general constitutional treatment, apart from local measures, and they not only often do, but are too often overlooked. If what we term a catarrhal diathesis be present, if scrofula or herpetism can be proven to exist, in short, if the nasal catarrhal disease depend upon a diathetic condition, general treatment has primary importance. Cod-liver oil, iron, and the iodides, with other remedies that will suggest themselves in particular cases, should be given for long periods. Prophylaxis, likewise, should not be forgotten; the careful attention to all habits which proceed from due consideration of wise hygienic laws will often constitute an important part of the advice that you give to your patient. Bathing, clothing, and temperature, friction and shampooing will, in many instances, be a duty upon which you will insist. The question here arises whether any of the special agents of the pharmacopœia that have been from time to time recommended as having a useful therapeutic effect upon the mucous membrane of the respiratory passages in a diseased condition are in reality of great value. I believe

that this is questionable. I have made use of many and have never been able to convince myself that any one possessed a decided specific effect. Cubebs, ammoniacum, muriate of ammonium, and perhaps sulphur, have given the best temporary and sometimes permanent results. In each case, however, their use has been associated with that of local and direct treatment of the mucous membrane. In many cases, on the other hand, the affection will appear as a purely local one, and can be met and conquered by local treatment alone. This is of unquestionable value; the means we will consider in our next lecture.

ORIGINAL ARTICLES.

SARCOMA OF SYNOVIAL SHEATHS.[1]

BY THOMAS M. MARKOE, M.D.,
OF NEW YORK.

DURING the past four years several cases of disease of the synovial sheaths in the sole of the foot have presented themselves to me, the nature of which I failed to comprehend, and the gravity of which I did not appreciate till the results, which I propose to relate in this paper, afforded the data for a correct judgment as to the nature, and some help at least towards a correct diagnosis, of the affection. The disease which I propose to describe to the Society must, I think, be a rare one, as I have seen only the three cases here recorded, and perhaps the best way of introducing the subject will be to describe the last case which has come under my notice.

CASE I.—A. B., a middle-aged man, apparently in excellent health, presented himself at my office, during the spring of 1883, for advice concerning a swelling which had slowly developed in the sole of his foot. He said that about two years previous he began to suffer aching pain in the part, which he could not attribute to any strain or bruise. This pain was principally felt when standing, or after walking too far. About eighteen months ago he first noticed a fulness in the sole, most marked under the metatarsal bone of the great toe, but extending along the sole up behind and a little distance above the internal malleolus. This extension from its original seat had taken place very slowly, and, he thought, was still going on. By reason of this swelling the foot has gradually become so disabled that he can scarcely walk at all without a crutch, and his sleep at night is much disturbed. He feels tolerably well in all other respects, but the condition of his foot completely disables him. On examination, a swelling was found occupying the inner half of the sole, and extending round the internal malleolus up a little distance above that prominence, where it terminated somewhat abruptly. The swelling was tolerably firm, but yielding to pressure in such a way as to convey the idea of a fluid or semifluid substance contained in a firm and rather tense cyst or sac. This idea was strengthened by an indistinct sense of fluctuation which could be felt at different points of the swelling and was sufficiently distinct to have induced the gentleman who had charge of the case to aspirate the tumor. No fluid was obtained. The tissues surrounding the swelling seem to be in a perfectly normal condition, and no inflammatory features have at any time been noticed. After a careful examination of the case, I pronounced a very doubtful diagnosis, and added a prognosis which I said might be very serious, including in the future a possible amputation, and—what I did not say to him, however—a possible fatal termination. My reasons for this gloomy prognosis were drawn from my experience in two previous cases, which I now propose to relate.

For the clear understanding of what I am presenting to the Society, I ought perhaps to recall a few points in the anatomy of the parts involved. It will be remembered that, as the tendons about the wrist and ankle pass under their annular ligaments, they are contained in fibrous canals, which hold them firmly in their position and afford them a fulcrum, if we may call it so, against which the tendons act, in the varying positions of flexion and extension of the hand and foot. To facilitate the play of these tendons, the fibrous sheath is lined by a serous, or rather a synovial membrane, which at varying points is reflected from the surface of the sheath on to the surface of the tendon. This arrangement produces the usual closed serous sac, through which the tendon, covered by its layer of serous membrane, plays with a freedom from friction which is much increased by the smooth lubricating synovia which is secreted from its free surface. In the ankle these synovial sheaths commence a little above the malleoli, and extend forwards into the sole to a distance varying with the point of insertion of the tendons they accompany. The one accompanying the extensors of the foot and the flexors of the toes, is, it will be remembered, rather more extensive than the rest, and passes round the internal molleolus into the sole extending quite far forward dividing into a compartment for each separate tendon as it goes toward the distal end of the metatarsal bone to be inserted into the phalanx. It is well known that these synovial sheaths are subject to certain diseases, in which the synovial secretion is increased and variously altered. These diseases give us the usual swellings along the course of the tendons with which we are all familiar; which swellings may contain either pure serum, or thicker fluids variously modified, or fluids containing semisolid particles in the shape of rice grains or melon-seed and various other modifications of concrete fibrin. All these cases present one common feature, viz., an elastic, somewhat tense swelling which gives a feeling of fluctuation which is more or less distinct according as the contents are fluid or semisolid, the walls of the sac thick or thin, and the distention of those walls great or slight. The recognition of a distended synovial sheath is a matter of no great difficulty, but the appreciation of the nature of its contents is not so easy. Aspiration will reveal this point in many cases, but in many others nothing but a free incision will suffice. These affections, as most of us have experienced, are sometimes difficult to manage, particularly those of long standing, when the walls of the sac have become very much thickened, and the contents perhaps semisolid. Operations

[1] Read before the New York Surgical Society April 9, 1884.

upon these serous sacs have always been regarded with anxiety, because of the inflammation liable to follow their incision, an inflammation which unfortunately does not always confine itself to the serous membrane, but spreading to the surrounding areolar interspaces produces some of the most formidable cases of far-spreading suppurative cellulitis.

The following cases present some features in which they differ from those which I have thus sketched, and serve, it seems to me, to suggest a modification in diagnosis, and a caution in prognosis which may possibly save a serious disappointment.

Case II.—Frank McN., æt. 43, a man of good habits, and apparently in excellent health, came into the New York Hospital December 5, 1879, with a swelling on the plantar surface of the great toe of one foot. It had commenced about two years before, without any known cause, and had slowly and steadily increased in size. It was from the first somewhat painful on walking, but of late had become so serious an impediment to him that he was very desirous that something should be done for his relief. There had never been any evidence of inflammatory action about it, though it was more painful at some times than at others, particularly when he had been obliged to stand or walk on it more than usual. On admission, a softish, doughy-feeling swelling occupied the under surface of the great toe, extending back into the ball of the toe, so that its posterior margin was well behind the metatarso-phalangeal articulation. It had an elastic feel, and when pressed upon the whole swelling became hard and tense. A feeling of fluctuation was distinct enough, but left a doubt in the mind whether it was produced by a fluid or a semi-solid material within the cyst. The cyst wall seemed to be quite thick. The diagnosis was clear as to the distention of the synovial sheath, but the nature and consistence of the contents were not so manifest. My notes do not say that aspiration was performed; but if it was, no information was elicited by it. The case was regarded as one of the usual forms of distention of the synovial sheath from a low grade of inflammation, with effusion of a fluid, which had become partially solidified by the admixture with it of some form of aplastic fibrin. I was at that time experimenting with "through drainage," and on the 6th of January I employed that method in the treatment. An opening was made into the sac as far back as possible, and the contents were, with some difficulty, squeezed out. The substance thus evacuated was of a yellowish-white color, looking not unlike the sebaceous contents of some of the cysts of the scalp; but it was evidently not a perfect fluid, for certain portions of what was squeezed out showed some such coherence as would be found in a soft growth which had been forced from the cavity in which it had lain, and which, though in the main broken up into a diffluent pulp, showed clear indications of its having been originally a continuous tissue, though of the softest possible consistence. Not much attention was given to this peculiarity at first, as its cohesion was supposed to be explained by the idea of the fibrinous masses of which the substance was partly composed adhering more or less intimately together. It was afterwards recognized that this feature was of most important significance. After emptying the cavity of all that could be forced out, the walls, as far as could be seen through the opening, presented the ordinary smooth, shining, white surface of healthy synovial membrane. An opening was now made at the anterior extremity of the cavity, and a perforated drainage-tube passed from one opening to the other. The wound was dressed antiseptically, and the ends of the tube were allowed to project through the dressing, thus allowing the cavity to be easily washed out with a weak solution of carbolic acid. No inflammatory reaction occurred. The tube was removed in about a week, and the wounds soon healed. The patient thought himself cured, and could walk pretty well before he left the hospital. Six months afterwards, I saw him, with the swelling about as bad as before, and the impairment of motion steadily increasing. From that time I have not seen him.

The report of the pathologist on the material expressed from the cavity was as follows: "Specimen consists only of irregular fragments scraped and torn out of what seemed to be a cyst, though the cyst-wall was not demonstrated. Microscopic examination: 1st. When examined in fresh state there was found to be much amorphous fibrin, and tumor was thought to be a benign cyst. 2d. The fragments when hardened show, upon section, in some cases only amorphous fibrin, but in other cases the typical structure of spindle-celled sarcoma."

Case III.—Delia D., æt. 25, entered the New York Hospital January 21, 1880, with a swelling of the sole of the foot. The history was similar to that of the other cases. She said that about two years previous she began to experience pain and soreness on walking, which she attributed to the pressure of her shoe. About eighteen months before her admission she sprained the same ankle, since which a lump appeared below the inner malleolus, which has slowly increased. It has given her much pain, especially on walking. The swelling had been punctured several times. The first time a little serum flowed out, but in subsequent punctures nothing was obtained. She appears to be in good general health, and when quiet does not suffer much from her foot. During and after walking, however, she suffers so much that she is completely disabled. The swelling occupies a large part of the sole of the foot, and extends behind and above the inner malleolus. It is softish, non-elastic, but by pressure on one part of the swelling the whole can be rendered tense. A feeling of fluctuation is perceptible, giving the idea of thick, viscid, or semisolid contents. The tissues overlying the tumor are perfectly normal. It was clearly a case of distention of the large synovial sheath which surrounds the flexors of the toes and the extensors of the foot; but the nature of the distending material could not, of course, be ascertained. In any case, opening the sac and emptying it of its contents was the first step in any method of cure. This was accordingly done January 27, 1880. An opening was made nearly as far back as the malleolus, and through it the cavity was evacuated. Nothing flowed out when the cavity was first opened, but on firm pressure a semifluid substance, which exactly resembled that found in McNair's case, was with some difficulty

forced out, leaving a large cavity extending forward so far that a straight steel sound passed quite to the root of the toes. The difficulty of extruding this substance was so great as to give me the idea of its adhesion to the walls of the sac. To make sure of this point, and to enable me to break up the semi-solid mass so that it could be thoroughly evacuated, I enlarged the opening till it admitted my finger. I could now recognized that there was, at many points, a close adhesion of the contained mass with the walls of the cavity, which were lined by a bright, shining serous membrane. The finger could now trace the division of the main cavity into several smaller chambers, which represented the prolongation of the sheath forward over each separate tendon as it went to be inserted into the phalanges. All these cavities had been enormously distended by the accumulating mass within, so that I could move my finger about through quite a large space in the middle part of the sole, and could even push the tip of it into some of the enlarged anterior digital prolongations. With the finger and with the scoop and forceps I evacuated the cavity as completely as I could, but I was sensible that a considerable portion of the mass was not reached, and could not by any of my contrivances be perfectly removed. The operation was completed by making an opening anteriorly near the base of one of the toes, and passing a through drainage-tube from one opening out at the other. The wound was dressed antiseptically, with the ends of the tube projecting, and a solution of carbolic acid 1 to 60 was injected into and through the cavity once in every three or four hours. No inflammatory reaction followed. The tube was not removed till February 6th. The wounds healed slowly. She was discharged improved May 4th, but, as in McNair's case, all traces of the tumor had not disappeared, and she could not walk without pain. The semisolid contents of the tumor were very carefully examined. To the naked eye it gave the appearance of a very soft, almost diffluent substance, much broken up by the violence done in removing it, but sufficiently coherent in many points to demonstrate that it was a soft tissue and not a thick fluid. The microscopic examination by Dr. Peabody showed "the typical formation of a spindle-celled sarcoma, being almost identical with the scrapings from the foot of McNair." She was readmitted to the hospital September 18, 1880. The swelling was as large as ever, and quite as painful. Her general condition was good. There was no cachexia and no enlarged glands could be discovered. There was, however, on the opposite side of the foot, another growth which had developed since she left the hospital, and which did not appear to have any connection with the tendons or their sheaths, and also another growth in the fatty tissue covering the lower surface of the os calcis. The clinical history, taken with the microscopic appearances, so clearly pointed to extension of sarcomatous disease, that amputation was advised and performed on the 9th of October, low down in the leg. She made a good recovery, and nothing has been heard from her since she left the hospital.

Dr. Peabody's report of the dissection of the foot is as follows: "Beneath the cicatrix, and extending thence backwards and forwards over a space irregularly circular with a diameter of an inch and a half, is a new growth. It is very soft and friable, of a reddish-gray color, and contains numerous small spots of hemorrhage. It lies beneath the skin, and spreads thence deeply downward, involving the sheaths of the tendons. On the outer side of the foot, just below the malleolus, is another mass of similar material about as large as the end of one's thumb, which bears the same relation to the superficial and deep tissues as does the growth on the opposite side of the foot. Underneath the os calcis, is a mass of the same tissue three or four times the size of the last described mass. It invades the tissue of the bone at one point to the depth of a quarter of an inch. Just behind the ankle-joint is a very small collection of material apparently similar to the others; it is not larger than the tip of one's finger. These masses of new growth are all discrete, being separated by areas of tissue to all appearance healthy. The tissue of the new growth, examined microscopically, is found to be very rich in spindle cells and in oval cells of small size, joined by a very small amount of fibrous intercellular substance." From this it is evident that the recurrence was not confined to the synovial surface, as was the original disease, but had passed through into the surrounding tissues, and besides had developed in new and isolated spots, where it was not known or suspected to exist at the time of operation. This, therefore, may fairly be regarded as a case not merely of recurrence *in loco*, but one of commencing generalization, which entitles the affection to be considered as of the most decidedly malignant character.

The literature of diseases of the synovial sheaths seems to be extremely meagre. A great many isolated cases of the ordinary forms are scattered through the journals, and Mr. Hulke, in the *Medical Times and Gazette*, gives a short account of a case in which he found, in a post-malleolar swelling, the cavity filled with small grains, as he describes them, of the shape and size of melon-seeds; but I have not yet been able to find any description of an endogenous growth within the synovial sheaths which in any way resembles that which we have been considering. Fournier and Verneuil have published short papers on the form of synovial distention which is dependent upon syphilis, but to this form their cases and remarks are strictly confined.

I have presented these cases to the Society because I think they offer a phase of sarcomatous disease which has not hitherto been described. Beside the interest which may attach to them as rare developments of sarcoma, they have, I have thought, a practical importance in the diagnosis, and especially in the prognosis of synovial diseases. Traumatic and spontaneous inflammations of the synovial sheaths, both acute and chronic, are certainly not very uncommon affections, and to discriminate between these comparatively harmless conditions and those in which dangerous and even fatal results may be, possibly, realized, is worthy of careful attention. That such discrimination can be made with certainty I would not venture to claim, but I think that the slow, painless progress—at least in the earlier stages

—the absence of distinct fluctuation, the firmness and tension of the sac, and the negative results of puncture, may lead to a suspicion, if not to a certainty, of sarcoma and may thus have an important bearing both on treatment and on prognosis.

Before concluding, I wish to read the following letter:

Dear Doctor:

I am not sure whether this case belongs to your series or not.

Male, 30, laborer. Tumor removed by Dr. Wood, June, 1869. Ten years ago patient first noticed a tumor the size of a pea in the palm of the hand. It grew slowly at first, rapidly within the last three months. It is now situated between the palmar fascia and the sheath of the tendons. It is of pyriform shape, six and a half centimetres long.

When laid open, the tumor is found to consist of a fibrous cyst-wall, from which grow soft masses filling up the cavity. These masses are soft, succulent, yellow, mottled with hemorrhages; they are composed almost entirely of cells, which are of round, oval, fusiform, and stellate shapes.

The history as to the exact position of the tumor is not satisfactory, but I believed at the time that it originated in the sheath of one of the tendons.

Yours truly,

Francis Delafield.

THE PATHOLOGY, ETIOLOGY, AND PROPHYLAXIS OF PUERPERAL FEVER, FROM THE VIENNA STANDPOINT.

By W. W. JAGGARD, M.D.,

ADJUNCT PROFESSOR OF OBSTETRICS IN THE CHICAGO MEDICAL COLLEGE.

(Concluded from p. 445.)

III. Prophylaxis: *A. Before Parturition.*—Adequate ventilation, the maximum quantity of "unprebreathed" air—to use one of Prof. Penrose's happy expressions—is the first, and, perhaps, the most important precept in the prevention of puerperal fever. In the words of Prof. Carl Braun,[1] "Puerperal women are to be isolated not by insulated houses and gardens, not by walls, but by the continuous conduction of large quantities of fresh, pure, warm air."

Since infection may occur before the first stage of labor begins, the ventilation of the apartments of the *pregnant*, as well of the parturient or puerperal woman, requires critical attention. A generous change of air is a far more efficient means of prophylaxis than the removal of articles of furniture, such as curtains and chairs, or the most elaborate germ-extermination by carbolic acid scrubbings and sprays.

The temperature of the woman should be carefully noted during the last weeks of pregnancy. Lukewarm baths, during this period, are of marked benefit. Immediately before parturition, a good bath in lukewarm water with a vigorous application of soap, is indicated for obvious reasons.

B. During Parturition.—Prophylactic measures during labor may be conveniently comprehended under the following rules:

1. The physician, midwife, or any attendant must not have come within the sphere of activity of any contagious or infectious disease for the space of twenty-four hours, at least, preceding labor. A similar degree of freedom from infectious matter is demanded as regards wound secretions, healthy or otherwise, and animal cadavers.

2. The temperature of the woman must be taken before the vaginal examination is made. If the patient has an abnormally high temperature, as the result of endometritis with or without *tympanites uteri*, the medical attendant is usually banished, after the delivery of the child, from the lying-in-chambers in the departments of Braun and Spaeth, for the space of twenty-four hours. During this period he is not permitted to examine healthy pregnant, parturient, or puerperal women. Braun enforces in his clinic, and recommends in private practice, the rule of taking the temperature of the parturient woman at intervals of three hours. He has corroborated Winckel's researches into tokothermometry, and regards the temperature as an indication of the highest importance in the determination of the time for operative procedure, and as a prognostic element during the puerperium.

3. The hands of the examiner must be free from infectious material, and must be absolutely clean. Freedom from infectious matter is assumed, if the physician's hands have not come into contact with any pus-secreting surface—healthy or otherwise—or cadaveric material, for twenty-four hours preceding labor. The second condition, according to Braun, requires that the hands, and particularly the fingernails, be scrubbed with a nail-brush in a running stream of two per cent. solution of carbolic acid; a soft soap containing a large excess of alkali is employed. After carefully trimming the nails, the hands are dipped into a one-fifth per cent. solution of potassium permanganate, until colored brown. They are then immersed for a few seconds in a ten per cent. solution of hydrochloric acid. The hydrochloric acid, suggested by Prof. Schneider, acts as an efficient disinfectant, at the same time removing the stain of the chameleon mineral. As a lubricant for the examining finger, a two per cent. solution of carbolic acid in glycerine is used.

This method of disinfection of the hands has been tried in Braun's wards, with the happiest results, since 1862. Prof. Spaeth insists merely upon Castile soap, nail-brush, two per cent. carbolic acid, and vaseline.

4. Irrigation of the external genitals during labor with some disinfectant solution, such as two per cent. solution of carbolic acid, one-fifth per cent. solution of salicylic acid, one-tenth per cent. solution of thymol, is of advantage, especially during an epidemic of puerperal fever. In protracted labors, after rupture of the bag of waters, and partial or entire escape of the amniotic liquor, sitz-baths of lukewarm water several times during the day have a beneficial effect upon parturition, and prevent infection.

5. Irrigation of the uterine cavity is indicated, after delivery of the placenta, by septic endometritis, discolored, bad-smelling amniotic liquor, dead and macerated fœtus, or by the invasion of the uterine cavity by the hand or any instrument.

[1] Gynækologie, p. 884.

The curved uterine tube is of hard rubber, 25 cm. (10 inches) in length, 3 cm. ($1\frac{1}{5}$ inch) in circumference, and terminates in an olive with lateral apertures. The irrigator is a modification of Esmarch's by Leiter, and is simply a large, conical glass flask. A weak solution of thymol is recommended as the disinfectant injection. All air in the rubber conducting-pipe and uterine tube is carefully displaced before the introduction of the latter into the cavity of the uterus. It is customary to introduce within the uterine cavity and vagina, after irrigation, a *bacillus* containing five grammes of iodoform.

6. All instruments employed during labor, inclusive of uterine tubes and catheters, are kept submerged in a five per cent. solution of carbolic acid.

7. The placenta must be critically examined, and all remaining tufts or blood-clots removed from the uterine cavity. Massage of the fundus and Credé's method of expression usually answer every indication. In Braun's clinic, in the eleven years from 1862 to 1872, inclusive, 48,249 women were delivered. The placenta was expelled by uterine massage or Credé's method in 48,132 cases, or $99\frac{8}{10}$ per cent. Detachment, by the introduction of the hand into the cavity of the uterus, was required only in 117 cases, or $\frac{2}{10}$ per cent.

In general terms, it was necessary to detach the placenta by the hand introduced into the cavity of the uterus but once in five hundred cases.

8. At the close of the third stage of labor, the perineum must be carefully examined, and all lacerations or episiotomy wounds must be closed by *serres-fines* or sutures. Contused wounds of the vagina must be painted over with neutralized tincture of the sesquichloride of iron, acetic clay, tincture of iodine, Goulard's extract, thymol, or carbolic acid. Fehling's powder (salicylic acid one part, starch five parts) acts well.

C. During the Puerperium.—The rules for the management of the puerperium may be collected under six headings, and are essentially those enunciated by Braun in a work upon the puerperal process, published years ago.

1. A rapid healing of the uterine wound is best effected by rest, restricted diet, and the most absolute cleanliness. It is seldom that vaginal injections are indicated, and still more rarely are intrauterine irrigations required.

2. The resorption of pus, secreted by the wound surface of the uterus, is best prevented by the exhibition of large quantities of lukewarm, sweetened drinks, and avoidance of all diuretics, diaphoretics, and drastic cathartics.

3. The dangers of puerperal thrombosis are lessened by securing increased uterine contraction in the third stage of labor and during the early hours of the puerperium. Massage of the abdominal walls and fundus, for a considerable length of time, at regular intervals, application of the binder, and exhibition of *secale cornutum* are preventive means which must be employed, particularly during the presence of an epidemic, even if no *post-partum* hemorrhage be perceptible.

4. The lochial secretion must be regulated by rest in bed, utmost cleanliness, protection from catching cold, and careful ventilation.

5. The resorption of pus through the genital "puerperal ulcers" must be prevented, as far as possible, by the topical application of potassium permanganate, basic sesquichloride of iron and iodoform, through the first eight days of the puerperium.

6. To check the fermentation-process in the blood, or to limit its pernicious tendencies, from five to fifteen grains of quinine may be administered daily with advantage. Dysphoria, elevation of skin temperature above 39° C., and pulse frequency above 100, constitute indications for the exhibition of this drug.

The prophylactic measures thus briefly sketched have been in active operation since 1862. The results are evident upon inspection of the statistics, which have been most conscientiously and accurately compiled, and there can be no reasonable doubt as to their absolutely truthful character.

From 1847 to 1862 there were in the Vienna Obstetric Clinic 64,500 cases of labor, with a mortality of 3.45 per cent., and, from 1863 to 1878, in Carl Braun's wards there have been 61,949 cases, with a mortality of 1.61 per cent.

Since 1878, the results have been even more favorable, so that, at the present time, the mortality rate from puerperal fever in Carl Braun's clinic is one-half of one per cent. During the winter quarter of 1883, among some nine hundred cases of labor, no death resulted from puerperal fever.

PUERPERAL ECLAMPSIA TREATED WITH PILOCARPINE.

BY E. L. MARÉCHAL, M.D.,
OF STOCKTON, ALA.

HAVING recently seen a report by Dr. Murphy, of Sunderland, Eng., of two cases of puerperal eclampsia successfully treated with pilocarpine (*Am. Journ. of Obstetrics*, December, 1883), and having, during the past year, had the same experience in the use of that remedy, in the same morbid condition, it may be of sufficient interest to the profession to justify me in putting it upon record; more especially since the unfortunate results reported by Barker, of New York, may deter others from giving their patients the benefit of what my experience, while limited, induces me to look upon as a valuable addition to our therapeutic resources.

Mrs. B., aged twenty-one years, had had two abortions at about the sixth week, and was now well advanced in the ninth month of her third pregnancy. On June 20, 1883, I was requested by her husband to see her, on account of the disturbed condition of her bowels. I found her sitting up, but enormously œdematous, and with vision so disturbed as to be unable to recognize anyone when seated beside her. There were headache, vertigo, and persistent nausea, with occasional paroxysms of vomiting. While the bowels were greatly disturbed, the calls to stool being frequent and the dejections watery, the urinary secretion was so much below

the normal as to be practically *nil*. Upon examination with heat and nitric acid, the urine became almost solid in the test-tube. No microscopic examination was made. Ordered her to have sulphate of magnesia to encourage the watery dejections, and Basham's mixture *ter die*. For the next several days there was an apparent improvement in her condition, the œdema partially subsiding, and the kidney secretion being greatly augmented. On the morning of the 24th, she was seized with eclampsia. Found her in a convulsion, having had two before my arrival. Upon inquiry, I was informed that in the past twenty-four hours there had been no action upon the bowels or bladder, and soon satisfied myself that the latter organ was empty. I immediately gave one-fifth of a grain of pilocarpine muriate, hypodermatically, and in four or five minutes the characteristic sweating ensued. She went into convulsions just as I administered the pilocarpine, but so soon as its characteristic effects were produced she became thoroughly relaxed, and had no further trouble. In five hours there was a copious dejection from the bowels and bladder. The pilocarpine produced profuse sweating, and notwithstanding that she lay in a comatose condition for the next twenty-four hours, it was not thought necessary to give anything, not even to counteract the so much dreaded depressant effect of the remedy employed. On the 26th, she was bright and cheerful, but still complaining of dimness of vision and headache. On the 27th, after a perfectly normal labor of short duration, I delivered her of a living male child, without interference or an anæsthetic.

With a clear conception of its physiological action, pilocarpine was employed in the above case, with the happiest results. Believing, as I do, that puerperal eclampsia is, in most instances, a reflex-neurosis, while the retention of excrementitious substances only renders the patient more susceptible to the eclamptic seizure, and at the same time exerts an aggravating influence, I do not believe that the administration of pilocarpine would yield the same beneficial result in every case. But, in cases in which there is a complete locking up of the secretions, and convulsions ensue, the plain and positive indication is to produce vicarious elimination, and what channel is more available than the skin, and what agent more certain and rapid in its effects than pilocarpine? It acts more rapidly than the hot baths so largely employed in Vienna, and my experience, not only in the eclamptic condition, but in other morbid states in which the production of profuse diaphoresis was indicated, justifies me in the assumption that, judiciously administered, it is as safe as many therapeutic agents daily used by practitioners, and certainly as reliable.

MEDICAL PROGRESS.

Complete Dislocation of the Astragalus Forwards.—Dr. L. McLane Tiffany reports the case of a man who slipped on an icy sidewalk, and landed with the ball of the right foot upon the edge of the curb—the heel, of course, unsupported. He fell to the ground, striking his right side, and was at once aware that his foot had received injury, and so made no attempt to use or even move the injured member. Dr. Tiffany saw the patient at his home one hour later.

The foot was fixed rigidly midway between flexion and extension, the malleoli seemed nearer the sole of the foot than normal. There was no swelling, and anatomical points were well defined. A large, hard tumor was present upon the dorsum of the foot, which by sight and touch was clearly made out to be the astragalus. The extensor tendons and skin were tightly stretched over it. The bone was dislocated directly forwards the articular surface, for the tibia was subcutaneous; the head and neck could be felt anteriorly while the lateral facets for articulation with the malleoli were plainly to be recognized. Reduction was attempted, without anæsthesia, in view of the recent occurrence of the accident, as follows: One assistant grasped the heel and anterior portion of the foot, making strong extension; another steadied the limb at the knee, while the operator stood to one side of the foot and grasped the malleoli with one hand, and with the other manipulated the astragalus back to its proper situation. He made pressure from side to side upon the dislocated bone so as to dislodge it, and then pressed directly backwards toward the joint. Extension and manipulation were commenced very gently, so as not to startle the muscles already too tense. Within less than two minutes reduction was effected. The limb, as high as the knee, was enveloped in raw cotton and put in a starch and pasteboard splint. A good deal of swelling took place, and discoloration from effused blood extended in patches as high as the knee. A large, dark discoloration appeared behind and below each ankle, the bones being of course intact. Convalescence has continued without drawback. The foot remained in the splint during fourteen days.

Seven weeks after the accident the foot is still somewhat swollen, but the patient walks with a cane.—*Maryland Med. Journ.*, March 29, 1884.

Nephrotomy for Obstructive Suppression of Urine.—Mr. Bennett May thus expresses his ideas for operative measures in obstructive suppression: In anuria from impacted calculus, urine does not ordinarily accumulate in the loin to any appreciable degree. Dilatation only takes place where the obstruction is partial in degree and of long duration. Where it is sudden and complete, no dilatation occurs, because the secretion is arrested directly the pressure is equalized; and, under these circumstances, not more than half an ounce of urine will be found in the pelvis of the kidney; though ultimately, as the experiments by Strauss have shown, the organ may become converted into a cyst. The usual seat of impaction of a calculus is near the bladder, or so far down the ureter as to be quite away from the possibility of dislodgement.

His suggestion is to establish a fistulous opening in the loin (by nephrotomy) for the escape of the urine; and if the operator be so fortunate as to light on the stone at the upper end of the ureter, so much the better prospect of obtaining a satisfactory result.

When there is pain in one loin, and the patient is seen early enough, an exploratory incision should be made on that side. The incision should be made before

symptoms of suppuration set in, as patients sometimes die of abscess caused by the irritating effect of the stone.

When should the operation be performed? A previous history of suppression, with pain on the same side, or a previous attacks of nephralgia, would point to the presence of a calculus lodged in the pelvis of the kidney or in the upper end of the ureter, and would indicate an operation for the double purpose of removing the stone and relieving the suppression; and, as the further retention of the stone must lead to destructive disorganization of the kidney, he thinks that the surgeon is justified in operating early under these circumstances. Swelling and resistance in the loin, with rigors and fever, point to suppuration, and really demand the very simple proceeding of an incision down to the kidney, though it is doubtful whether it would not now come too late.

In a first attack of suppression, and without previous nephralgia, the decision may be more difficult, because spontaneous relief is not uncommon. One such recovery, after twenty days' complete anuria, is recorded by Dr. Russell. He believes the average duration of life is from six to eight days, death usually terminating the scene rather suddenly, and without uræmic symptoms. He knows that a patient can live five whole days without a particle of renal tissue in the body, and suffer very little obvious disturbance (*British Medical Journal*, September 1, 1883). But he thinks the surgeon would be justified in operating almost at any time, for he can do very little harm, though he might receive the blame of an unavoidable death in case of failure to relieve.—*British Medical Journal*, March 8, 1884.

NEPHRECTOMY.—PROF. A. VERCELLI performed this operation, in Milan, on March 10, for carcinoma of the kidney. The patient died in five hours.—*Gazz. degli Ospitali*, March 19, 1884.

THE CURATIVE ACTION OF IODOFORM IN CARDIAC LESIONS.—PROF. BAL. TESTA has recently made a report on this subject in the *Journal di Clinica e Terapia*, Fasc. 8 and 9, 1883. Iodoform was first used in cardiac affections by Moleschott. He was induced to use it by finding that it increased the force of the heart, and produced painful palpitations when given to healthy persons.

Five cases have been reported in which this drug was successfully used; of these four were cases of mitral insufficiency with œdema and catarrhal bronchitis. It has a salutary action in organic diseases of the heart and in the functional troubles dependent upon them. It should be used with great prudence, as it causes, in toxic doses, fatty degeneration of the heart, liver, and kidneys.—*L'Union Méd.*, March 11, 1884.

THE TREATMENT OF FISTULA IN ANO.—After a review of twenty-three cases of fistula ani operated on during three years in Prof. Grube's clinic, in Charkov, DR. V. M. ZAKHAREVITCH (*Vratch*, 1882, No. 36) comes to the conclusion that, as a rule, the cutting operation must be performed. The use of the thermo-cautery must be limited only to those rare cases in which the patients are extremely exhausted, and in which even the slightest loss of blood must be avoided. The method of dividing the fistulous bridge by means of a stout silk ligature must be entirely discarded, since it is associated with prolonged reaction and suppuration. In the author's cases, the wounds made by the knife healed in eighteen days; those by the thermo-cautery, in twenty-seven; and those by the ligature, in thirty-five days.—*London Medical Record*, March, 1884.

THE PRESENCE OF FIBRIN IN THE URINE.—The presence of fibrin in the urine, says MEHU, is not rare. It would seem that whenever one finds blood in the urine, fibrine should also be found; but such is not the case; for generally the examiner finds more dissolved albuminous material, and blood-serum consequently, than would be expected from the number of red corpuscles. Apart from cases of copious hemorrhage into the bladder, fibrin is not unfrequently found in the urine. It easily remains dissolved if the urine is ammoniacal, and cannot be easily separated after slight acidulation with acetic acid, since it has remained for a certain length of time in ammoniacal urine containing bacilli.

On the other hand, in certain cases, fibrine is found when there is no trace of a blood globule, or when the amount of blood is infinitesimally small as compared with the amount of fibrin. Mehu reports two cases in which the proportion of fibrin was increased; in one the urine contained no blood; in the other there was a very small amount of blood.—*Ann. d. Mal. Gén.-Urin.*, March, 1884.

LIGATION OF THE SUBCLAVIAN ARTERY.—Dr. Giovanni Paccinini performed this operation on a boy, fourteen years of age, on January 5th, in Rome. The operation was done on account of a wound of the left axilla, which involved the artery and vein. The boy was in a satisfactory condition fifteen days afterward. —*Gazz. degli Ospitali*, January 20, 1884.

TREATMENT OF RETRO-UTERINE HÆMATOCELE.—ZWEIFEL'S method of operating is, first, to wait until the tumor is absolutely encysted. An incision is then made in the abdominal wall without touching the cyst; the hemorrhage being arrested, the vaginal wall and the blood-cyst are separated. Then an incision is made in the wall of the cyst, large enough to admit a finger, so that the cyst-wall may be seized, and the cyst is then further opened with a probe-pointed bistoury. After this, it is washed out, and a drainage-tube put in. The mortality of the different methods is, by incision, 15.3 per cent.; by puncture, 15.1 per cent.; by expectation, 18.4 per cent. The operation should never be performed until it is absolutely certain that the hæmatocele is encysted.—*Archives de Tocologie*, March, 1884.

ABSCESS OF THE KIDNEY.—J. SINGER (*Prager med. Wochens.*, No. 47, 1883) reports the case of a man, æt. 25, who, when seven years old, had a fall, from which he had hæmaturia; since that time he has had occasional pain in the region of the left kidney. After an attack of typhoid fever he began to pass blood and pus in the urine, and on examination a fluctuating tumor was found in the left hypochondrium. The tumor then began to disappear, and the man recovered. Singer thinks that the abscess must have discharged into the pelvis of the kidney.—*Centralbl. f. d. klin. Med.*, February 9, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE. . . . . $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 26, 1884.

ERGOT IN CONGESTIONS.

THERE are certain long-known drugs which have acquired within the last few decades so much wider employment by the profession than they formerly possessed that they may be looked upon as new remedies. Thus it has not been very many years since bromide of potassium was used solely as an alterative, and in doses of five or ten grains. Next to the bromides in the importance of this second growth, in medical esteem, comes ergot, a remedy which seems steadily to increase in popularity and usefulness.

In a late number of *L'Encéphale* is an article by DR. GIRMA on the use of ergotine in general paralysis, and although we are very sure that few will obtain the results his enthusiasm expects, yet he has made it clear that the fungus should be boldly exhibited in cases offering the prodromal symptoms of the affection named. The first case reported by Dr. Girma was probably one of chronic alcoholism, and the cure permanent; but in sundry instances of seemingly true paresis there were very marked benefits derived from the daily use of about ninety grains of ergotine.

Without discussing the article of Dr. Girma any further, we desire to call the attention of our readers to the value of ergot as a remedy in all forms of congestions not attended with distinct inflammatory symptoms. As is well known, the drug has the power of contracting the smaller vessels,—is, indeed, the purest vaso-motor stimulant of the pharmacopœia. It seems to be a law of therapeutics that an enfeebled part feels first a new influence entering the system, and so when a vaso-motor stimulant comes upon the scene of a congestion, the locally dilated vessels are toned up more than are those of the general system, and the diseased vessels are thereby brought nearer the condition of the normal ones.

The reputation of ergot as a remedy in pulmonic hemorrhage is established, and we are all accustomed to say that the bleeding is stopped by the contraction of the vessels. It is, however, absurd to suppose that a ruptured bloodvessel can be so contracted as to arrest the flow of blood toward the leak. Probably, what the ergot does, is to put an end to the local congestion which accompanies and, in most cases, precedes the hemorrhage; indeed, is the immediate cause of it. In spinal and cerebral congestions, neurologists have been learning more and more to rely upon ergot as being at least more efficacious than other drugs; but it is probably in pulmonic and various visceral congestions that the fungus will eventually prove most useful.

When a decided effect is required, there is no use in administering the drug in the doses habitually employed by many practitioners. A teaspoonful of the fluid extract is looked upon by many as a large dose, but is really too small to be of value. Dr. Girma gives six grammes, or about ninety-two grains, of ergotine a day, which, as near as can be estimated, is equivalent to an ounce of the fluid extract. We have for years been in the habit of giving much larger doses; an ounce and a half of the fluid extract per day may be looked upon as moderate dosing. The ravages of ergotism have been so frightful that the fear of chronic poisoning is ever before the eyes of many of the profession; but we believe such fear, so far as the therapeutic use of the drug is concerned, to be merely fright at a bogy. Ergotism has occurred only in peasantry who were fed upon bread made from infected rye. When it is remembered that in bad seasons as much as thirty or even fifty per cent. of the flour has been ergot, and, also, that the German peasant lives chiefly upon bread, it can be understood what enormous amounts of the ergot have been taken—very many ounces per day. We have given three fluidounces of the fluid extract daily for some weeks, and have never seen any other evil result than disordered digestion or sick stomach.

The great difficulty in the use of these large doses is their tendency to nauseate; and the method of administration is a very important subject for study. The new extractum ergotæ, U. S. P. 1880, which may be considered as five times the strength of the ergot itself, affords much the best preparation. It is too soft to be made into pills without an excipient, but pharmaceutists habitually use too much of the latter. Their object is to have hard, firm, non-adhesive pills. There is, however, too great an increase of bulk; moreover, a large, soft, plastic mass is much easier swallowed than a round, hard body of equal size. The tendency of such masses to cohere is readily obviated by putting an abundance of liquorice-

root or other drying powder in the box. With a little care, ten grains of the extract can be so prepared as to be readily swallowed. The introduction to the profession, of soft capsules containing ten grains of the extract, would be a useful way of exercising some of the pharmaceutical energy at present so rampant.

Even with the greatest care, the hypodermatic administration of ergotine is too apt to produce disagreeable local symptoms to warrant its employment, except in emergencies. When a continuous effect is desired, it is often very well to use, at intervals, the rectum as a door of entrance to the system. A thirty grain ergotine suppository is very readily used, but, in our experience, an attempt to administer exclusively in this way soon leads to rectal irritation.

THE MEDICAL SERVICE ON THE TRANSATLANTIC STEAMERS.

During the past few years strenuous efforts have been made in England to reform the medical service on ocean steamships. The British press has lent its strongest advocacy, the principal medical bodies have recorded an emphatic condemnation of the existing system, and the British Medical Association, with its customary activity, has both memorialized and interviewed the President of the Board of Trade.

The question is not of a doctor's grievance. The present position of a ship's surgeon is certainly unfitted for an educated gentleman, yet so few are called upon to fill it that the conditions need not become a matter of wide professional concern. The really important aspect of the matter is the grave danger to the travelling public from an uncertain, and often incompetent, medical attendance, and the want of suitable means of caring for the sick during the transatlantic passage; and, further, and even of greater moment, the easy ingress offered to zymotic invasion of this country by the defective sanitary arrangements, and the absence of an authoritative sanitary administration, on crowded emigrant steamers.

The memorial of the British Medical Association succintly enumerates these dangers, and suggests a scheme of reform against which there can be no legitimate objection. Yet because it proposes that a regularly constituted marine-medical serivice should be formed, which would be under national control, and no longer subject to the ship-owners, that powerful and united body have offered a determined resistance, which so far has prevailed.

It appears that of the medical officers entrusted by British ship-owners with the care of lives at sea, a very large proportion are entirely unsuited for the important duties assigned them. Thus, of 141 who during the first six months of 1882 had medical charge of transatlantic steamers, not less than 60 would have been ineligible, through lack of the minimum professional qualification, for the most junior medical appointment in any of the English public services; while of the entire number only 27 who had reached their thirtieth year, possessed the lowest qualification as physician and surgeon which would entitle them to seek employment in the treatment of English soldiers, sailors, convicts, or paupers. In conjunction with which we learn that the ship-surgeon has not a particle of administrative authority, even in the most purely sanitary matters; that he is a kind of puppet in the hands of the captain and owners, and dare not take any step—no matter how urgently demanded for the safety of the passengers—which would be contrary to the interests or pleasure of his employers; that the hospitals on board are insufficient, ill placed, and often devoted to other purposes than the accommodation of the sick; and that there is absolutely no provision for the nursing of the sick, no matter how large the number of passengers carried.

Then comes the disastrous result: Among emigrants to this country, who are usually of high vitality, among whom there are fewer women and young children than in any stationary population, all of whom were passed as healthy at the commencement of their ten days' voyage, and under circumstances which should be eminently favorable to health, there exists a mortality over double the ordinary death-rate on land—a mortality pronounced by those well qualified to judge to be far in excess of the necessities of transit. And when so many deaths occur during the short transatlantic passage, it is reasonable to believe that there is a general depression of health which may be a permanent injury to many, or fatal soon after landing, but of which it is impossible to form an accurate estimate.

This defective medical service on shipboard is of most importance to the public at large in its bearing upon the importation of infectious disease. Scarce one of the lesser outbreaks of smallpox or other zymotic fever, which are of such frequent occurrence throughout the United States, but can be traced to the recent advent of immigrants; showing how futile is our quarantine system under present circumstances. Medical inspection at the time of disembarkation may be, for various reasons, desirable, but it cannot detect infectious fevers in their incubation stage, and therefore is no protection when they have appeared on board during the voyage, or when that has been accomplished within the longest incubation period of disease—possibly contracted before starting. Security in this regard must therefore lie in insisting upon every vessel and her passengers remaining in absolute quarantine during at least fourteen days from possible infection, or else in providing for a thoroughly reliable and independent medical service on board.

This latter alternative will certainly be most con-

venient, and to accomplish it should engage the earnest attention of Congress when the bill introduced by General Slocum comes before the Committee. It is believed that the service can never be thoroughly satisfactory until the medical officers are removed from the control of the ship-owners, and appointed by, and held responsible to, a government authority.

Three-fourths of the passengers by transatlantic steamers are either Americans or emigrants intending to make this country their permanent place of residence. It is therefore not only the right of our Government, but its manifest duty, to at least exercise supervision over this service. The British Australian Colonies long since established a precedent for even an active control; every vessel carrying emigrants to Queensland, New Zealand, or New South Wales, is forced to have on board a medical superintendent appointed by the Government of the Colony, and responsible to it alone. Why should not the United States show equal solicitude for the protection of its citizens? Certainly it is useless for Congress to make laws regulating the carriage of passengers by sea without in some way providing for their enforcement.

PARALDEHYDE AS A HYPNOTIC.

Since the publication, in 1883, of the papers of Cervello and Morselli, upon the physiological action and therapeutical effects of paraldehyde, from which it appeared that the agent was a valuable hypnotic, producing a calm sleep, without bad after-effects, the drug has been tried by Berger, Gugl, Peretti, Langreuter, Albertoni, Quinlan, Dana, J. Brown, Dujardin-Beaumetz, J. C. Wilson, Riggi, and others, with the most promising results.

The latest contribution to the subject is that of Dr. von Noorden, of Giessen, published in the *Centralblatt für klinische Medizin*, No. 12, 1884. Given in doses varying between forty-five and ninety grains, the average being about sixty-eight grains, a refreshing, profound sleep was induced in from fifteen to forty-five minutes, which lasted from five to six hours, and was followed, in exceptional instances only, by nausea and persistent bad taste. It was found to be especially useful in the wakefulness of nervous affections, in pneumonia, emphysema. bronchitis, pulmonary phthisis, spinal and other nervous disorders, myocarditis, valvular insufficiency, icteric pruritus, chronic rheumatism of the joints, and for the relief of neuralgic and rheumatic pains. As contraindications, there were noticed serious disease of the stomach, and phthisis in an advanced stage, with implication of the larynx, in which the cough was increased, and nausea and vomiting were excited, probably as the result of direct irritation of the ulcerated mucous membrane. In only two of the other cases were vomiting and headache produced, inconveniences which, it need scarcely be said, are witnessed after the administration of other narcotics.

Particular care was taken to observe the action of large doses of paraldehyde on the respiration and the circulation. While it exerted no influence whatever on the breathing, it slightly reduced arterial tension and the frequency of the pulse; but these effects disappeared in a few hours. These observations are confirmatory of those of Peretti, and they are of great value in indicating that the remedy may be administered with safety in cases of weak heart and other cardiac affections in which chloral hydrate is contraindicated. It should be remarked, however, that in a recent discussion at the Société de Biologie, published in *Le Progrès Médical*, March 22, 1884, Hénocque and Quinquaud declared that the drug slowed the respiratory movements, without acting on the heart, and Bochefontaine, on the other hand, observed that it diminished the rapidity of the pulse.

From the observations of Von Noorden, and of those who preceded him, it is evident that we possess in paraldehyde a hypnotic which is superior to, and more generally applicable than, chloral, since it can be administered for long periods in cases in which the latter drug would prove dangerous. A larger dose is, however, required to produce sleep than of chloral, and as it is rapidly tolerated, the dose has to be progressively increased. From the standpoint of expense, this is a serious objection, particularly in hospital practice, as we are informed that paraldehyde costs about seventy-five cents an ounce in this country, as against fifteen cents for chloral. This objection will be removed when there is sufficient demand for the agent.

KOCH'S SEVENTH REPORT ON THE CHOLERA BACILLUS.

We publish elsewhere in our current issue the last of Koch's preliminary reports on the cholera bacillus. In it will be found the details of the discovery of these bacilli in the water of certain tanks in the vicinity of Calcutta, which are in reality small ponds, often located in marshy ground, surrounded by a few huts. The inhabitants make use of the water from these tanks for every domestic purpose, including drinking, bathing, and the washing of clothing, and latrines, of a very primitive design, are frequently erected on the banks and drain into the tanks. The water is, of course, under these circumstances, highly charged with foul organic matter, and totally unfit for use.

It appears that, from time to time, there have been observed localized epidemics of cholera which prevailed among the people living in the vicinity of these

water tanks, and the resident physicians had already sought to establish a relation between the drinking water and these localized epidemics.

One of these epidemics occurred while Koch's investigations were in progress, and it was found that the tank water was used in the usual manner for bathing, washing, and drinking purposes; and that the soiled clothes of cholera patients were also cleansed in the tank. Cholera bacilli were found in tolerably large numbers in the tank water during the epidemic. Now many other examinations of tank water, sewage, river water, and various specimens of dirty water, where cholera was not raging, were made with negative results. Whence Koch concludes that the localized epidemics of cholera are due to the drinking of tank water infected by cholera washings.

Koch also considers that these facts supplement those already adduced to show that cholera is the result of a special bacillus, and in a measure make up the proof which could not be obtained through experiments on animals.

Experiments were also made as to the influence of various germicides, as corrosive sublimate and carbolic acid, on the development of the cholera bacilli in culture-fluids, as well as to the behavior of the bacilli when excluded from the air, and when surrounded by carbonic acid gas, but the results are not reported.

Experiments with a view to discovering a permanent form of the cholera bacillus, corresponding to that of the indestructible spores of other bacilli, were also made, but without success.

PREVENTION OF INFECTIOUS DISEASES IN SCHOOLS.

THE Austrian Minister of Instruction, Baron Conrad, has just issued to all the school-boards of the realm, a stringent order in relation to the prevention of the spread of infectious diseases in schools, which, if rigidly enforced, will tend to reduce the amount of sickness and the death-rate from these affections. By this action one is led to infer that this important part of the supervision of the health of the school children has heretofore been neglected, and that some outbreak of disease has suggested the authoritative intervention of the Government. The action is commendable and worthy of imitation by people claiming a more enlightened school administration.

By this decree the director of a school is held responsible for the most watchful supervision of the health of the children entrusted to his care. Every pupil suffering from an infectious disease is obliged to absent himself from school until his return is assured, by competent authority, to be without detriment to the other children. Likewise, also those persons, teachers or scholars, who in anywise have been exposed to the influence of infectious diseases, are obliged to remain away from school until it is established that their return will work no harm to the pupils.

It is made obligatory upon the director of a school to report immediately to the authorities, every case of infectious disease occurring among his pupils. Should disease of a contagious nature assume an epidemic character among the children of a locality, power is given him, in conjunction with the sanitary authorities, to close a class, or even the entire school. The director of a school is also enjoined to coöperate with the local health board in promptly removing any case of contagious disease which may have occurred among the occupants of a school-building; and, should it be advisable, the school must be closed and not reopened until after a thorough disinfection has taken place. Care is enjoined in regard to the use of disinfectants, and the children are to be properly guarded from their misuse.

Scholars are not to be permitted to visit houses in which infectious diseases are known to exist; and no public funeral is to be allowed when death has resulted from such an affection. Public notice of these rules is to be given at the beginning of every term and at the outbreak of an epidemic. Children's asylums and kindergartens come under the same regulations.

The Minister of Instruction has also issued special directions upon the subject of disinfection, which comprehend the present well-known measures and practices applicable to the sick-room, buildings, open spaces, sewage, body- and bed-linen, and clothing, water, etc., to which further allusion is unnecessary.

Specific instructions, such as the foregoing, emanating from the central government, which has the authority and power to compel their observance throughout the entire empire, give promise of comprehensive and most beneficial results. An experiment on so large a scale will be watched with the deepest interest, and will exert an influence upon school administration in other countries.

EXCISION OF THE PATELLA.

MR. DODD, of Newcastle-on-Tyne, reports in the *Lancet* for March 22, 1884, an interesting example of excision of the patella for caries, in which the joint was freely opened, and recovery ensued with a movable articulation. Instead of being the first recorded case of excision of the patella, with preservation of the functions of the joint, as Mr. Dodd thinks, we may call attention to the fact that Dr. O. B. Knode, of St. Joseph, Missouri, removed the bone for necrosis, with a similar result, and that the full details of the case may be found in the *North American Medico-Chirurgical Review* for May, 1860.

SOCIETY PROCEEDINGS.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 17, 1884.

The Vice-President Horace T. Hanks, M.D., in the Chair.

Dr. Robert Abbe read a paper entitled

A STUDY OF DUPUYTREN'S CONTRACTIONS OF THE HAND.

In it, he said, he referred to those contractions of the fingers which were formerly regarded as of a tendinous nature and considered irremediable until Dupuytren demonstrated their true character. Having demonstrated the palmar fascia and its digital prolongations, Dr. Abbe went on to say that Sir Astley Cooper really first discovered that this was the tissue involved in the contractions, but this remained practically unknown until Dupuytren made his famous dissection in 1832. In the report of his clinical lectures it is stated that the skin having been removed from the whole extent of the palm of the hand and the palmar face of the fingers, the fold or puckering of this structure entirely disappeared; it was, therefore, very evident that the arrangement which presented during the disease did not depend on this cause, but was communicated to it. The dissection being continued, the Professor discovered the palmar aponeurosis extended, retracted, and diminished in length, its inferior part being divided into cords, which passed on to the sides of the affected fingers. He cut the prolongations on the sides of the fingers, and immediately the contraction ceased, the fingers returned to a state of semiflexion, and, by slight force, to complete extension. The tendons were natural, the sheaths were not open, the articulations, ligaments, synovial membranes, and bones were in their normal state.

Since then, Dr. Abbe said, a dozen similar dissections had been made, and they demonstrated also that the tendons were unaffected, the bones and joints entirely free from disease, and the seat of the trouble confined to the aponeurosis alone. He then exhibited drawings of three dissections. The first was taken from Druitt, the original specimen being in the Museum of King's College, London. It was the dissection of a contraction of the little finger, showing a contracted band of palmar fascia, stretching across like the string of a bow, and the flexor tendons lying deeply along the concavity of the curve, close to the bones. The second drawing represented a dissection preserved in the Museum of St. Bartholomew's Hospital, and the third, Goyrand's dissection, taken from Billroth's work. The description of the latter agreed very closely with that of Dupuytren, although Goyrand regarded the lateral bands extending along the phalanges not as digital prolongations of the palmar fascia, but abnormal fibrous fasciculi, which extended from the fascia to the sheaths of the flexor tendons, into which they were inserted opposite the second phalanx.

The affection, Dr. Abbe continued, was one which rarely occurred before middle life. Two years ago Dr. W. W. Keen, of Philadelphia, had published an article on the subject in which he collected all the cases at that time on record, as far as he could ascertain, one hundred and five in number, and the average age of the patients at the time the trouble commenced was forty years. It was also comparatively rare in women, the proportion of female cases being about one in twelve.

Dr. Abbe then gave a sketch of the clinical history of the disease, in which he stated that in the first stage there appeared a flattened nodular induration on the metacarpo-phalangeal articulation, the skin not being adherent to the thickened palmar fascia; in the second stage a thickened band of fascia, extending towards the finger, could be felt, and the skin became adherent, and in the third stage there was increased thickening of this band and of the fascia, while there was also formed another band leading towards the annular ligament of the wrist, and the finger or fingers were gradually drawn down towards the palm of the hand. Mr. William Adams, he said, had given the best *résumé* of the subject which had as yet appeared, and he quite agreed with this authority in his opinion that the facts relating to the anatomical conditions, as well as the clinical evidence presented in Dupuytren's finger-contraction all agreed in negativing the supposition that the tendons or sheaths of the tendons were involved in these contractions. Like the tendons, the contraction-bands had arched fibrous sheaths; in the second place, they were not always on a line with the tendons; and, in the third place, when the bands were divided, the patient was immediately able to flex the finger or fingers as strongly as before the operation. Dr. Keen's figures showed that the ring finger was affected in eighty-eight cases, and the little finger in seventy-seven, while the index and thumb were affected in only thirteen and nine cases respectively.

In connection with the contraction of the fingers there were often associated pains, not only in the seat of the trouble, but also in other parts of the body. This was well shown in several of Dr. Abbe's cases, the histories of which he now proceeded to relate in detail. The first case (which, he said, had been previously reported) came under his observation in 1881. The patient was a cloth-cutter by trade, who had been suffering from marked contraction of the little finger for seven years, and slight contraction of the ring finger for one year. Two weeks before the operation the right hand had begun to be affected also; but all trouble at once disappeared in it, and in six months the man was able to resume his occupation.

The second case was that of a German, fifty-eight years of age, and also a cloth-cutter. Both hands were affected: in the right the ring and little fingers, and in the left the ring finger alone, and he attributed the trouble to pressure on the fingers. He had been a cutter for twenty years, and fifteen years ago the left ring finger had begun to be affected. Soon afterwards contraction of the right ring finger also commenced, and after a time he began to suffer very greatly, in addition, from "lame back." Although greatly crippled, he had pursued his occupation until three years before, when he was obliged to give up all work. He suffered so intensely from pain in the back that he placed himself under the care of Dr. Seguin, who, in connection with Dr. Gilvey and Dr. Amidon, applied the actual cautery, ice-pack, and electricity, both statical and galvanic, with little or no relief; and they believed him to be suffering from organic spinal trouble. Finally, on account

of the contraction of the fingers existing in connection with the rachialgia, the patient was referred to Dr. Abbe, who had then published his first case. On the 24th of June, 1882, he performed Adams's operation, making six subcutaneous cuts in the left hand and four in the right, and applying straight splints. There immediately followed considerable amelioration of the pain in the back, and by the 4th of July, the tenth day after the operation, the improvement was so marked that he could stoop freely, and said that if his hands had not been confined in the splints he would have been able to dress himself, something of which he had been incapable for a long time. The man had subsequently been completely restored to usefulness. The case had been carefully watched for two years, and there had been no relapse of the deformity or the pain in the back; every point gained by the operation having been retained. Casts and drawings of the case were exhibited, and Dr. Abbe also presented the patient himself, who was seen to have perfect flexion and almost perfect extension of the fingers of both hands.

In the third case the patient was fifty-seven years of age, and suffered from double Dupuytren contraction. His mother had also suffered from contractions of the fingers, but had never had gout, so far as known. The right hand had been affected nine years, and he attributed the origin of the trouble to injury to the palm of the hand in ball-playing when a youth. The ring finger of the left had begun to contract three years before, and had afterwards been successfully operated on by another surgeon. The right hand had not been treated, and was found to be the seat of very marked deformity, the thumb, as well as all the fingers, being involved. Besides the deformity, there was a grave sub-inflammatory condition of the parts, with excessive tenderness; in consequence of which the patient was rendered almost helpless and suffered, in addition, from great mental depression. He was operated on in February, 1883, and twenty-five subcutaneous divisions were necessary in order to release the fingers entirely from the contracted bands of fascia holding them down. The hand was dressed antiseptically and placed, in a position of extension, in plaster-of-Paris. Severe cellulitis and œdema followed, however, and it was two weeks before the inflammatory condition set up by the operation subsided. Excellent flexion resulted, and at the end of one year and two months all that had been gained by the division of the contraction-bands was found to have been retained; while the patient had completely recovered his spirits, and his wife stated that he was now in better general condition than he had been for years.

The fourth patient was sixty years of age, and had had the trouble for fifteen years. Fifteen years ago, he had met with a slight cutaneous laceration on one of his hands, and within two months afterwards he noticed that a bunch had formed. The ring and little fingers of both hands afterwards became contracted. Early in February last, Dr. Abbe made twenty subcutaneous cuts in the palm of each hand, and applied an antiseptic dressing. For two weeks he kept up pretty full extension with splints, and during this time there was a condition of the hands somewhat resembling subacute rheumatism. This, he believed, was the result of nerve irritation incident to the operation. The patient was now presented to the Academy, at the end of nearly eleven weeks after the operation, and although very considerable gain was found to have been made (as shown by the casts and drawings taken before the operation), the cure was not as yet complete. The trouble, Dr. Abbe explained, was not in the flexing of the fingers, but in the condition of the fibrous tissues generally, the result of the disease, which it would require considerable time to overcome.

The fifth case was that of a retired physician. He was sixty-one years of age, and had never had gout or rheumatism. The trouble had begun one year ago, and the ring fingers of both hands were now contracted. No operation had as yet been performed. The sixth case occurred in a female, who had contraction of the ring finger of the left hand, and the seventh was the result of a sprain. The eighth patient was a female, sixty-five years of age, who had contraction of both hands. She suffered from burning sensations in them, but had no neuralgic pains. The ninth case, in a man fifty-two years of age, showed well-defined palmar cords and puckered skin, and was associated with marked writer's cramp. The patient refused operation. In the tenth and last case, the patient, who was sixty-one years of age, had a gouty and rheumatic family history, and suffered much from neuralgia of the palm of the hand and pain in the back.

After a careful study of these cases, Dr. Abbe said that he would suggest the following points as a working hypothesis of the causation and character of this disease:

First. A slight traumatism, which often entirely escaped notice.

Second. A spinal impression produced by this peripheral irritation.

Third. A reflex influence to the part originally affected, producing insensible hyperæmia and nutritive changes, and resulting in thickening of the palmar fascia and the formation of contracting bands.

Fourth. Through the tissue-contraction the production of a secondary series of nervous disturbances, usually of a neuralgic character.

This hypothesis, he thought, offered a more satisfactory explanation of the manipulations of the disease than the opinion that it was essentially dependent upon the gouty diathesis, as held by Mr. Adams. In connection with the etiology, he referred to the nerve theory of acute rheumatism, as advanced a number of years ago by Dr. J. K. Mitchell, of Philadelphia, who contended that rheumatism was dependent upon peripheral irritation, and he also quoted the opinion of S. Weir Mitchell and other authorities in regard to arthropathy. Some of his cases, he said, showed the most extraordinary relief from neuralgic symptoms resulting from the operation for the finger contraction, and he had little doubt that in this affection the local condition was, as a rule, responsible for trouble that had generally been regarded as of a rheumatic character. The traumatism on which he believed the disease depended was usually so slight as to be lost sight of altogether; and where the contractions occurred in those habitually using the hands in the same kind of manipulations, it might have been only at the thousandth repetition of the act that a nerve filament became affected. The symmetry of the affection had been advanced as an argument of its being a gouty or other blood-disease; but this lost its

force altogether when it was remembered how sympathetic ophthalmia was produced through the agency of the ciliary nerves. In Dr. Keen's 105 cases, the presence or absence of the gouty diathesis was mentioned in only 48; but it was stated to be present in 42 out of the 48. This was certainly a very much larger proportion of gouty cases than he had found among his own patients, and he thought that this apparent excess of such cases was probably explainable by the fact that in by far the largest majority of the remaining fifty-seven cases there was no gout, since, if it had been present, the circumstance would undoubtedly, as a rule, have been noted. In a recent communication Mr. Adams had reiterated his conviction of the gouty origin of the disease, but it was not to be forgotten that his practice was almost exclusively among the upper classes of Englishmen, in whom gout was exceedingly common. Noble Smith, on the other hand, had found that gout was the exception, rather than the rule, in connection with Dupuytren's contraction.

In the treatment, Dr. Abbe advocated the multiple subcutaneous incisions as first resorted to by Mr. Adams. He said he had one important suggestion to make, however, and that was, not to keep up too forced extension, lest active inflammation should be set up, on the old theory, *ubi irritatia ibi fluxus*. The operation, as had been previously noted, not infrequently produced a temporary condition of the hand resembling acute rheumatism. In conclusion, he alluded to the treatment of Professor Busch, of Bonn, as described by Dr. Madelüng, which consisted in the raising of a triangular skin-flap from the palm of the hand, with its base at the root of the finger, and the cutting away bit by bit of the tense fascia beneath, as the finger was being straightened; after which the flap was replaced and fixed with sutures. The finger was left free for some days after this operation, but as soon as granulations appeared, a cylinder of wood was placed in the palm for a few days, and after this the finger was extended and kept so by means of a straight splint applied to the back of the hand. This was to be removed daily, and the finger moved, and at the end of three or four weeks the hand left free. Dr. Abbe had had no personal experience with this plan of procedure, but he thought that Mr. Adams's method left nothing to be desired.

Dr. R. F. Weir said that he had had the opportunity of seeing a number of Dr. Abbe's cases, and from noting the connection of nervous symptoms with this affection he had become convinced of the correctness of his views concerning it. Traumatism, he had no doubt, was the starting-point of the whole trouble. Dr. Abbe's latest departure, in not stretching the fingers all the way back to the normal position at first, he thought a wise one, as in this way less irritation would be caused by the operation.

Dr. Alfred C. Post said that he believed he was the first American surgeon to direct attention to this subject, though of late years he had not met much with such contractions. It had often been a matter of surprise to him that before the time of Duyputren the complaint described by him should have been mistaken for contraction of the tendons, since it was noticeable that in Dupuytren's contraction it made no difference in the position of the fingers—whether the wrist or elbow was in a flexed condition or not—which would certainly not be the case if the tendons were affected. In his own operations he had employed open section with success. He had found no difficulty in extending the fingers, but a considerable period of time was required before flexion could be secured. All his cases had been of traumatic origin, and the affection generally occurred in those who were unaccustomed to manual labor, but who took up some kind of work for purposes of exercise or recreation in which the palm of the hand was exposed to unusual pressure, such as rowing, gardening, etc. There was thus a bruising of the palmar fascia, but there was, he believed, no gouty or rheumatic element in any of the cases. It was the tissues over the metacarpophalangeal articulation that were mainly affected, and in one instance he had found it necessary to divide the sheath of the tendon, although the tendon itself was not at all implicated in the trouble.

Dr. Frank H. Hamilton remarked that for a number of years he had not been called on to treat such cases. He had formerly followed Dupuytren's advice in their treatment to a certain extent, but he could hardly say that his results had been altogether satisfactory. He thought Dr. Abbe deserved great credit for the enunciation of the theory which he had advanced on this occasion, and said that for many years the idea had been in his mind that this affection might perhaps be of neurotic origin. The morbid symptoms noticed seemed to him to be due to certain lesions, in consequence of which the annular tissue of the parts underwent an atrophy analogous to the contracture of tendons. In tendons, the latter process resulted in an absolute shortening, and, according to Malgaigne, it took about a year before the contracture occurred. The process, in Dupuytren's contraction, he thought, was not of an inflammatory nature, but one of atrophy, in consequence of which the skin became adherent to the fascia beneath. This would explain why a long time must intervene before power could be regained in the part. The theory of Dr. Abbe seemed to him sound on the whole, but he had to confess that there was a little doubt in his mind whether the affection were of traumatic origin in all cases. It was a recognized fact that it almost always occurred in the little and ring fingers, and in connection with this it had been pointed out that in England it was quite frequently met with in coachmen, who used their other fingers to a great extent and kept these almost constantly at rest; so that the element of traumatism seemed removed from this class of cases. In certain instances, therefore, persistent disuse apparently resulted in this atrophic condition which he believed to belong to Dupuytren's contraction.

Dr. Lewis A. Sayre said that he had unfortunately arrived in time only to hear the very end of the paper, but as far as he was able to judge of the views of Dr. Abbe from its conclusion and the remarks of those who had taken part in its discussion, he could only give them his hearty endorsement. All the cases that he had ever met could be traced to a traumatic origin, and in every instance a certain amount of pain in the part had preceded the deformity. This pain varied in character in different cases, and in some it was rather a tingling sensation or a vague feeling of discomfort than actual pain. After it had been noticed for several months the deformity occurred. A similar explanation to that advanced by the author of the paper had seemed to him

to be the correct one; but he had never publicly expressed such views on the subject, and, like Dr. Hamilton, he thought Dr. Abbe entitled to great credit.

The treatment advised and practised by Dupuytren was not always successful, and he did not wonder that Dr. Hamilton had not been altogether pleased with it; but the plan of procedure devised by Mr. Adams was perfectly satisfactory in every way, and he had obtained the most excellent results with it. The idea of Dr. Hamilton that there was an atrophy in connection with this affection he thought a very important one, and this would explain why it was so desirable to combine systematic massage and general manipulation with the treatment. In two cases of his own he had obtained the most excellent results by these measures alone, without resorting to any operation whatever. The skilful practice of massage for half an hour twice each day, would be found of incalculable service in restoring the vitality and nutrition of the parts. Dr. Sayre also exhibited a plaster cast of one of his cases.

DR. V. P. GIBNEY stated that it had been his good fortune to see the cases in which Dr. Abbe had operated both before and at different times after the operation, and he could bear witness to the very gratifying character of the results obtained. He had had one or two cases himself, and the painful and distressing neurosis with which they were accompanied left no doubt in his mind of their neurotic origin. In club-foot also, when the fascia was very tense, he had adopted Adams's plan, with very good results.

DR. A. L. RANNEY spoke in confirmation of the extent of the palmar aponeurosis, especially as regards the thumb, as claimed by Dr. Abbe in his paper, and said that he had verified it by his own dissections. Dupuytren's contraction, he went on to say, occurred in women more frequently, he believed, than was ordinarily supposed. Thus, Dr. Keen, in a subsequent communication, had reported twelve or fifteen additional cases in females; which would bring the proportion up to about one case in five. He could not but subscribe to the neurotic origin of the affection, and said that he believed Adams and Rowe's gouty hypothesis was untenable. Dupuytren himself had reported two cases in which the disease was congenital, and as he had never yet heard of a young infant being affected with gout, these seemed to him to argue against such an origin. The question of traumatism as a cause of neurotic trouble was one of interest, and he was inclined to take somewhat the position of Dr. Hamilton in regard to it. No one to-day, he thought, doubted the neurotic origin of writer's cramp; yet this was due to spinal irritation without traumatism. He himself had suffered from the affection, and in very many cases he had found that it occurred in those who were accustomed to do only an ordinary amount of writing.

That the part of the hand supplied by the ulnar nerve was more often affected was due, he believed, not to the cause assigned by Dr. Hamilton, but to the fact that the ulnar nerve was more exposed to injury than the radial. Thus, it was exceedingly common for men particularly to lean on the elbows, and the nerve at this point was peculiarly liable to be pressed upon. As a whole, he believed Dr. Abbe's views were correct; but it might, perhaps, be well not to insist on their absolute applicability to every possible case. There was always more or less danger, in taking up a new idea, of attempting to carry it out too far. Might not compression of a terminal nerve-filament, rather than continued hyperæmia, sometimes result in the contraction in question? In some cases, again, the gouty diathesis might perhaps, be a very important element in the etiology. That the affection was often symmetrical, however, pointed, he thought, rather to its neurotic than its gouty origin. Every one was familiar with the effect produced simultaneously upon the circulation of both ears of a rabbit by pinching one of them, which effect was due to a spasm of the vaso-motor nerves. A distinct anastomosis between the two anterior columns of the spinal cord had now been established, and therefore it was not difficult to see how a compression of the ulnar nerve, for instance, in one upper extremity, should produce the same results in both.

DR. AMIDON spoke particularly of the brilliant results achieved in Dr. Abbe's second case, in which the patient suffered so long and so severely from the trouble in the back, and in which he himself, in connection with Dr. Seguin, had tried so many different measures without affording any satisfactory relief. He then went on to say that, with Dr. C. H. Knight, he had seen that day a very interesting case of contraction of both ring fingers. The patient was a man, sixty years old, who, up to the age of forty, had pursued the occupation of a waiter, but for the last twenty years had been a drayman, and constantly accustomed to handling a balehook. The contraction in the right hand was of eight years' duration, and that in the left hand of two or three years. There was also a peculiar neurotic history in the case. Within the last two weeks the patient had had two attacks of sudden failure of power in both lower extremities, but without any loss of consciousness, or true paralysis, either of motion or sensation. The first one occurred in the evening, and he was not able to stand on his legs until ten the following morning. The second attack of loss of power of standing lasted only about two hours. The coincidence of this neurotic trouble with typical Dupuytren contraction of a symmetrical character, seemed to him of considerable interest.

DR. POST remarked that the explanation of the more frequent occurrence of the affection in the little and ring fingers seemed to him to be due to the fact that the portion of the palm of the hand with which they were connected, what was known as the thenar eminence, was more exposed than the rest of the palm, to blows or pressure, as in rowing, handling tools, walking with a cane, etc.

DR. ABBE stated that it afforded him great pleasure that his paper should have elicited so interesting a discussion, and also that his views should have received the endorsement of so many of those present. It was his conviction that, scattered throughout the country, there were a great many cases of Dupuytren's contraction, in which it was believed that the tendons were actually contracted, and, therefore, that nothing could be done for their relief. After Madelüng had published the account of Busch's successful operations, crowds of such patients came flocking to Bonn, and received the benefit which surgical interference was able to afford, and which they had hitherto supposed it was impossible to obtain. After Dr. Post published his cases eight or

nine years ago, the subject had been allowed to drop to a great extent from the mind of the profession, until it was recently revived by the London surgeons and the interesting contribution of Dr. Keen, of Philadelphia, referred to in the paper. In his remarks, Dr. Post had spoken of the slow return of flexion after the operation. This was a very noticeable feature of these cases, and the reason for it was that the fibrous tissues became so hardened in this affection that it took a year or more to restore the parts to their normal condition. He could not agree with Dr. Hamilton that there was simply atrophy present, but believed that there was positive inflammation, commencing in hyperæmia and resulting in more or less hyperplasia. Dr. Sayre, he thought, had over-rated the importance of massage in this disease, even in its early stages; since, in his fourth case, upon which he operated eleven weeks ago, the patient, who had been affected with it for fifteen years, had faithfully tried this, in addition to many other measures for relief. Massage, however, he thought, was much preferable to stretching. Dr. Ranney's idea, that the ulnar nerve, which supplied the fingers most likely to be affected, was peculiarly exposed to pressure, seemed to him a very suggestive one. That the peripheral nerve filaments were sometimes involved, was probably true, but he thought that there was a real nerve lesion, and not merely a sensory impression.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, April 8, 1884.

The President, R. F. Weir, M.D., in the Chair.

LIGATION OF THE SAC IN STRANGULATED HERNIA.

Dr. J. C. Hutchison reported two cases of strangulated hernia in which he had operated recently. Both the patients were females. One hernia was femoral and the other a direct inguinal. After dividing the stricture and returning the contents of the sac, he surrounded the sac in one case with a carbolized silk ligature, and then cut it off. The first patient had recovered entirely, and the second, still under observation, was doing well; her temperature at no time having been above 99°. He made no attempt to close the ring.

Dr. T. M. Markoe then read a paper entitled

SARCOMA OF SYNOVIAL SHEATHS.

(See page 464.)

At the close of the reading of the paper, he referred to a case in which Dr. W. T. Bull had opened the knee-joint for the removal of a loose cartilage. The body was found imbedded in the edge of one of the synovial fringes, which floated into the wound as the turbid, bloody serum contained in the joint flowed out. The body was spherical or ovoidal in shape, about as large as two peas, and of a cartilaginous hardness. On section after hardening, the microscope showed the tumor to be composed of some small round cells, many spindle cells, and a large number of giant cells, marking it as a sarcoma giganto-cellulare as Virchow terms these tumors, or, as they are more familiarly known, as the myeloid sarcoma of Paget. The case seemed to Dr. Markoe to have an interesting analogy to those which he had related.

Microscopical sections, prepared by Dr. Peabody, illustrating each of the tumors described were then exhibited.

The President said that he had the good fortune to see one of the cases which Dr. Markoe had related, and shortly afterwards he had a case which he saw at his clinic at the College of Physicians and Surgeons. A young Italian girl presented herself with an obstinate broad ganglion on the dorsum of the hand near the wrist. The patient subsequently entered the New York Hospital, and was operated upon by Dr. Peters. The tumor was found to encircle the tendons. She had been seen lately by Dr. Abbe, who reported a recurrence of the growth. Microscopically the neoplasm was sarcomatous.

FRACTURE OF THE NECK OF THE FEMUR.

Dr. A. C. Post said that he had recently seen a case which illustrated the difficulty which is occasionally observed in the diagnosis of fracture of the neck of the femur. Two weeks ago a lady, about seventy-seven years of age, a well-preserved and healthy person, fell one or two steps going down stairs, and immediately afterwards was unable to walk, and complained of pain in the region of the hip, but did not send for him until the next evening. When he saw the patient she was lying upon her back, the affected limb appeared very slightly everted, but on careful measurement he could not detect any difference in the length of the two limbs. He gave a guarded diagnosis, and said that there was possibly a fracture of the neck of the femur without separation of the fragments, and advised the patient to remain quiet. He visited her several times afterwards and found her in about the same condition, except that she gradually grew more comfortable, was able to move about in the bed without much discomfort, and after the lapse of about ten days, everything going on favorably, he nearly abandoned the idea that fracture had occurred. He therefore allowed the patient a little more liberty, such as sitting in a chair, and by the aid of assistants she might move a little about the room, and she did so.

Dr. Post saw the patient this morning, found her sitting on a chair, complaining of no pain, and with his assistance and the aid of an umbrella used as a cane, she was able to walk very slowly across the room. This evening he received an urgent call to see her, with the statement that she had suddenly become very much worse, was suffering severe pain, and when he reached the case he found that there was more marked version of the foot, and that there was shortening of the limb to the extent of about seven-eighths of an inch. The account given was that while sitting up some friend called, and suggested that she raise her foot and place it in another chair, which she did, and was not conscious of having injured the limb, but when she attempted to return to the bed, she immediately began to suffer from severe pain, and Dr. Post found the condition described, which did not exist at his morning visit. He then reached the conclusion that it was originally a case of fracture of the neck of the femur without separation of the fragments; that the fragments were held together by the thick periosteum of the neck, and probably the movement made when she raised her foot and placed it in another chair separated the fragments and allowed them to pass by each other.

He also recalled a case which occurred many years ago in the old New York Hospital. The patient was brought in after having received an injury, and he was unable to make out any shortening of the limb, although there was some eversion and a good deal of lameness. He gave the patient the benefit of the doubt concerning fracture, and did not make any extension or special manipulation for the purpose of diagnosis. It was near the end of his term of service, and he was followed by one of his colleagues, who, when he came on duty, was anxious to have a clear diagnosis, and therefore proceeded to make some extension and further manipulation of the limb, and subsequently there was no doubt whatever concerning the nature of the injury.

Dr. Post had been in the habit of treating such cases as cases of fracture until the diagnosis became clear, or until the patient got well. He thought that the case reported suggested the great importance of caution in that respect, and of being contented with uncertain diagnosis rather than subject the patient to the danger of separation of the fragments, which cannot afterward be brought together.

THE PRESIDENT remarked that Dr. Post's case of fracture of the femur was very interesting and practical in several particulars, especially with reference to the difficulty in making a diagnosis, which, in more than one instance, he had himself experienced. He thought that where the patient is thin, and Bryant's line can be made out distinctly, and there is, also, a relaxation of the fascia lata, sometimes a diagnosis can be made clear in this manner; but he had to confess that, practically, the rule laid down by Dr. Post must be followed, and that the case should be regarded as one of fracture until such a period had elapsed as would show unquestionably that only a contusion of the muscles had existed. Attempts to elicit crepitus should be made with great caution.

DR. L. A. STIMSON thought that the need of caution might be formulated even more strongly, and it might be said that when an elderly patient has fallen and struck upon the hip, with consequent inability to use the limb, unless absence of fracture can be positively made out, a diagnosis of fracture should be made; and the absence of fracture can only be asserted when all its minor indications are absent; as Prof. Bigelow has pointed out, when no eversion can be recognized, there may be diminished inversion. Another sign, recently pointed out by a French surgeon, Hennequin, which Dr. Stimson had never failed to find in any case of fracture at the hip-joint since he had learned to look for it, was a lack of depressibility of Scarpa's space—that is, the fingers can be pressed into that space less deeply than normal, and the manipulation is always accompanied by pain in cases of fracture.

A case came under his observation a few days ago, in which there was no eversion, no shortening, but there was inability to use the limb. There was a fulness of Scarpa's space, and he was able, by gently flexing the limb to a right angle with the pelvis, and pressing on the trochanter, to get a single click of crepitus, which made the diagnosis complete. He had been unable to get the crepitating click with the limb in an extended position.

Dr. Stimson asked the President if he had noticed the lack of depressibility of Scarpa's space.

THE PRESIDENT replied that he had tried it in only two cases, and it was present in each instance, but that he did not rely upon it as a pathognomonic system.

He also supplemented the case by proposing an inquiry with regard to the treatment of impaction with extreme eversion. He had seen two cases in which the eversion was so marked in subjects under fifty years of age, that he was strongly tempted to break it up, so as to get a better position for the limb; but he did not dare to do so, and the result apparently justified him in his decision, because the patients subsequently walked fairly well—much better than he expected they ever would.

DR. J. C. HUTCHISON said that in his own case, an impacted fracture of the femoral neck, there was at first great doubt whether or not fracture had occurred. He was carefully measured by three competent surgeons, one of very large experience, who made out three-fourths of an inch shortening; one of the others found some shortening; the third examined in the presence of the other surgeons, and also alone several times, and was unable to make out any shortening. Dr. Hutchison had the conviction that he had an impacted fracture, but he was not satisfied that a fracture had occurred until six or seven hours after the receipt of his injury, when symptoms developed which convinced him that a fracture had occurred, namely, spasmodic contraction of the muscles about the hip, when he fell asleep, which continued from time to time for a week. He was disposed to regard the presence of muscular spasm about the hip-joint, after severe injury of that part, as pathognomonic of fracture, but fracture here often exists when this symptom is absent. On the following day two of the three gentlemen had no doubt concerning the existence of a fracture. The fragments did not separate although he was removed from Lake George to his home soon after the injury. Dr. Hutchison agreed with the opinion expressed by other members, that when the diagnosis was doubtful in injuries about the hip, the case should be treated as one of fracture.

INTESTINAL OBSTRUCTION.

DR. POST related a case of intestinal obstruction to which he was called on the twelfth of March. The patient was a previously healthy man, thirty years of age, and when Dr. Post first saw him the abdomen was very much distended, with tympanitic percussion noted everywhere except over the ascending colon, where there was a moderate degree of dulness without marked hardness upon palpation. The patient had had no movement of the bowels for four days. There was a moderate amount of fever with considerable tenderness, and the pain was quite acute. He directed an enema prepared by infusing two ounces each of senna and Glauber's salt with half an ounce of cardamom seeds in a quart of boiling water, and ordered that one-half of the enema be administered, to be followed by an opiate. On the following morning he found that the patient had had an imperfect evacuation following the enema, and Dr. Post directed that the other half of the infusion be given, which brought away some solid matter with the liquid. Partial relief was afforded, but there was evidently a large accumulation of gas in the intestine, and he therefore directed, on the following day, that half an ounce of oil of turpentine and one drop of Croton oil,

added to a pint of flaxseed tea, be used as an injection, and it gave the patient complete relief, producing several copious evacuations, and the swelling of the abdomen subsided. The patient improved so steadily that on the eighteenth of March he discontinued his visits.

Six days afterwards, the patient's wife called, saying that her husband was suffering again, and that a hard swelling appeared the day after Dr. Post discontinued his visits, which had continued, and that his bowels had not been freely moved. Dr. Post found that there evidently was a phlegmon forming in the region of the cæcum. A swelling existed there larger than his fist, and there was dulness on percussion. Although there was no distinct fluctuation, it was evident that the tumor was tending toward the formation of pus. He concluded to perform the explorative operation of Dr. Willard Parker, and, on the 25th of March, he made an incision, separating layer after layer, until he reached the immediate vicinity of the hardened mass; and, not detecting fluctuation, he made an antiseptic application—bichloride solution, eight grains to a pint—over the wound, and from that time the patient began to experience relief. In the course of two or three days, there was a moderate discharge of pus from the wound, and the hardness subsided. The patient is now in a very good condition, and in a fair way to recovery. The discharge had been carefully inspected, but no foreign body had been found.

It was on the sixth day after hardness had been observed that Dr. Post made the incision, and he anticipated, he thought, somewhat the actual formation of matter which readily found its way into the artificial opening. He regarded it as safer to proceed in this manner, rather than to take the chances of an abscess opening into the peritoneal cavity.

The President remarked, with reference to Dr. Post's case of perityphlitis, that he had recently seen a case occurring in a young person, twenty-two or twenty-three years of age, in which the especially interesting features were the presence of normal temperature and resonance on percussion over the tumor. At first there was some fever, with constipation of the bowels and severe abdominal pain; but these symptoms soon disappeared, and after the temperature fell to the normal, the tumor first showed itself, and when he saw the case yesterday in consultation, the pulse was eighty-four, the temperature was normal, the tumor was in the right iliac fossa, but extending well up towards the median line, and was resonant on percussion. He had once seen a similar case under the care of the late Dr. Gurdon Buck, and the explanation which Dr. Buck gave with reference to resonance on percussion was the presence of gas in the cavity of the abscess.

In the present case the diagnosis was made sure by thrusting in a hypodermic syringe, which withdrew pus, and afterwards an incision was made in the line of puncture, and gas and pus abundantly evacuated. No foreign body was found in the cavity. The discharge was exceedingly offensive, although the pus had a good color.

Dr. C. K. Briddon had seen two or three cases of perityphlitic abscess in which there was resonance over the tumor, and the gas which escaped was also very offensive in character. He had also seen a case of iliac abscess as described by Dr. Buck, which was filled with gas, and for the relief of which he performed the operation devised by Dr. Buck, namely, to operate below Poupart's ligament, extending the incision down to the tendons of the psoas and iliacus muscles, opening the fascia over these tendons, and passing the finger up underneath the fascia into the iliac fossa. In this instance he passed his index finger to its entire length without getting any response, he then took a female catheter and introduced it to nearly its entire length when there came a full puff of offensive gas, and he had the impression that he had punctured the intestine, but it was not so, for the puff was quickly followed by a large discharge of pus. The patient recovered. He eventually died, however, of tuberculosis.

Dr. Post referred to a case of intestinal obstruction due to impaction of feces in the rectum, occurring in a woman eighty-five years of age. She had gone repeatedly to the water-closet, and had passed small quantities of mucus. On digital examination the rectum was found to be filled with a solid mass of fecal matter. Portions of this were removed with the handle of a spoon, and this was followed by a warm water enema which gave complete relief.

Dr. Post also referred to a case of constipation in a lady who had given birth to a child twelve days before. She had had frequent liquid evacuations, and her attending physician had regarded it as a case of diarrhœa, for which he had prescribed opiates. When Dr. Post was called, he made a digital examination and found scybala in the rectum. The patient was relieved by an active cathartic.

The Society then proceeded to the transaction of miscellaneous business.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

Eighty-sixth Annual Meeting, held in Baltimore, April 22, 23, 24, and 25, 1884.

(Specially reported for The Medical News.)

Tuesday, April 22, First Day.

The Faculty convened shortly after 12 M. in Hopkins Hall of the Johns Hopkins University, The President, Richard McSherry, M.D., in the Chair.

After the transaction of some routine business, Dr. McSherry delivered

the president's address.

He commenced by referring to the time-honored custom that required him to give an address at the opening of the convention, and proceeded to speak of the many changes that had come about in the Faculty, not only since its foundation, but since he became a member, thirty-three years ago. Amid all other changes one change has been constant, "The shears of Atropos have been busy clipping the life-threads of our fathers and brothers." We are never allowed to forget the fact so forcibly expressed by the Latin poet:

"Debemus morti nos nostraque."

Speaking of the progress of medical science, the President said that while keeping pace with all true progress, we should at the same time "keep in perpetual use a sort of mental winnowing machine, to separate

the wheat from the chaff so abundantly placed before us." Neither personal observation alone, nor scientific research alone, should be trusted to, but the utmost use should be made of both, ignoring neither the wisdom of the past nor the discoveries of to-day. The President expressed himself strongly in favor of the Code of Ethics of the American Medical Association, and hoped that the profession of the State would continue as united as they have been on this subject. Code or no code, how can a scientific physician consult with one with whose system he has nothing in common? We may use all agencies for the cure of disease, but bind ourselves to no narrow system. Politics and medicine do not blend well together, but on matters of sanitation the physician should use his influence—such as public health, drainage, quarantine, etc. The President also spoke of the need of protecting physicians in regard to testifying in court where professional confidence is involved. The address closed with remarks on the need of enlarged accommodations for the growing library.

THE REPORT OF THE TREASURER

was then read. Dr. Judson Gilman, who had for many years acted as Treasurer to the Faculty, had died during the past year, and the report was made by the Treasurer elected by the Executive Committee to fill his place, viz., Dr. W. F. A. Kemp. The report showed that notwithstanding the increased expenses this year, caused by the publication of the volume containing the *Medical Annals of Baltimore*, the financial condition of the Faculty was good and the indebtedness small—$1340.60 in all having been collected during the year.

DR. B. B. BROWNE, Chairman, read the

REPORT OF THE LIBRARY COMMITTEE.

After reviewing the work of the last ten years, it stated that since the last report, 673 volumes have been added by purchase, donation, and exchange.

THE COMMITTEE ON MEMOIRS,

DR. EUGENE F. CORDELL, Chairman, reported the death of two members of the Faculty since last year: Dr. Judson Gilman, aged 65, and Dr. E. Gover Cox, aged 63. DR. GILMAN was for more than thirty years a member of the Faculty, and has acted as its Treasurer since 1870. His wise and discreet financial management was much valued. He rendered efficient service during the epidemic of yellow fever in Norfolk, in 1855, and visited that city as a Commissioner of the Board of Health of Baltimore, to investigate the origin and nature of the disease. DR. E. GOVER COX removed to Baltimore in 1852, and continued to reside there until his last illness. He paid special attention to the treatment of diseases of women, in which he acquired great skill and success. He took an active interest in the working of various beneficial organizations, and was especially prominent in the Order of Odd Fellows.

DR. G. LANE TANEYHILL, Chairman, read the

REPORT OF THE PUBLICATION COMMITTEE.

The report showed that, in addition to the publication of the usual volume of *Transactions*, the committee had published, according to the direction of the Faculty, the *Medical Annals of Baltimore*, which had been prepared with great labor by Dr. John R. Quinan.

DR. J. E. MICHAEL, Chairman of the Section of Surgery, read

THE REPORT ON SURGERY.

He first took up the subject of *Antiseptic Surgery*. If the latter part of the nineteenth century will be celebrated in the future annals of surgery, it will be for the triumph of antiseptics and of the germ theory of wound diseases. Many of us can remember how leading surgeons used to laugh at the antiseptic plan introduced by Lister. Now it is not a question whether antiseptics shall or shall not be used, so much as *what* antiseptic. Even the opponents of the system, who believe in "cleanliness in surgery," act on the germ theory when they cleanse their apartments with chlorine gas, and boil the water they will use for irrigation, etc., before they use it, and take other precautions of the same kind. Their success is really an argument in favor of Listerism. This term should not be confined to a special formula used by Lister, for he is really the father of all antiseptic surgery. The fact that the best germicides known are also hurtful to the human organism, and the ambition of surgeons to be the introducers of new antiseptics has resulted in many experiments in this direction, and has added much to our knowledge. A perfectly certain, and yet safe, antiseptic is still wanting. Carbolic acid is dangerous. Thymol, salicylic acid, boracic acid, even iodoform and subnitrate of bismuth have been found not to be free from objection, and corrosive sublimate, although no ill results have yet been reported, is too violent a poison not to produce at some time dangerous symptoms in those who are specially open to the effects of this salt. How to use antiseptics, is a question that must largely be answered by each surgeon for himself. The costly apparatus used by Lister would be unsuitable for country practitioners; but it is not necessary, as Lister himself has shown. A good plan is to sponge or irrigate with carbolic or corrosive sublimate solution, and dress the wound with oakum or absorbent cotton and iodoform.

The report proceeded to consider *abdominal surgery*, and noted the great advances that had been made in this direction. Turning to *cancer of the breast*, Dr. Michael said that as the view that cancer began as a local disorder gained ground, operative procedures were more frequent. The enlargement of the axillary glands is not a contraindication for operating, but they should be removed as well as the cancerous growth in the breast. Even when the disease has advanced too far to hope for a radical cure, extirpation affords relief. He said that he has now two cases on hand, in one of which he has operated three times in four years, and in the other three times in three years. In the meantime, between the operations, the patients are comfortable and attend to their family duties, and so convinced are they of the advantage of removing the diseased tissues that they return of their own accord to the Hospital as soon as the disease has made itself manifest again.

He then referred to Lister's method of *wiring the fractured patella*, and expressed the opinion that while in old cases, in which the function of the limb was interferred with, this operation promised well for restoring the function, yet in recent cases the old plan succeeds, especially if the knee be kept straight for a sufficient

length of time. Bony union is rare, but restoration of function is common.

Digital examination of the bladder, as recommended by Sir Henry Thompson, was adverted to, and the reporter then went on to speak of the treatment of *strictures of the urethra*. Passing over, in a few words, the treatment of strictures of the pendulous portion, he proceeded to those of the bulbo-membranous and membranous portion. Electrolysis is highly praised, but has not yet been thoroughly proved. The treatment by perineal section, with or without a guide, in old and obstinate cases, especially where patients show that peculiar tendency to chills after manipulation, has much to recommend it, though it is often difficult and tedious. Dr. Michael considers it far safer than the internal operations. He reported a case on which he had operated without a guide in last January. The patient had severe chills after manipulation, and had become very weak and seemed on the verge of the grave. Now he is going about, constantly improving; the perineal wound is nearly healed. He passes a good stream of water, and uses a No. 16 E. steel sound.

The Chairman of the Section on Practice being absent, the reading of his report was postponed, and Dr. Robert W. Johnson read a supplementary report on

CRYPTORCHIDISM,

in which he entered very minutely into the history of the subject, and spoke of the effect this condition may have upon the mind of the unfortunate man—referring to the case of Sir Astley Cooper's apprentice, who was so depressed that he finally committed suicide. There are several varieties of perverted development and abnormal position of the testicle: 1. There may be supernumerary testicles, with which we have nothing to do. 2. We have the class of monorchids or persons having only one testicle in the scrotum, the other in the abdomen, inguinal canal or perineum, or thigh. One healthy testicle is sufficient for purposes of reproduction. 3. More rare are the cryptorchids: no testicle in scrotum on either side. These are further divided (*a*) into those who are actually devoid of testicles, or anorchids; (*b*) those whose testicles are both in the abdominal cavity or inguinal canals; and (*c*) those who are a mixture of the other classes, *i. e.*, have one testicle in the abdomen and one in the canal. Marshall states that monorchids occur once in eight hundred examinations, and cryptorchids once in twelve thousand. The individuals thus affected are apt to be effeminate, with shrill voice, beardless, or having only down upon their faces: in short, approaching hermaphroditism. This is not always the case; there may be no apparent difference between the person so affected and an ordinary man. The most singular thing of all is that there have been cases in which the wives have never suspected anything to be wrong; in fact, some of this class are extremely lascivious.

Dr. Johnson then proceeded to discuss the causes of this abnormality and the effect on the retained testicle, and concluded by saying that, as a general rule, the testicle was apt to suffer less if retained in the abdomen than if in the inguinal canal. In the latter position it is much more exposed to pressure from various causes, often from an ill-fitting truss, and it appears that malignant disease often attacks the testicle in this position. Subjectively, the influence is greater if the testicles are in the abdomen, as it affords comfort and reassurance to the man when he finds his scrotum empty to feel the missing testicle in the groin. Are cryptorchids sterile? We must distinguish between sterility and impotence; the former implies inability to beget offspring, the latter inability to have sexual intercourse. They are certainly not impotent, but are apt to be sterile, though not necessarily so. The testicle in its abnormal seat can be affected with all the ills that affect the testicle in its normal seat—orchitis, etc.

Dr. Johnson had prepared elaborate tables, of which the following is a summary:

Total number of cases,	89
Cases over 14 years of age,	66
No testicle found post-mortem,	9
Both testicles *may* have been retained in abdomen,	Uncertain.
Both testicles in inguinal canal,	18
Only one testicle in canal,	8
Seminal fluid examined microscopically,	15
Spermatozoa were found in semen (one very dubious),	3
Number having children,	10
In one case heredity was remarked where a monorchid begat a cryptorchid child.	

Dr. Johnson then related a case of his own, which he brought before the Faculty. A young man thirty-three years of age, well developed, hairy, muscular, with deep voice and full chest. He was a perfect Lothario, and quite gloried in his amours; was once in trouble on the charge of bastardy from which he escaped on the payment of a large sum of money. He claims to have had children. His mother noticed that his scrotum was empty in infancy. He is a sailor, and one day, while pulling a rope, felt something give way on his right side, which proved to be the beginning of a hernia, for which he sought treatment. The scrotum was found to be quite empty on both sides, excepting a small part of the bowel that could be felt protruding from the canal. On the first examination Dr. Johnson was able to feel the testicles presenting, but had not been able to feel them since. He examined the seminal fluid, found it lighter colored and more transparent than normal, lacking the usual smell and devoid of spermatozoa, when examined microscopically. He had repeated the examination on several occasions, and always with the same result.

As regards treatment, he said that if the testicle is retained in the abdomen, nothing can be done except to wait for its descent, which may be hoped for up to the end of the first year. If it is in the canal, moderate and gentle traction is beneficial. The traction should be frequently repeated, rather than for a long time on any one occasion. If traction is of no avail, return it into the abdominal cavity. If this cannot be done, protect it with a horse-shoe pad, and relieve the strain on the gland with an abdominal support. Keep the patient in ignorance, if possible, of his sterility.

The Chairman of the Section on Obstetrics and Gynecology being absent, his report was postponed to a future meeting, and Dr. W. A. B. Sellman read, as a supplementary report, a paper on

THE EFFICACY OF IODOFORM IN PREVENTING UTERINE COLIC AND PELVIC INFLAMMATION FOLLOWING THE INTRAUTERINE APPLICATION OF NITRATE OF SILVER.

The paper was a practical one, and gave in detail Dr. Sellman's experience with these agents. He began by saying that, in the majority of cases of endometritis, applications of nitrate of silver (gr. lxxx ad f℥j) had been the most useful agent he had used. Perfect cure or great relief followed its repeated use, and he had never seen stricture or closure of the uterine canal follow. But a serious objection to it is that not unfrequently his patients would suffer severe attacks of uterine colic either immediately after the application or within an hour, and he had seen pelvic peritonitis and ovaritis brought on by it. He then recounted a case of this kind. To relieve the colic, which was of common occurrence, he tried belladonna, opium, and hyoscyamus, without effect. Knowing the anæsthetic power of iodoform, he tried that, and has never since had any after-trouble from the application of nitrate of silver. As to the cause of the uterine colic, he said that in congestive and inflammatory conditions of the uterus there exists, as a rule, a state of hyperæsthesia, and a nervous condition of the whole organism. The application causes the cervical canal to contract, and prevents the excess of fluid from discharging into the vagina. He never had a case of uterine colic with dilated canal. Pelvic inflammation following the applications he thought due to the excess of fluid being forced into a patent Fallopian tube. He never had a fatal case, but they caused much solicitude. His method is to make the application of the nitrate of silver solution on a cotton-wrapped applicator, immediately following it with powdered iodoform applied in the same manner. Sometimes the cervical canal contracts so suddenly and violently as to prevent the applicator being passed the second time. Under such circumstances he inserts a suppository or uterine bougie medicated or charged with iodoform. He covers the cervix thoroughly with iodoform, and sometimes saturates a pledget of cotton with iodoform and vaseline, leaving a string attached for the patient to remove it the next morning. These procedures have prevented all unpleasant after-effects.

WEDNESDAY, APRIL 13, SECOND DAY.

After the routine business had been transacted, DR. A. B. ARNOLD, Chairman of the Section on Practice, read a report entitled

REFLECTIONS ON PRACTICE,

in which he passed in review the changes in the theory and practice of therapeutics which have taken place during the last half century. There have been two schools of thought in medicine, the one holding that rational therapeutics must strictly conform to scientific principles, the other that experience is the only safe guide. After passing in rapid review the work of those who prepared the way for the most brilliant epoch of medicine, the report spoke of Louis and his numerical system, which he hoped would place therapeutics upon a solid basis. This method is an empiricism pure and simple. The choice of remedies is to be decided by statistics. Admitting all that can be said in its favor, the individual peculiarities of each patient, and the varying conditions of each case, modify the indications for treatment too much to allow the entire acceptance of this theory; still, this method is the most reliable means of discovering the relative value of a remedy in a well-defined symptom — as the use of bromides in convulsive affections.

Both the French and Vienna schools have been singularly sterile in the direction of therapeutics. Rokitanski (1846) declaimed against the pretensions of founding a system of therapeutics on any other ground than pathological doctrines, and Skoda avowed the same views even more decidedly. These leaders had a great effect in unsettling the minds of the younger men of the profession in Germany in regard to the trustworthiness of the current methods of treatment. The promise of rational therapeutics, which should be the outcome of a thorough knowledge of pathological anatomy and chemistry, has not been fulfilled, and at present it appears to be chimerical. The teachings of this school, however, have had the effect of causing the practice of indiscriminate venesection to fall into disgrace. The radical fault in the French and Vienna schools has been to consider disease to be a physiologico-chemical entity against which remedies are to be exclusively directed. In fact, however, we have to treat not diseases merely, but diseased individuals with all their personal peculiarities.

The characteristic of English practice is to trust more to experience than to theory, and though of the two this may be safer, glaring fallacies have passed current on the authority of experience, *e. g.*, venesection. The difficulty in this direction is that the tendency of certain diseases toward recovery is overlooked, and must always form a difficulty in accurately estimating the curative powers of a remedy.

Modern standard works consider therapeutics a branch of physiological science, and the most certain advances in therapeutical knowledge are looked for from the physiological method. The paper closed with the consideration of the modern treatment of fevers as a good test and example of what has been gained in therapeutics.

WILLIAM PEPPER, M.D., of the University of Pennsylvania, then delivered the *Annual Address*, taking for his subject

SOME PRACTICAL REMARKS ON DIETETICS IN DISEASE.

Remembering the thoughtful little work, *Health, and How To Promote It*, recently published by the President, Professor McSherry, Dr. Pepper said he was led to hope that some practical remarks upon the subject of *dietetics* might not be without interest. On reviewing what he had prepared, however, he felt that the title selected was somewhat inappropriate, as he had dwelt more upon the relations of dietetic errors to the production of disease than upon the actual value of diet during the disease. Although the subject has not always claimed the attention which it merits, yet, on the whole, we must acknowledge that amidst the currents and counter-currents of medical opinion during the past decade there has been a constantly growing appreciation of the value of dietetics; indeed, we may safely assert that it is becoming recognized that in very many conditions of impaired health and actual disease successful treatment depends chiefly or exclusively upon proper diet and

regimen. He believed that from a proper study of the wide range and varied character of the morbid symptoms resulting from the gift of food abused, and the wonderful remedial effects of special forms of diet, it would appear that it is in this line more than in any other that the greatest triumphs of therapeutics are to be won in the near future. In estimating the influence of the factors of our physical life upon the development of the individual or race, too much importance has been attached to climate and far too little to diet and personal hygiene. For the establishment of the laws of dietetics and hygiene we are concerned only with the average man, not with those exceptional individuals in every community who display the highest physical and intellectual health whilst pursuing courses of life admissibly injurious.

In India and Australia we have seen the experiment of subjecting large numbers of Anglo-Saxons to climatic conditions diametrically opposite to those familiar to that race, and the result seems to be that with suitable diet and regimen its characteristic health and energy will not be impaired. In this country a more complicated experiment is being tried. A nation recruited from all quarters of the globe, a vast territory—wide varieties of soil and climate—the gift of freedom, personal, political, and pecuniary, to be borne by millions heretofore comparative strangers to these blessings. Can we wonder that during the fierce contest to be waged with strange and untried climatic, industrial, and social conditions many curious effects, physical as well as social, have been developed? The so-called typical American, with his pale, sallow face and tall, slender figure, full of the irritable restlessness bred of nervous dyspepsia, certainly differs widely from his English, Irish, or German ancestors, and the interesting question arises whether his physical peculiarities are inseparably dependent upon our climatic conditions, or upon other and transient influences. Prof. Pepper stated his deliberate conclusion that it is to the latter conditions almost exclusively that we are to attribute these results. He indicated the abuses of various articles of food and drink which are the undoubted cause of this state of things, and reiterated his opinion that this was the cause of most of the physical peculiarities commonly assigned to the American climate. He believed that with due regard to the conditions, there is no more favorable climate upon earth than our own. He deprecated, too, the excessive share which has been attributed to overwork in the production of many forms of nervous exhaustion. In his own experience, cases really induced by this cause were rare, and in the vast majority an amount of work entirely consistent with long-maintained health is rendered destructive by reckless disregard of the laws of health. It is true that the conditions of our higher forms of work in America are more difficult than in older and better organized communities, but a study of the habits of professional and business men in other countries has convinced him that the important question is really "How to live while working."

If it were possible for all to appreciate correctly their physical condition and capacity at the outset, so as to adapt their method of work to their physical requirements, we should see quite as much or more work done with infinitely fewer instances of (physical) disaster. The velocity and range of a projectile vary directly as the initial power, and inversely as the mass to be moved. In its application to the human body this is a most pregnant truth. To adjust the actual weight of the body to the physical powers of the individual, and to render these innumerable minute processes as easy and complete as possible is the aim of dietetics and regimen and the common-sense policy of every man who aspires to work to the best advantage. The enduring capacity of a man is measured by his weakest organ only. We are able by intelligence and self-restraint to spare this weak spot, and enable ourselves to tax our stronger parts to their full extent. The weak spot is commonly at some point in the assimilative process, but by no means *usually* in the stomach or intestines, or, at least, not manifested there most clearly. Whilst the original cause of the trouble may lie there, it very often shows itself in the subsequent changes, whether interstitial or metabolic. For instance, the absence of well-marked attacks of gout long blinded our eyes to the fact that the gouty diathesis is widely prevalent in this country. It is difficult to define gout, but it seems necessary to include under this head all that large series of cases with or without marked gastro-intestinal disturbances, in which there is obstruction to and deficiency of the ulterior assimilative changes before the food reaches its final fully digested forms.

He wished to call special attention to the great frequency with which, out of the presence of one or more of these causes, there is gradually evolved the complicated condition to which it is becoming the habit to apply the name of neurasthenia, and which is too often regarded as the result of pure nervous exhaustion from overwork, and therefore requiring simply tonics, rest, and high feeding. Such cases after they have been brought up to a certain point, require a protracted course of well-ordered regimen, dietetics, and exercise. Of course, one special method of treatment can be applicable only to one special group of cases, but it is the work of the skilled physician to discover to what group any special case belongs, and to select the method of medication best adapted to it. He alluded to the special methods employed by empirics, the system of Pressnitz, and those well-known methods employed at popular spas, the waters of which are totally inert. Although unscientifically employed, these methods do succeed in certain cases which have baffled the ordinary medical resources, and prove that remarkable results may be obtained by a systematic and oftimes extreme use of the simple agents—rest, exercise, food, drink, and bathing.

He spoke of the remarkable treatment called Schroth's Cure, now practised at Lindewiese, in Germany, which consists in an artificially induced attack of continued fever, developed by long-continued abstinence from water (thirty-six to ninety-six hours), and great restriction in diet and violent exercise, alternating with free stimulation. While undoubtedly hurtful in many cases, even this has been known to effect remarkable cures in constitutional syphilis, rheumatism, etc.

He remarked on the revival of the hot water mania, and said that the truth about it is that there are not a few cases of dyspepsia and lithæmia, of certain types of rheumatism, and gastro-intestinal catarrh, in which this remedy, combined with other simple hygienic measures, is the best cure. While hot water, taken as its advocates advise, is capable of doing harm, it will do good

in so far as it discourages the use of tea and coffee. We are advancing towards a time when for each carefully diagnosed group of cases there will be a scientifically adapted diet.

In illustration of these views, Prof. Pepper proceeded to give in detail several cases of great interest, in which patients suffering from severe disorders were greatly benefited, chiefly by attention to dietetics. One of his cases was a woman of 65, with all the symptoms of advanced fatty degeneration of the heart. Noticing that she had steadily increased in weight during her sickness, and was very fleshy, he put her on a reduced diet, and with proper medication effected entire relief of the symptoms in about nine months, during which time her weight decreased from one hundred and sixty-five to one hundred and forty pounds.

Systematic reduction is to be instituted only when symptoms clearly indicate it. When reasonable reduction of diet fails to produce a marked diminution in the weight, the patient has probably not too much weight. When body weight falls rapidly, even if symptoms subside commensurately, check it early to avoid debility. Care must be taken in reducing weight, lest a marked reduction might favor the development of some latent morbid tendency, such as tuberculosis, cancer, or scrofula. A reaction has commenced against the indiscriminate stimulation in disease advocated by Todd and his followers. In acute disease, to push stimulants and concentrated food beyond the power of the patient to assimilate, puts an additional burden upon his already weakened system. In chronic diseases, restoration of power, relief of symptoms, etc., can only be accomplished by thoroughly adjusting the diet and hygiene to the altered conditions of the state of nutrition, and then as far as possible directing our remedies to the actual indications.

DR. P. C. WILLIAMS, Chairman of the Section on Obstetrics and Gynecology, then read his report, entitled

THE USE OF ERGOT IN OBSTETRICS.

He began by considering the modern criticism upon the use of ergot in obstetrics, seeking to test this criticism by clinical facts that had come under his personal observation. Of all the fluctuations in the views of medical men, none has been more marked than in regard to the use of this drug. Many prominent obstetricians denounce its use under all circumstances in obstetrical practice. Dr. Engelmann, of St. Louis, considers it entirely unnecessary in midwifery, on the ground that grave accidents and serious injuries both to mother and child result from its use (rupture of uterus, lacerations, etc.). He would limit its administration to the non-pregnant womb. With these views Dr. Albert H. Smith entirely agreed (Amer. Gynec. Soc., Sept. 1883). Dr. Engelmann has just published in THE MEDICAL NEWS an account of two cases of rupture of the uterus, ascribing both cases to the use of ergot.

The literature of the subject presents a terrible picture of injury and death from the employment of this drug, and it requires some courage to place one's own personal experience against such an array of authority; but one can only speak of what one has seen and heard. Of course, all remedies powerful for good are powerful for evil, and the disasters referred to are generally from the improper use of the medicine. For example, take Dr. Engelmann's second case (the first case not being described with sufficient care). The lady had been under the care of a midwife, and had been four days in labor *with shoulder presentation*, when Dr. Engelmann was called. The rupture had already occurred. On the third day a physician, who had been called in, found the os dilated, but the parts rigid and dry; an arm in the vagina. He gave ergot in drachm doses, which he repeated thrice in the half hour. He endeavored to turn, but failed; another physician tried and failed. The patient was left with orders to continue the ergot. On the morning of the fourth day Dr. Engelmann was sent for, and found the condition the same as described, and the uterus ruptured. Child was removed by disarticulation, etc., and the mother died in two hours. Of course, ergot produced rupture in such a case. In cases also in which the position is normal, but the pelvis is deformed and the pains have ceased from exhaustion of the mother, or in which there is no deformity or malposition, but the membranes are ruptured, the parts hot and dry, and the progress of the case is slow, the employment of ergot is improper and disaster must result from it.

But is ergot, therefore, always equally destructive under all circumstances? According to Stillé's statistics of Prof. Busch's cases (of Berlin), in which ergot was given for weak labor pains, 1 child in 10 died; 1 in 8 of Chatto's cases died. Drs. McClintock and Hardy in 30 difficult labors used ergot in second stage and lost 20 children. Dr. West (in defence of ergot) admitted 1 death in 8 cases. These statistics (showing in all 1 death in 7 cases), Stillé considers conclusive evidence of the destructive effect of ergot on the child when used before the close of labor.

Dr. Williams considered that, appalling as these statements are, the danger is not inherent in the drug, but depends largely upon the conditions under which it is employed. He then gave his own statistics. In 1874 he had read a paper on the use of ergot hypodermically in post-partum hemorrhage. The success obtained in these induced him to use ergot thereafter in most cases to prevent hemorrhage, and the result vindicated the wisdom of the plan. Since that time he *has "never had a case of post-partum hemorrhage to deal with."* Since 1875 he has employed ergot in 210 cases, in 70 of these forceps were used, and in nearly all chloroform was administered. In these cases 215 children were born, with the following result:

1875,	41 cases.	No mother died and no child.	
1876,	22 "	No " " " " "	
1877,	15 "	3 mothers " " one "	(twins).
1878,	18 "	No mother " " " " "	"
1879,	21 "	No " " " no "	
1880,	25 "	No " " " one "	
1881,	21 "	One " " " " "	
1882,	22 "	One " " " two children.	
1883,	15 "	No " " " one child.	
1884,	10 "	No " " " no "	

Of the mothers (one death in forty-two), three died of puerperal convulsions, one from septicæmia, and one from exhaustion before it was possible to deliver. Of the children (one death in twenty-seven), two were twins and died from inherent debility; one was stillborn, the mother dying of uræmic coma, and being unconscious

when the doctor reached her; one, a foot-presentation, dead before seen; four were of immense size, and died from delay in effecting delivery. One of these died from an enormous hemorrhage caused by the mother leaping into bed on seeing the doctor's carriage stop at the door, the suddenness of the movement causing detachment of the placenta. The remaining three were so large and out of proportion to the pelvic capacity that death seemed inevitable. The ergot, it is fair to conclude, had nothing to do with any of these deaths. However this may be, these statistics stand in striking contrast to Prof. Stillé's, and show that the danger is not inherent in the drug, but is dependent upon the conditions under which it is given. In Dr. Engelmann's second case, the circumstances under which it was given made disaster inevitable.

Ergot should never be given in a *shoulder presentation*, or, on general principiples, in any malposition of the child, unless followed immediately by chloroform and other active intervention to terminate labor. It should never be given in the first stage of labor unless the os and vagina are fully dilated or easily dilatable—never in any stage of labor where the head is too large for the pelvis, unless forceps be used immedjately. It may be given in the first stage where the above-mentioned restrictions are not present. The same rules apply in the second stage (the vagina and perineum must be distensible and elastic). With the above restrictions it may be given in any stage of labor, when pains are feeble. In *every* case in which ergot has been given and the head ceases to descend, or recedes between the intervals of pain, forceps must be applied at once. Delay, under these circumstances, is a fruitful source of danger. It was failure to observe this rule that led to the frightful mortality in Drs. McClintock and Hardy's cases, tn which ergot was given and the labor left to itself without instrumental assistance.

It is Dr. Williams's custom to relieve the pain of childbirth in almost every case by the administration of chloroform, and as this drug is thought to weaken the pains and favor hemorrhage, he thinks it wise to be on the safe side, and, therefore, administers ergot, before giving chloroform, in every case in which it is not contraindicated by some of the conditions above mentioned. He also gives ergot to maintain uterine contraction after labor to guard against post-partum hemorrhage and against septic absorption. Since he adopted this rule (1875), he has had *no case of post-partum hemorrhage, and but one case of septicæmia.*

Dr. Opie, in opening the discussion, spoke of the difficulty of discovering by touch or other exploration the relation between the head of the child and the capacity of the straits. Should delay in relief by forceps occur after the administration of ergot, danger will ensue. The action of ergot is counteracted by full anæsthesia, so that we run the risk of hemorrhage before it acts when we give chloroform. Ergot does not act for about forty minutes.

Dr. Wilson said that he never gives ergot before delivery, except when certain that the child will be delivered in a few moments. It is impossible to tell whether delivery is possible; there may be unexpected difficulty. After labor, he uses it to prevent septicæmia; but, in his hands, it is not to be depended on for post-partum hemorrhage.

Dr. John Morris agreed fully with Dr. Williams. In two thousand obstetric cases he had only seen two deaths that could be traced to the use of ergot.

Dr. Branham drew attention to the fact that ergot causes danger to the child because it produces, not the normal contractions of the uterus, but tonic contractions. It is this faculty that makes it useful in the prevention of septicæmia and post-partum hemorrhage.

Dr. Williams, in reply, said that he had guarded the point of the danger of ergot in cases in which there was a disproportion betwen the head of the child and the size of the pelvis. In regard to the unexpected difficulties that might cause dangerous delay in the delivery of the child by the forceps after ergot had been administered, he would refer to his own cases: out of seventy deliveries by forceps, there were only three cases in which such delay could have caused death. In one case, only Cæsarean section could have saved the child. It was large, and the sutures of the cranium were firmly united. An examination of the causes of death in the remaining two instances convinced him that ergot had not caused it. By administering ergot before delivery, time is given for its full physiological effect to take place by the time the child is expelled. He did not think the entire absence of post-partum hemorrhage in his cases since he adopted his present practice (in 1874–75) could have been accidental.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

The American Medical Association will hold its thirty-fifth annual meeting in Washington, beginning on Tuesday, May 6th. The Association will be called to order in the Congregational Church, corner of Tenth and G Streets, at 10.30 A.M., by Dr. A. Y. P. Garnett, Chairman of the Committee of Arrangements, who, after the induction into office of the President-elect, Dr. Austin Flint, will deliver the Address of Welcome.

The Reports of the Committee of Arrangements, and of the Committee on Credentials will be presented, and then Dr. Austin Flint will deliver the Annual Address, after which the reports of special committees and new and miscellaneous business will be in order.

SECTIONS.

The Sections will meet in the afternoon at 2.30 o'clock, and the following papers will be read:

Section on Practice of Medicine (Main Hall, Room A, Congregational Church). A Contribution to the Clinical Study of Epilepsy, by Prof. William Pepper, of Philadelphia. Simulation of Pathognomonic Signs and Symptoms, by Edward G. Janeway, M.D., of New York. Dermatitis Herpetiformis, by Louis A. Duhring, M.D., of Philadelphia. The Etiology of Pericarditis, by James T. Whittaker, M.D., of Cincinnati. Importance of Uniformity in the Pharmacopœia, by D. W. Prentiss, M.D., of Washington. The Germ Theory of Disease, by H. O. Marcy, M.D., of Boston. The Production of Poisons by Microörganisms, by G. V. Black, M.D., of Illinois. The New Officinal Chlorate, by Traill Green, M.D., of Pennsylvania. Irritation of the Capsule of Glisson, by R. Harvey Reed, M.D.

Section on Obstetrics and Diseases of Women (Room B, Congregational Church). Desperate Surgery among Women; the Proper Field for It; Who Should and Who Should Not Attempt It; by R. S. Sutton, M.D., of Pennsylvania. Mechanical Methods and Appliances in Uterine Dislocations and Distortions, by H. F. Campbell, M.D., of Georgia. The Treatment Proper to Cancer of the Uterus, by W. M. Polk, M.D., of New York. Surgical Operation for Cancer of the Uterus, by W. H. Byford, M.D., of Illinois. The Effects of Trachelorrhaphy, by J. Taber Johnson, M.D., of Washington, D. C. The Rectal Diseases of Women, by Edward M. Jenks, M.D., of Illinois.

Section on Surgery and Anatomy (National Rifles Armory, 2d floor, Room C, G St. between 9th and 10th). Treatment of Compound Fractures, by Frederick S. Dennis, M.D., of New York. On Railroad Injuries of the Extremities of the Human Body, with Observations on the Site of Amputation and Subsequent Treatment of the Stump, by T. R. Varick, M.D., of New Jersey. Tracheotomy in Diphtheria, by Charles A. Leale, M.D., of New York. Amputation at the Hip-joint, with a Review of the Various Methods of Controlling Hemorrhage, by C. A. Wheeler, M.D., of Minnesota. The Excision of Nasal and Naso-pharyngeal Polypi by a New and Easy Method, by Joseph Ransohoff, M.D., of Ohio. On Twelve Months' Surgical Experience at the London Temperance Hospital, by A. Pearce Gould, M.D., F.R.C.S., of London.

Section on State Medicine (Room D, cor. 6th and F Sts.). Sensationalism and Dogmatism in Sanitary Matters, by H. Leffmann, M.D., of Pa. Jewish Hygiene and Diet, from the Talmud and other Jewish Writings, heretofore Untranslated, by C. H. VonKlein, M.D., of Ohio.

Section on Ophthalmology, Otology, and Laryngology (Room S, Congregational Church). Neoplasms of the Lachrymal Glands, by J. N. Mackenzie, M.D., of Baltimore. A Modified Prisoptometer, by T. E. Murrell, M.D., of Arkansas. A Case of Sympathetic Neuroretinitis, by Samuel D. Risley, M.D., of Pa. Diagnosis in Ophthalmology, by E. Williams, M.D., of Ohio. The Use of the Cresson Water in the Treatment of Catarrhal Affections of the Mucous Membranes of the Upper Air-passages, by Carl Seiler, M.D., of Pa.

Section on Diseases of Children (Room F, Congregational Church). The Significance of Bloody Discharges from the Bowels in Young Children, by F. Woodbury, M.D., of Pa. Septic Jaundice of Children in Parturition, by M. P. Hatfield, M.D., of Ill. Congenital Encephalocele, by J. H. Duncan, M.D., of Mo. Diphtheria, Based upon Analysis of One Hundred and Twenty Cases with a Mortality of Seven, by J. W. Brown, M.D., of New York.

Section on Oral and Dental Surgery (cor. 6th and F Sts.). The Removal of Tumors from the Upper Jaw, by Reuben A. Vance, M.D., of Ohio. Importance of, and Treatment for Assuring Healthy Dentine Over Endangered Pulps, by Jacob L. Williams, M.D., of Mass.

WEDNESDAY, MAY 7TH. GENERAL SESSION—10 A.M.

Announcement of Nominating Committee.

Report of the Committee on Securing more Competent Medical and Sanitary Service on Board Trans-oceanic Passenger Vessels, by A. N. Bell, M.D., Chairman.

11 A.M.—Address of the Chairman of the Section of Practice of Medicine, Dr. J. V. Shoemaker, of Philadelphia.

12 M.—Address of the Chairman of the Section of Obstetrics and Diseases of Women, Dr. T. A. Reamy, of Cincinnati.

New and Miscellaneous Business.

SECTIONS.

Section on Practice of Medicine. Clinical Study of the Heart Sounds, by Austin Flint, M.D., of New York. Primary Cancer of the Brain, by Roberts Bartholow, M.D., of Philadelphia The Pathology of Myocarditis, by Wm. H. Welch, M.D., of New York. The Dietetic Treatment of Diabetes Mellitus, by Austin Flint, Jr., M.D., of New York. Phthisis, Its Successful Treatment, by J. P. Miller, M.D. The Milk Treatment of Disease, by James Tyson, M.D., of Philadelphia. Irregular Apoplectic Attacks from Other Causes than Hemorrhage and Embolism, by Gaspar Griswold, M.D., of New York. Occult Cause of Disease, by W. L. Schenck, M.D. The Advantages of Massage in Rheumatic Gout, by Douglass Graham, M.D., of Massachusetts.

Section of Obstetrics: Puerperal Septicæmia, by Theophilus Parvin, M.D., of Philadelphia. Subject to be Announced, by George J. Engelmann, M.D., of St. Louis. A Contribution to the Relation of Ovulation and Menstruation, by A. Reeves Jackson, M.D., of Illinois. The Management of Protracted Labor, by Wm. H. Taylor, M.D., of Ohio. The Use of Hot Water in the Treatment of Cystitis in the Female, by S. C. Dudley, M.D., of Illinois. Does the Use of Ether in Parturition Increase the Danger to the Child, by Ellwood Wilson, M.D., of Phila. The Use of Chloroform in Labor, by J. Herbert Claiborne, M.D., of Virginia.

Section on Surgery and Anatomy: Tuberculosis of Bones and Joints, and its Treatment by Ignipuncture, by Roswell Park, M.D., of Buffalo. Is Carcinoma Mammæ Curable by Operative Procedures? by Charles B. Nancrede, M.D., of Philadelphia. An Earthy Calculus in the Substance of the Liver, by Wm. A. Byrd, M.D., of Illinois. On Bronchial Cysts of the Neck, by N. Senn, M.D., of Wisconsin. Intestinal Paralysis Consequent upon Acute Pressure, by P. S. Conner, M.D., of Cincinnati. The Treatment of Hydrophobia, Historically and Practically Considered, by C. W. Dulles, M.D., of Philadelphia.

Section on Ophthalmology, Otology, and Laryngology: Influence of Climate on the Treatment of Chronic Catarrh of the Middle Ear, by J. F. Fulton, M.D., of Minnesota. Epistaxis, by D. N. Rankin, M.D., of Pennsylvania. A Combined Visual and Astigmatic Test (Snellen's Type), Based on the Confusion Letters of the Astigmatic, by W. S. Little, M.D., of Philadelphia. Report on the Diseases of the Ear in Locomotive and other Engineers, Firemen, and Conductors, which may Endanger the Lives of the Travelling Public, by Laurence Turnbull, M.D., of Philadelphia. A Preliminary Report upon the Causes of Blindness, by C. M. Hobley, M.D., of Iowa.

Section on Diseases of Children: Remarks on the Feeding of School Children, by Louis Atlee, M.D., of Pennsylvania. Enlarged Tonsils, and How They Should be Treated, by Dudley S. Reynolds, M.D., of Kentucky. A Unique Case of Hydrencephalocele, by George W. Rachel, M.D., of New York.

Section on Oral and Dental Surgery: Sponge-grafting, by E. C. Briggs, M.D., of Mass. The Removal of Stains from the Teeth Caused by the Administration of Medicinal Agents, and the Bleaching of Pulpless Teeth, by A. N. Harlan, M.D., of Illinois.

THURSDAY, MAY 8TH. GENERAL SESSION.

Report of Committee on Nominations.

Report of Standing Committee on Meteorological Conditions and their Relations to the Prevalence of Disease. Also concerning the subject of Collective Investigation of Disease in coöperation with the Committee of the British Medical Association. By N. S. Davis, M.D., Ill., Chairman.

11 A.M.—Address of Chairman of the Section of Surgery and Anatomy, Dr. C. F. Parkes, of Chicago.

12 M.—Address of the Chairman of the Section of State Medicine, Dr. J. Roberts, of Nashville.

Report of the Treasurer.

Report of the Librarian.

Report of the Committee of Publication.

Miscellaneous Business.

SECTIONS.

Section on Practice of Medicine: Tuberculosis, by Henry F. Formad, M.D., of Phila. Retardation of the Pulse in Mitral Insufficiency, by A. T. Keyt, M.D., of Ohio. Specific Treatment of Diphtheria and Croup, by G. A. Linn, M.D. Muscular Hypertrophy of the Stomach, by Alexander Marcy, Jr., M.D. Etiology of Enteric Fever, by S. K. Crawford, M.D. Typhoid Fever, by S. K. Jackson, M.D. The Diagnosis of Tumors of the Anterior Mediastinum, by James C. Wilson, M.D., of Philadelphia. New Theory and Instrument of Diagnosis, by S. G. Ayres, M.D.

Section on Obstetrics: On the Management and Rectification of the Child's Head in Difficult Cases of Occipito-posterior Presentations, by I. E. Taylor, M.D., of New York. A Thousand Cases of Labor in Private Practice, and the Deductions to be Made from the Same, by W. M. Findley, M.D., of Pennsylvania. Causes and Prevention of Lacerations of the Female Sexual Organs, by S. D. Gross, M.D., of Phila. Malformation of the Female Sexual Organs Resulting from Arrest of Development, by B. B. Browne, M.D., of Maryland. Sudden Death in Labor and Childbed, by W. T. Lusk, M.D., of New York. Subject to be announced, by Robert Battey, M.D., of Ga.

Section on Surgery: A Case of Chronic Serous Synovitis of Knee, with Enormous Communicating Popliteal Bursa Extending to Tendo-Achillis, by T. F. Pruitt, M.D., of Missouri. Subject to be announced, by A. McLane Tiffany, M.D., of Maryland. Subject to be announced, by J. E. Owens, M.D., of Ill. Urethrotomia Lithotriptica, by M. Schuppert, M.D., of Louisiana. Treatment of an Obstinate Case of Club-foot, by E. H. Bradford, M.D., of Mass. Transfusion, by J. C. Hutchison, M.D., of Brooklyn. Entrance of Air into the Veins as a Secondary Cause of Death, by George S. Porter, M.D., of Conn.

Section on Ophthalmology, Otology, and Laryngology: Naso-pharyngeal Fibromata, by E. Fletcher Ingals, M.D., of Illinois. Observations on the Effects of Chronic Poisoning on the Nose and Adjacent Cavities, by J. N. Mackenzie, M.D., of Baltimore. Some of the Physical Causes of Asthma, by E. Cutter, M.D. A Simple Device for the Destruction and Removal of Tumors in the Naso-pharynx, by J. R. Upler, M.D., of Maryland.

Section on Diseases of Children: Bright's Disease of Malarial Origin, by I. E. Atkinson, M.D., of Maryland. Clinical Observations in Rötheln, by William A. Edwards, M.D., of Pennsylvania. Therapeutics of Infancy, by William Perry, M.D., of New Jersey. Practical Suggestions on the Treatment of the Malignant Forms of Scarlet Fever, by Bedford Brown, M.D., of Virginia.

Section on Oral and Dental Surgery: Overdraft of Nervous or Vital Power, as Affecting General and Special Health, by Jacob L. Williams, M.D., of Massachusetts. Periodic Hemorrhage from the Gums, Associated with Pyorrhœa Alveolans, the Result of Amenorrhœa, by W. Wallport, M.D., of Illinois.

FRIDAY, MAY 9TH. GENERAL SESSION.

Concluding Report of Committee on Nominations.

Address of the Chairman of the Section on Ophthalmology, Otology, and Laryngology, Dr. J. F. Chisolm, of Baltimore.

Address of the Chairman of the Section on Diseases of Children, Dr. Wm. Lee, of Baltimore.

Miscellaneous Business. Adjournment.

Entertainments.—The evenings will be occupied by a reception by the President of the United States, a reception by the medical profession of Washington, and several card receptions at private residences.

MEDICAL MATTERS IN CONGRESS. BUREAU OF LABOR AND STATISTICS.—The bill to establish and maintain a "Bureau of Labor and Statistics," which passed the House on the 21st inst. after considerable discussion by a vote of 183 ayes to 19 nays, provides for obtaining "the number and ages of children, nature of their occupation, the effect of different kinds of labor on their growth, development and health; the sanitary, educational, social and moral condition of laborers; the average duration of life; accidents incident to employment; insanity; epidemics; factory, mill, mine, and dwelling inspections; and the condition of tenement houses for operatives and the rental thereof."

ADULTERATION OF FOOD AND DRUGS.—A resolution, introduced on the 21st inst. by Mr. Beach, of New York, Chairman of the Public Health Committee of the House, authorizing the Committee to "inquire into the extent and character of the Adulteration of Food and Drugs imported into the United States, or exported therefrom," brought on an animated discussion between the chairman and Mr. Mills, of Texas. The resolution was finally defeated.

THE MEDICAL AND SURGICAL HISTORY OF THE WAR.—A joint resolution introduced by Mr. Scales, of North Carolina, on the the 21st inst. was agreed to, authorizing the Public Printer to print such number of copies of the *Medical and Surgical History of the Rebellion* and the *Rebellion Record* as he may receive orders for, accompanied by the cost price of the publication and ten per cent. additional, when such orders are sufficient to justify the expense of putting the plates to press. The tenth census and compendium were also included in the above resolution.

THE EMPLOYMENT OF DIFFERENT SCHOOLS OF MEDICINE IN THE GOVERNMENT SERVICE.—The homœopaths flooded the Senate on the 21st inst. with petitions and memorials praying the passage of Senate bill 1223, re-

quiring the Employment of Different Schools of Medicine in the Government Service.

Mr. McPherson, of New Jersey, explained the petition presented by him to mean that all grades of physicians and all classes, as allopathic, homœopathic, etc., should be made equal before the law in the Government Service of the United States. Petitions to the above effect were presented by Mr. Cameron of Wisconsin, Mr. Hawley, of Connecticut (whose petition was headed by Ex-Governor Wm. T. Minor, and signed by 117 others), by Mr. Cullom, of Illinois, who presented sundry petitions of citizens of Chicago and other cities of Illinois, Iowa, and Minnesota, by Mr. Harrison, of Indiana, and Mr. Cockrell, of Missouri. The latter gentleman also presented a memorial from the faculty and students of the Homœopathic Medical College of Missouri, protesting against the discrimination that is made in favor of one class of physicians alone in Government employment in all the offices except the Pension Office, and recommending the passage of the bill referred to above. All the petitions were referred to the Committee on Civil Service and Retrenchment.

INTRODUCTION OF INFECTIOUS DISEASES.—Mr. Palmer, of Michigan, presented resolutions of the State Board of Health of Michigan favoring legislation for the prevention of the introduction of infectious diseases into the United States, which was referred to the Committee on Epidemic Diseases.

THE SEVENTH REPORT OF THE GERMAN CHOLERA COMMISSION.—DR. KOCH, in his seventh report, dated Calcutta, March 4, and published in the *Deutsche medicinische Wochenschrift* of April 3, says that it is a surprising fact that the cholera, in its endemic sway, was very often confined to fixed localities, and it was at the same time evident that it was epidemic to a certain extent. Especially frequent were these small localized epidemics in the vicinity of the so-called tanks (these tanks, from which water is used for almost every purpose, are extremely numerous over the whole of Bengal). It is easily understood that, the water, being often left in the tanks after being used, becomes foul and is entirely unfit for use. It very often happens, also, that the latrines, if contrivances of the most primitive kind can be so called, are built on the banks of these tanks, and their contents find their way into the tanks, while the banks serve as repositories for every kind of filth and especially for human fecal matters. The tanks contain, therefore, as a rule, very filthy water, and it is under those circumstances accountable that the resident physicians should seek to establish a relation between an epidemic of cholera near such a tank, and the bad quality of the tank-water. These tank epidemics are not at all infrequent, and every physician who has a large experience with cholera knows of a greater or less number of examples. On this account I have from the beginning directed my attention to this point, and have requested the sanitary commissioner to inform me if any such epidemic should occur near Calcutta. Such a case occurred during the past week. At Saheb Bagau, near Calcutta, there were, during a few days, an unusual number of cases of cholera. The cases were confined to the immediate vicinity of one tank around which a few hundred persons lived, and there were seventeen fatal cases; whilst at a distance from the tank and in the whole surrounding police district there were no cases.

It is noteworthy that this same place was visited with cholera last year. At the beginning and during the course of the epidemic, the Commission made careful examinations, and found that the tank-water was used, in the usual manner, for bathing, washing, and drinking purposes, and that the soiled clothes of the cholera patients were cleansed in the tank. A number of examinations were made of water from different parts of the tank, and at different times, and investigated by the aid of gelatine cultures; cholera bacilli were found in tolerably large numbers in the first examinations. Later, when the epidemic was at an end, other examinations were made, and very few cholera bacilli were found in one tank only, and that in an especially filthy place. When it is considered that many examinations of tank-water, sewage, river-water, and various specimens of dirty water were made, and cholera bacilli were found only in a tank around which cholera was raging, these results must be regarded as most important. It seems established that the water in the tank was infected by cholera-washings which contained cholera bacilli in large numbers; further, it was shown that the dwellers around the tank used this infected water for house purposes and drinking-water. This furnishes, in a degree, the proof, which could not be obtained by experiments on animals, that the specific cholera bacilli are the cause of the disease.

This is one way, then, in which the cholera poison gets into the human system, and I do not doubt that in other similar cases the proof of the cholera bacilli in the water or other vehicle of the infective principle will be established.

Since my last report twenty cholera cadavers and the dejecta of eleven cases have been examined, which gives a total, of the examinations thus far made in India, of forty-two cholera cadavers, and twenty-eight cholera patients. These last cases have given no new results; they were precisely similar to the former.

Experiments have been made as to the influence of various substances, such as corrosive sublimate, carbolic acid, and other disinfectants on the development of the cholera bacilli in culture fluids, and also as to the behavior of the bacilli in carbonic acid gas and when excluded from the air. Experiments were also made with a view of discovering a permanent form (Dauerform) of the cholera bacillus, but so far nothing of the kind has been found. The single possibility, of causing the cholera bacilli to retain their viability for a long time, consists in their being preserved before becoming dry. In fluids they remain capable of development for a week, and everything seems to show that if they have only remained in a damp place and get into the human system they become active.

Further observations on this subject have now become very difficult on account of the hot weather. Last week the temperature was so great that it was only with the greatest difficulty that work could be carried on in the laboratory, and nothing can now be done except to end the work.

THE STATE MEDICAL SOCIETY OF ARKANSAS will hold its ninth annual session at Little Rock, on Wednesday, April 30th, and the two following days.

ORIGINAL LECTURES.

CHRONIC NASAL CATARRH.

Two Clinical Lectures,

Delivered at the College of Physicians and Surgeons, New York.

BY GEORGE MOREWOOD LEFFERTS, M.D.,

PROFESSOR OF LARYNGOSCOPY AND DISEASES OF THE THROAT.

LECTURE II.

GENTLEMEN: A very essential principle in the local treatment of catarrhal affections of the nasal passages is thorough cleanliness; it underlies all others. There certainly can be little remedial value in the application of a medicated spray or powder that only reaches parts covered and protected by a layer of thick, tenacious mucus, or, still less, those encased in an armor of hard, inspissated crusts. On the other hand, I am convinced that this matter of cleanliness, if the latter be understood to mean frequent, daily, even several times a day, syringing of the nose, is overdone, and that it does much harm. The comfort, fancied or real, that a patient experiences after the use of his "nasal douche," even though this relief be only temporary, as it always is, leads him to repeat the process with constantly increasing frequency. Instances are not unknown where patients will use a quart of a strong saline solution under high pressure, through the nose several times daily. Physicians are not entirely guiltless in the matter, for it is not infrequently that the patient is misled by their belief that the cure of a nasal catarrh lies in the use of a "douche." Such practices, I repeat, are productive of no good, but much harm. Even apparent, temporary good effects ultimately fail. The use of strong saline solutions in large quantity, passed through the nares under high pressure, is not infrequently an efficient factor in the propagation if not in the causation, as I believe that I have many times seen it, of a chronic inflammation of the delicate nasal mucous membrane, with its usual result of permanent infiltration of the mucous and submucous structures. All this rather than a means for its relief.

While, then, cleanliness is essential, mechanical means for attaining it are to be used with great discretion. There is nothing curative in their employment, bear that in mind. They are by no means as generally necessary as was formerly supposed. I believe that in my practice I have discontinued their use in more than fifty per cent. of cases, and the latter not only do just as well, but better, being relieved of an element of irritation. All instruments then for cleansing purposes, and I include here the "nasal douche" with its many modifications, anterior and posterior nasal syringes, and the like—I even add cleansing sprays—are only necessary and are only to be used in exceptional cases of aggravated catarrhal inflammation, with accumulation of pent-up or hardened secretions, and in cases attended by the formation and firm impaction in the passages of hard, dense crusts, as in atrophic or fetid catarrh and in ozæna. In simple chronic rhinitis, and in some—perhaps one-half—of the cases of hypertrophic rhinitis their use is not required as a rule. The patient can readily remove the soft, semi-fluid secretions by simply blowing the nose; if he cannot, or if the secretions collect at the vault of the pharynx, one jet of spray containing some alkali or some "Listerine," thrown by you behind the velum or into the anterior nares, just prior to the use of the medicated spray or powder of which I shall speak in a moment, will be amply sufficient to loosen and remove them.

Let us suppose, however, that you are called upon to treat a case such as I have described, where the use of some instrument is a necessity in order that the pent-up or hardened secretions may be removed before you make your application of the remedial agent. What form of instrument shall you use? Which method prefer? Never use a "nasal douche," it is an inefficient instrument for the purpose for which it was designed, insomuch as it does not thoroughly wash or cleanse the nasal cavities, even when carefully used. I prefer, and I strongly advise you to employ, the instrument that I show you here, and which I devised some years ago. It is simply an apparatus arranged to throw a *very coarse spray* in the right direction into the anterior nares. The conical tip you see, closes one nostril completely, the fluid then enters one nasal passage and passes out by the other. Power is obtained by means of a double hand-ball tube. We call it the "nasal spray apparatus." With it the nasal passages and upper pharynx may, except in rare instances, be thoroughly cleansed of secretions and crusts by the use of less than one ounce of the medicated fluid, contained in its bottle or reservoir. Here, at once, is an immense advantage gained over the pint or even quart of fluid used commonly in the "douche." Being a *coarse spray* it washes up, loosens, and dislodges the secretions (unless they are firmly impacted in extreme cases) by the constant commotion of the fluid in the nasal passages, and this very readily and quickly. Explicit directions are to be given in every case to the patient for its use. I have had them printed, and now distribute them to you, they also accompany each box in which the instrument is sold.

In the severer forms of nasal disease—those attended by the formation and impaction of hard, dense crusts and masses in the nasal passages and upper pharynx—the use of this "nasal spray apparatus" will not be sufficient to dislodge them in the first instance, and a more powerful means (short of direct instrumental removal) must be employed. This result is best obtained by the "posterior nasal syringe," of hard rubber or metal, with a long, curved nozzle, which is used to cleanse the parts posteriorly (by way of the upper pharynx and posterior nares). This procedure is always disagreeable, sometimes painful, to the patient, and care must always be taken not to bruise the parts during the introduction of the nozzle of the syringe. Toleration will be established after a time. For cleansing purposes

through the anterior nares—an easier matter—the large, hard-rubber syringe of the aurist answers the purpose well.

Various cleansing and disinfecting solutions may be used by means of these instruments. I use with the "nasal spray apparatus," either one of the following: acidi carbolici, ℈j (this quantity is necessarily often varied to suit the susceptibility of different mucous membranes); sodæ biboratis and sodæ bicarbonatis, āā ℥j; glycerinæ and aquæ rosæ, āā ℥j; and aquæ, ad Oj; or, still better, sodæ bicarbonatis and sodæ biboratis, āā ℥ss; "Listerine," ℥j; and aquæ, ad ℥iv.

The "Listerine," in the latter formula, may not be familiar to you. It is a preparation that has lately been introduced by Lambert & Co., of St. Louis, containing the essential antiseptic constituent of thyme, eucalyptus, baptisia, gaultheria, and mentha arvensis in combination. Each fluidrachm also contains two grains of refined and purified benzo-boracic acid. Thus it may be used in this or in any of the other solutions of alteratives, astringents, and resolvents of which I shall have to speak (usually in combination with some proportion of water—2-10 to one part "Listerine," according to the indications), as a menstruum, and will be found to serve a useful and pleasant purpose where an antiseptic is desirable. The thyme and eucalyptus, besides being disinfectants, act also as stimulants to the mucous membrane. Where a much larger quantity of a cleansing solution is necessarily used, as with the anterior or posterior nasal syringe, simple warm water, with the addition of borax—ten grains to each ounce—or "Listerine" in the proportion of one part to from two to ten of warm water, will answer the purpose. I sometimes—when the disagreeable odor is strong—use, after a thorough syringing with an alkaline solution, a *spray* of equal parts of "Listerine" and water; it destroys fetor very quickly, and substitutes for it the pleasant odor of the thyme.

Let me say here—what you have probably noticed—that I use no sodium chloride in any of these cleansing solutions; I believe that it does more harm than good, that the saline solution favors endosmosis as it passes over the nasal mucous membrane, and therefore increases rather than diminishes intra-nasal swelling.

Having shown you now how the parts may be cleansed, if this be necessary, I turn to the question of the direct *medication* of the disease which affects them. If I exclude for the moment the use of caustics and of surgical measures in the management of catarrhal conditions of the nares, the treatment is based practically either upon the employment of various *medicated fluids* used in spray by means of some form of atomizer, or upon the use of *medicated powders*, applied with the anterior or posterior nasal powder-insufflator in one of its various forms. Both methods have their warm advocates. My own experience prejudices me strongly in favor of the *spray*. I believe that with a proper spray-tube, and a pressure of compressed air of about forty pounds to the square inch, no more perfect application can be made to the parts. This should always, if possible, be through the posterior nares. The patient depressing his tongue by means of a spatula, the velum palati must be drawn forwards, that is, away from the posterior pharyngeal wall, by means of a suitable metal hook covered by bougie material, a procedure that can be readily accomplished in *all* cases after a little practice, and one that I regard as *absolutely essential* to the thorough success of the application, as it is the only way in which a practicable degree of space can be gained through which to throw the spray upwards and forwards through the nasal passages. To attempt an application with the velum drawn upwards and backwards closely approximated to the pharyngeal wall is nonsense. In this position it will be found the moment that you introduce your spray-tube into the patient's mouth in nine cases out of ten. The palate-hook is held in the operator's left hand, his right holds the spray-tube, and the spray is thus thrown upwards into the vault of the pharynx and forwards through both nasal passages, so that it appears at both nostrils in a fine cloud. Such an application is thorough and complete, not painful nor even very disagreeable to the patient. That the results obtained by a series of such, far exceed those obtained by any other method, ample experience has shown me.

I prefer the high pressure of compressed air to the lower power, so often recommended. I have never done harm to the mucous membrane with it, and the increased power of propulsion in the cloud of spray renders it possible to reach all of the many irregularities and recesses abounding in the naso-pharyngeal passages. I say nothing here except in condemnation of the practice of *forcing* a probe or cotton-holder, charged with a solution of nitrate of silver, up behind the velum in spite of the violent muscular contraction of the parts, or of the use of small brushes, called "post-nasal," used in the same way, which, from their very size, form, and length, render it a physical impossibility to reach the vault of the pharynx, still less the posterior nares, or to enter the latter; medication by such means amounts to little.

But it is hardly to be expected that the general practitioner will be able to command the use of a costly compressed-air apparatus with air-pump and spray-tubes, such as I show you here; then in default of this apparatus, the ordinary "hard-rubber atomizers," which can be bought at a moderate price everywhere, and which are constructed upon the principle of either Richardson or Bergson, must be used, and can be, with good effect. A very good atomizer is manufactured by the Davidson Company, and called Hard-rubber Atomizer, Continuous Spray, No. 61. In all, the propelling power is developed by the use of the hand air-bulbs; these should always be double. The hard-rubber tube of the instrument is provided with two separate tips, so that the spray may be thrown upwards (naso-pharynx), or directly forwards (anterior nares). The disadvantages of this instrument, which make it inferior to the use of the compressed air apparatus, are the length of time that it takes to develop the propelling power by means of hand-ball pressure, an important point when the instrument is in position in an irritable throat, and the fact that both the operator's hands are required to work it, and that, therefore, he cannot use the "palate-hook" to draw the velum forwards. You will rarely find a patient with a throat tolerant enough to allow you to throw the spray, with this instrument, up into the vault of his pharynx and posterior nares without the use of the "palate-hook," and you had better, therefore, confine yourself to applications made through the ante-

rior nares and forced well back into the pharynx, if you use it.

The most useful forms of powder-insufflator I show you here. One, you see, is arranged to deliver, by means of the air-pressure developed by these hand-balls, a charge of the finely pulverized powder with which the bottle is charged into the anterior nares; the other, with a longer curved tube, performs the same operation in the posterior nares.

Personally, I place very little reliance on the various "pocket inhalers," etc., that are popularly recommended for the cure of "catarrh." Ammoniated and iodized preparations sometimes exercise a temporary benefit, but they can also readily do harm, if used to excess. Remembering this, if you choose to recommend them for the moral effect they exercise upon your patient, I have no objection.

I ask your attention now to the specific *remedial* treatment of the various forms of rhinitis. *Simple chronic rhinitis* requires, first, thorough preliminary cleansing of the passages. This may be accomplished usually by the patient using his handkerchief, unaided by any artificial form of apparatus. If the latter, in exceptional instances, be requisite, use the "nasal spray apparatus," with one of the given solutions. The post-nasal syringe is never required in this form of the disease. Following the cleansing process comes the remedial, which must be undertaken by physician or patient, with at first daily, and then gradually diminishing frequency, until, at length, a time is reached (after several weeks) when the patient is told to present himself for treatment only when he develops, if he should, a recurrence of any old symptoms, or an attack of acute rhinitis. This consists in the application of the medicament, usually a mild alterative, resolvent, or astringent solution or powder. If the *spray* apparatus, with compressed air, and some medicated solution, be chosen as the means, as I advise, some one of the following formulæ may be used, with preferably the *post-nasal* spray tube, but also with the anterior, or both. If the "hard-rubber atomizer" is the only instrument available, then the spray is thrown through the anterior nares. 1. Zinci iodidi, gr. v–℥j; 2. Zinci sulpho-carbolatis, gr. v–℥j; 3. Zinci sulphatis, gr. v–℥j; 4. Ferri et ammoniæ sulphas, gr. v–℥j; 5. Ferri perchloridi, gr. v–℥j; 6. Acidi tannici, gr. v–xx–℥j; 7. Potassæ chloratis, ℈j–℥j, are the solutions that I most commonly use, given in the order of their preference. In any of these formulæ, "Listerine" may be substituted, in part, for the water, in the proportion of one part of the former to three of the latter. I ordinarily do so. If the simple rhinitis has advanced far towards the hypertrophic stage, then I commence at once with: Iodini cryst., gr. iv; Potassæ iodidi, gr. x; Zinci iodidi, ℈j; Zinci sulpho-carbolate, ℈j; "Listerine," ℥j; Aquæ, ad ℥iv, as a spray. These applications should always be selected with due deliberation, in view of the special indications presented by the case, care being exercised that the application is of such a strength as to cause *no irritation* of the nasal mucous membrane, one much more susceptible than that of the pharynx or larynx. A preliminary trial of the strength of the solution should always be made.

In case these spray-applications are not well borne, or perhaps in accordance with the special views of the physician, a medicated powder may be substituted. Powders are particularly adapted to the treatment of this form of the disease, where the secretions are readily removable, the parts soft and absorptive. In hypertrophic rhinitis they are, I believe, of little use, and in atrophic or fetid rhinitis contra-indicated. One such powder as, for instance, the following, may be applied by means of the anterior, or, if possible, the posterior nasal powder-insufflator that I have shown you: Acidi salicylici, gr. x; acidi tannici et bismuthi subcarb., āā ℥j; or this, Ferri et ammoniæ sulph., ℈j; pulv. amyli, ℥j. Other combinations will suggest themselves.

Whatever be the plan of treatment instituted, not alone in this but in the other forms of rhinitis as well, and its details may readily be determined upon from what has and will be said. It is to be *steadily persevered in*, not necessarily in all cases under the direct manipulation of the physician himself, but certainly in all cases under his general supervision, and at suitable intervals, which will vary according to the grade of the disease, until the morbid conditions for which it was undertaken are alleviated. Daily applications at first, then three times weekly, then twice, and finally at increasing intervals dependent upon the indications, until a period of at least eight to ten weeks has been covered, will be the rule. The necessity even now for the immediate treatment of any subsequent recurrence of old symptoms, which will quickly yield, and for any attacks of acute rhinitis, which may or may not occur, I have spoken of. All this is tedious to the patient, I know, but, Gentlemen, there is no royal road to the successful treatment of nasal catarrh.

In speaking to you now of the treatment of the next form—*hypertrophic rhinitis*—all that I have just said is applicable to its earlier stage, except that instrumental cleansing will often be requisite; that occasional use of the post-nasal syringe is a necessity; and that I prefer to commence at once with the formula of iodine, iodide of potash, zinc, etc., that I have given you. If the disease is moderate in extent, and the hypertrophy of the tissues not excessive, complete resolution may be effected by these means. On the other hand, if the process be first seen, as it so often is, in its advanced stages, when a firmly organized neoplastic tissue exists in a large degree, and seriously encroaches upon, even occludes, the nasal cavities, associated with a chronic inflammation involving the greater part of the upper pharyngeal mucous membrane, and hypertrophy of the adenoid tissue at the vault of the pharynx, the above plan of treatment, as a curative means, is *useless;* some alleviation of the more prominent symptoms may be obtained, but more heroic measures will be required to cure, chiefly the use of some means by which the hypertrophied membrane and tissues can be destroyed. I am bound to admit that it is in the use of these means, mainly surgical, and in this form of rhinitis, that you will attain your most speedy, complete, and brilliant cures. The destructive agents that are at your command are fuming nitric acid, glacial acetic acid, chromic acid, the galvano- or actual cautery, and nitrate of silver. These I have mentioned in the order in which I would select them for use in any case. I now add the Jarvis écraseur, and, for the adenoid growths of the pharynx, the post-nasal forceps.

The little operation that I am about to describe to you first, is one that you will often find necessary; you can

readily perform it, and I assure you that it will give most gratifying results.

Let us suppose a case of hypertrophic rhinitis in which you find the hypertrophied mucous membrane located mainly over the inferior turbinated bone, in one or both nasal passages; there is partial, intermittent, or permanent occlusion occasioned by its presence. Take a small probe, its end wrapped in absorbent cotton, and saturate this with *nitric acid*, press out the excess of acid, pass it then through a suitable nasal speculum into the naris to be operated upon, under the guidance of a good reflected light from your forehead mirror, and with a steady hand now draw it along, or press it firmly upon, the turbinated bone at its point of greatest convexity, contact being kept up for a few seconds. The pain quickly passes away, and on withdrawing the probe the parts are seen to have become well whitened or blanched; moderate inflammatory reaction with a slough of varying depth follows, while the consolidation of the sub-mucous tissues by the hyperplastic results of the inflammatory process, and the contraction of the cicatricial tissue occupying the site of the destroyed parts, serve to reduce the hypertrophy and its resultant nasal obstruction in a most satisfactory manner. Frequently, one application answers all purposes in freeing the nasal passage to the extent of allowing of uninterrupted respiration. The process, however, may require repetition.

The operation with *glacial acetic acid* is performed in the same manner; it is less painful, causes little secondary inflammation, and destroys less tissue. This agent, then, may be selected for the more moderate and more recent cases of hypertrophy.

Chromic acid is less painful in its use than nitric; its fumes, though, are distressing to the patient. It possesses no advantage, for our purpose, over the other two.

The *galvano- or actual cautery*, either for the destruction of tissue in the nasal passages or at the vault of the pharynx, is, of course, a radical and efficient agent. I allude to the former; the latter is hardly ever used. Its action is rapid, complete, and not very painful; but as its use requires much skill, especially when employed in the naso-pharyngeal region, you will probably prefer to entrust such cases to the hands of the specialists. Instances where it will be required are not very many, for I believe that we may accomplish the same results with less heroic means. A full description of the instruments, and the method of using them, will be found in most works on diseases of the throat and nose, and to these I refer those of you who care to pursue the subject.

Nitrate of silver, as a destructive agent, I mention but to condemn. It causes but a superficial slough, and the application is of necessity frequently repeated in treating hypertrophied tissue of any extent; moreover, owing to its powerfully stimulating qualities, it excites cell proliferation, and causes structural changes that are not desirable.

After the use of any form of *caustic* in the nasal passages, immediately upon the withdrawal of the probe, the parts should be flooded with an alkaline solution. The subsequent treatment of the case, at least until the slough has separated, and the resultant ulcer healed, is based upon ordinary principles of cleanliness.

Now, there are two forms of hypertrophy of the tissues over the inferior turbinated bones that are occasionally met with clinically, and which cannot be successfully treated by any of the methods of which I have thus far spoken. The operations for their relief need then a special description. You will be able to perform them readily when you have acquired a little skill in intranasal surgery. There is no reason why you should not attempt them. The *first* is where the hypertrophy is *excessive* and is mainly limited to the *anterior extremity* of the turbinated bone; to remove it, which you must do surgically, the procedure devised by Dr. Jarvis should be undertaken. The growths are usually sessile, but can be readily engaged in a loop of fine steel wire passed through a delicate *écraseur*, devised by the same surgeon, if their base be first transfixed with a slightly curved needle, until the point projects above the growth into the nasal cavity. The wire loop is then arranged in such a manner that the portion of the needle projecting from the nostril, as well as the needle's point, is encircled by it, very much after the manner of a hare-lip suture. The wire loop is thus prevented from slipping off, and a portion of the hypertrophied tissue is readily secured, and is removed by screwing down the milled nut of the *écraseur* and drawing the wire home. This little operation is quickly done, and is not very painful or bloody; the relief that it affords is great.

More common than the above, is excessive localized hypertrophy of the mucous membrane covering the *posterior extremities* of the inferior turbinated bones. It may be, as I told you in the first lecture, of such an extent that nearly the whole posterior naris is occluded by an irregular, grayish or whitish, sessile tumor, which projects outwards into the free space of the pharynx. Owing to its peculiar position it cannot be safely reached and destroyed by any caustic method, removed it must be to cure the patient. The small *écraseur* already mentioned, here again affords a satisfactory and efficient means for its entire extirpation. The instrument is passed through the nasal passage upon the affected side, the size and location of the growth having first been carefully studied, and the form of the wire-loop arranged accordingly, and no great difficulty will be experienced in ensnaring it. Slight traction on the instrument, and a few turns of the milled nut will now receive it firmly in the loop, and the mass is then *slowly* cut through by tightening the wire. This little operation alone, if judged by its results, constitutes one of the most marked advances of recent rhinoscopic surgery.

Still another special operation is required in cases in which the hypertrophy of the *glandular structures* at the vault of the pharynx is excessive, as is so often seen in young subjects, the victims of a hypertrophic rhinitis. The tumor thus formed, which we term *adenoid tumor* or *adenoid vegetations*, varies, as I have said, greatly in size and configuration, but if it be large enough to interfere with nasal respiration, if it modify the voice, and threaten danger to the middle ear by pressure upon the Eustachian orifices, if it give rise to excessive secretion and cause general discomfort to the patient, there is no question but that its removal is indicated. On the other hand, I would warn you against the too ready and indiscriminate extirpation of these

tumors. A certain degree of thickening of the tissues at the vault of the pharynx is not an uncommon condition in young children, who suffer from no symptoms of nasal catarrh. Again, this structure atrophies normally towards puberty. To interfere with it surgically, therefore, simply because it exists, seems to me to be a grave mistake.

Should you determine, however, after what I have said, that its removal in a given case is proper, resort at once to surgical measures, for medicated sprays are totally ineffectual, and caustics are of little use, as well as difficult of thorough application. A pair of long forceps, such as I show you here, suitably curved, to be passed behind the velum and furnished with cutting blades at their extremity (Woakes' forceps, modified by Semon), will be the best means. With them you may undertake the operation with confidence, even though you possess but limited experience. With care and some anatomical knowledge you can do no harm to contiguous parts; the operation, seemingly formidable, is, in reality, simple. Hemorrhage is slight, ceases spontaneously, and inflammatory reaction is never such as to excite any apprehension—at least, such is my experience. When the hypertrophy of the tissues extends broadly, in the shape of small, slightly elevated nodular masses, over the entire pharyngeal vault, a sharp curette such as is used in uterine operations, but suitably curved to pass behind the velum into the upper pharynx, will answer a better purpose in scraping away the vegetations than the forceps, which would here be difficult of exact application.

I need not detain you long in speaking, in conclusion, of the local treatment of *atrophic* or *fetid rhinitis*. Unfortunately, the disease is beyond our powers of cure. The best that we can promise the patient is to mitigate his urgent symptoms. I am well aware, in making this statement, that some profess to cure; I have not been so fortunate as to obtain this result. Our indications for treatment are twofold: first to cleanse and disinfect, and then to keep clean and disinfected, the nasal passages of all decomposing crusts and secretions; and, second, to stimulate the atrophied mucous membrane, with a view to the regeneration of function and character of secretion in the muciparous follicles and serous glands, if this latter can be accomplished, a matter which my experience has led me strongly to doubt. The first indication is met by the daily use of the anterior or post-nasal syringe, occasionally by the necessary direct removal of hard crusts by means of forceps, and thorough washing of the passages with an antiseptic and alkaline solution until all offending secretions are removed. I have given you some formulæ suitable for this purpose; others are: glycerini acidi carbolici, ʒjss; sodii biboratis, ʒj, aquæ, Oj: liquoris potassi permanganatis, ʒjss, sodii biboratis, ʒj, aquæ, Oj: acidi salicylici, gr. x, sodii bicarbonatis, ʒj, aquæ, Oj. I, as well as my patients, prefer the solution with "Listerine," given above.

The second indication requires the use of such drugs as sanguinaria, galanga, carbolic acid, creasote, salicylic acid, iodine, bromide of potassium, etc., which are recommended by Dr. Bosworth as efficient in the early stages of the disease. They are mentioned in the order of preference, and should be used in solution, by means of the atomizer. They probably act by giving rise to a local irritation of the mucous membrane, which in turn leads to a stimulation of the glandular structures, and an increased discharge of serum and mucus. Dr. Seiler advises, on the contrary, nitrate of silver in powder diluted with starch, and says that it has given him good results. As next in effectiveness, he recommends the use of a weak solution of the sulphate of iron and ammonia. My own experience with any of these means has been limited; such as I have used have been ineffectual in their results, and I can therefore only reiterate my belief that, in the present state of our knowledge, the disease is incurable.

This finishes, Gentlemen, what I have to say to you upon this special subject of chronic catarrhal diseases of the nose. My remarks have, necessarily, been drawn out to some length, and have occupied some time; if, however, I have succeeded in convincing you that *all* is *not* simply "nasal catarrh" that comes to your net, if I have taught you to recognize, by my descriptions, the various forms of chronic rhinitis, and shown you how to treat each intelligently, according to its individual indications, the time will not have been misspent, and the purpose of these lectures has been accomplished.

ORIGINAL ARTICLES.

WOUNDS OF THE INTESTINES.[1]

BY S. D. GROSS, M.D., LL.D., D.C.L. OXON., LL.D. CANTAB., EMERITUS PROFESSOR OF SURGERY IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

THERE are few topics in surgery that have received less attention than the nature and treatment of wounds of the intestines. Even our text-books say very little upon the subject, and that little is seldom founded upon original observation. When we consider the frequency of these lesions, their great gravity—if not almost uniform fatality, and the doubts and misgivings with which they are approached by most practitioners, it will not require any apology on my part for bringing the matter formally before this meeting.

While every other branch of surgery has been enriched by papers and monographs almost in countless numbers, the literature of wounds of the intestines is exceedingly scanty, and, in many respects, unsatisfactory. The older writers have transmitted to us nothing of value, and even as late as the close of the last and the beginning of the present century not one of our systematic writers had any fixed or settled notions upon the subject. The author who came nearest to this was Benjamin Bell, of Edinburgh, whose *System of Surgery*, in six octavo volumes, published nearly one hundred years ago, did much to diffuse a taste for surgery, not only in Scotland and England, but on the Continent of Europe and in the United States. It is an interesting fact that the first foundation of a rational treatment of lesions of this kind was laid in this country in 1805, by Dr. Thomas Smith, of St. Croix, in his *Inaugural Dissertation*, presented to the Faculty and Trustees of the University of Pennsylvania. His

[1] Read before the American Surgical Association, April 30, 1884.

experiments, twelve in number, were performed upon dogs, with a view, mainly, it would seem, of ascertaining the best mode of sewing up wounds of this description, without going at all into the question of their mode of repair. Seven years after this, namely, in 1812, appeared the admirable treatise of Benjamin Travers, of London, entitled, *An Inquiry into the Process of Nature in Repairing Injuries of the Intestines*. His researches were more especially directed to the elucidation of penetrating wounds, and to the proper management of the bowel in strangulated hernia—topics discussed in a very able and scientific manner. In conducting these researches, the English surgeon availed himself of experiments upon dogs, and of the ample clinical opportunities afforded him at Guy's and St. Thomas's Hospitals. I need hardly add that Mr. Travers's essay was one of the most original and important contributions made to surgical science in the early part of the century. The work was not republished in this country, and did not, I think, excite much attention even on the other side of the Atlantic. For a knowledge of its valuable contents the surgeons of Europe and America were mainly indebted to that storehouse of surgical facts, Prof. Samuel Cooper's *Surgical Dictionary*, a work of world-wide celebrity.

Among the French surgeons who in the first third of the present century busied themselves in enlarging our knowledge of the treatment of wounds of the intestines by an appeal to experiments upon the inferior animals may be mentioned, with special commendation, the names of Jobert, Lembert, Gély, Amussat, and Choisy, on account of the peculiar forms of sutures respectively recommended by them.

Convinced that this department of surgery was susceptible of still further investigation, I commenced a series of experiments in 1841, which was continued, with occasional intermissions, until the end of 1843, when an account of them was published in the *Western Journal of Medicine and Surgery*, issued at Louisville, under the editorship of Drake, Yandell, and Colescott. A small edition was also issued in separate form, but as the printing office in which it had been stored away was soon after consumed by fire, few copies were saved. Hence the reason why such little notice has been taken of my labors. Indeed, the only account I have ever seen of them is comprised in the *Surgical History of the War*.

The object which I had in view in undertaking these researches was, first, to ascertain the process employed by nature in repairing wounds of the intestinal tube; and, secondly—and more particularly—to determine, if possible, the best methods of treatment. The experiments, upwards of seventy in number, were performed exclusively upon dogs, as the most eligible animals that could be selected for the purpose. The wound was generally made in the small bowel, not only because it is more readily accessible than the large, but because, when injured, it is more liable to give rise to extravasation of fecal matter, and also, possibly, to high inflammation.

Gunshot injuries of the bowels, so common during the War of the Rebellion, are more ably and fully discussed in the *Surgical History of the War* than in all other works put together, and what is true of wounds caused by firearms is equally true of other injuries of the intestinal canal. Dr. Otis spared no pains to embody in his chapter on this subject the latest information to be found in the magnificent medical library accessible to the Surgeon-General of the Army and his intelligent and laborious assistants, to whom the profession is so much indebted for our Army Medical Reports.

Wounds of the intestines may, like similar lesions in other structures, be incised, contused, lacerated, or punctured, the latter including those made by gunshot. Incised wounds are occasionally inflicted accidentally upon the bowel in hysterectomy and ovariotomy, and in operations performed for the relief of strangulated hernia. All injuries of this kind of the intestinal tube, whether single or multiple, simple or complicated, derive their chief importance from two sources—escape of fecal matter and peritoneal inflammation. The accompanying hemorrhage is generally a subordinate occurrence.

The manner in which wounds of the intestinal tube are repaired depends very much upon their character. Simple incised wounds, if properly treated, heal by union by the first intention, as similar wounds involving the skin, muscles, and other structures; that is, the effused plasma soon becomes organized and is transformed into cicatricial tissue. When the suture is carried through the mucous membrane the healing process is more tardy, and, if some of the stitches should give way prematurely, so as to allow the edges of the wound to gap, the union will be effected mainly through the agency of the serous coat. Granulations always form with difficulty, aud rarely afford much aid in filling up the breach. In nearly all of my experiments upon dogs, I noticed that the wounded bowel at the seat of the injury was speedily glued either to the omentum or to some adjacent coil of intestine, thereby forming, in most cases, an effectual barrier to fecal effusion. Conjecturally, we may assume that a similar occurrence obtains in a human subject. The ligatures, when the ends are cut close, are always discharged into the interior of the tube, the period at which this takes place varying with many circumstances from ten to fourteen days, as the ordinary average, to three or four weeks, as the extreme. Lacerated, ragged, contused, punctured, and gunshot wounds heal in the same manner as incised, but the process is more tardy and more liable to fail. When wounds, of whatever kind, are left to themselves, or to the unaided efforts of nature, the subjects of them either perish from their effects, as fecal effusion, peritonitis, hemorrhage, or septicæmia, or, if they recover, their safety is due to the adhesions which the injured portion of the tube contracts with the surrounding parts.

The diagnosis of wounds of the bowel is a matter of primary consideration, as upon its prompt determination the success of our treatment must mainly hinge. The possibility of this will, of course, mainly depend upon the situation in which the bowel is found at the time of the accident. If it has escaped

through the wall of the abdomen, it will generally be easy to find the injured part by the egress of some of its contents, as feces, mucus, or bile, or all these together; and so also when there is a discharge of some, or all, of these substances through the outer wound, although there be no protrusion of the intestine. The coast in both of these conditions is sufficently clear, so clear, indeed, that he who runs may read and accurately interpret. But it is altogether different when the abdomen has been pierced by a narrow instrument, as a knife or a dirk, or perforated by a bullet. In such an event the bowel does not protrude, and hence the true nature of the case must be solely a matter of conjecture. All that is positively certain in such event is that there is a wound in the wall of the abdomen. The surgeon, especially if called immediately or soon after the receipt of the injury, must be in doubt whether the weapon has entered the bowel or not. In reflecting upon the subject, he recalls the fact that a bullet, a rapier, a sword, or a ramrod has occasionally passed through the abdomen, and, perhaps, even emerged at the opposite side, without, in the slightest degree, interfering with any of its contents. The records of surgery furnish many such cases.

The two principal signs which must serve to guide us in these uncertain cases are tympanites and a discharge of blood by the anus. The occurrence of tympanites is unquestionably a symptom of great value. Jobert, who was the first to notice it, regards it as the most reliable of all the phenomena when there is no escape of feces, mucus, bile, or other fluid at the abdominal wound, and in this opinion the results of my personal observation fully coincide. The tympanites supervenes at various periods; sometimes almost immediately after the wound in the bowel has been received, and is then always of proportionate diagnostic value; at other times it supervenes very gradually, and in some cases, again, it does not make its appearance under twenty-four, thirty, or thirty-six hours. However this may be, it is always diffused, not circumscribed, and sometimes reaches an enormous height, the belly emitting a hollow, drum-like sound on percussion, and is then always very painful.

Although tympanites is generally present in lesions of this kind, there are cases in which it is entirely absent, as, for example, when the wound in the bowel amounts to a mere puncture, in which the opening is effectually closed by the protrusion of the mucous membrane, thereby preventing all escape of gas into the peritoneal cavity.

A discharge of blood by the anus I regard as a very valuable symptom of the existence of a wound in the bowel. It is especially valuable when it makes its appearance within a short time after the infliction of the external wound, and when it continues, more or less abundantly, for some days afterwards. As the blood is always intermixed with the contents of the bowels, it seldom comes away in a pure state, but is generally of a dark color, and of a grumous consistence.

No useful conclusions can be deduced from the shock and the pain which attend lesions of this character, since both vary greatly in different cases and in different circumstances, some persons suffering very little, while others, owing to the peculiarities of their nervous endowments, experience extreme distress.

In regard to probing wounds of this kind, the universal sentiment of the profession is opposed to it, on the ground that, while it can do no good, it would often be productive of great harm by disturbing the relation of parts, and thus endangering fecal effusion. I do not think, however, that this rule should apply to the mural wound. Here a probe, properly used, might at least afford useful information in regard to the direction and extent of the external injury.

In the treatment of wounds of the intestines two leading indications are scrupulously to be kept in view—the prevention of fecal effusion, and the occurrence of peritonitis. To secure the first, the only safeguard is efficient suturing of the wound. A case, it is true, occasionally recovers without any precaution of this kind, but this is owing to good luck rather than to good treatment. There was a time when surgeons, even of great distinction, considered the employment of sutures in wounds of the bowel utterly useless, if not absolutely detrimental. John Bell, a specious writer and an eloquent lecturer, who flourished in the early part of the century, and one of whose chief delights it was to walk roughshod over the teachings of his predecessors and contemporaries, declared that, if there be in all surgery a work of supererogation, it is the sewing up of a wounded gut. He taught that there was no peritoneal cavity, and that, consequently, there could be no fecal effusion in wounds of the bowel. The illustrious Scarpa, of Italy, for a long time the only great surgeon of that country, was equally prejudiced against the use of sutures; he considered them not only useless, but even dangerous. The practice in those days, and even at a much later period, was, in all lesions of this description, to pass a suture through the wound, and to bring out the ends at the external opening, a practice necessarily and inevitably followed by an artificial anus, and one by no means always, if indeed generally, free from the risk of fecal extravasation. The late Professor Gibson, of Philadelphia, writing in 1838, advocates a similar procedure; and Professor Syme, of Edinburgh, four years later, expressed himself to the same effect. These views may be regarded as a pretty correct expression of the teachings of surgeons in regard to this class of injuries forty-five years ago, notwithstanding the light that had been thrown upon them by Travers, Sir Astley Cooper, Lawrence, and others in England, and Jobert, Lambert, Gély, Choisy, and others in France.

The question here naturally arises, Should all wounds of the bowel, however small, be sutured? Upon this subject there was certainly till recently, if indeed there is not still, some diversity of opinion. Dionis, Palfin, Heister, and Sabatier state that enterrorhaphy is unnecessary when the wound does not exceed the diameter of a goose-quill or a penknife; and views of a similar nature are to be found in other writers, as Sharp, Richerand, Boyer, and

Jobert. On the other hand, there are surgeons who are opposed to the return of the bowel into the peritoneal cavity, however small the intestinal wound, without the employment of sutures, lest fecal extravasation should ensue. The great Benjamin Bell, of Edinburgh, writing near the close of the last century, holds, in the midst of the darkness that surrounded him, the following emphatic language: "However small a wound," he says, "of the intestine may be, it ought always to be secured with a ligature, for although it is alleged by some that we should rather trust to nature for the cure of a small opening than to insert a ligature, to me it appears that the opinion is by no means well founded, insomuch that I would not leave even the smallest opening that could admit either feces or chyle to pass, without stitching it up. Much danger may ensue from omitting it, and the hazard of the patient cannot be increased by the practice being adopted."

This advice of the sagacious Scotchman so clearly and emphatically enunciated nearly a century ago, is now the universal practice in all cases of wounds of the bowel, however diminutive, based as it is upon the well-ascertained fact that enterrorhaphy, when properly performed, is a harmless operation as compared with the risk of fecal extravasation and the consequent certainty of peritonitis.

It was with a view of testing this very matter, by determining how far even a small wound of the bowel might safely be entrusted to nature for a cure without the aid of sutures that I was induced to undertake the elaborate series of experiments alluded to in the opening part of this paper. These researches afforded abundant proof of the correctness of Mr. Bell's views; for, although I found that the wound, when it did not exceed two lines, or the sixth of an inch, was always closed by the intrusion of the mucous membrane, yet this did not always protect the parts from the effusion of fecal and other matter. Hence I have ever since laid the greatest stress, both as an author and as a public teacher, upon the importance of close suturing in all wounds of the intestines, however small. It is easy to conceive that even a very small wound, although completely occluded by the mucous coat at the moment of the restoration of the bowel, might, by the transit of stercoraceous matter, or by violent peristaltic action, become so unlocked as to admit readily of the escape of fluid or solid substance into the peritoneal cavity. Let it ever be borne in mind that the smallest possible quantity of fecal matter would be sufficient, certainly in many cases, if not in all, to light up fatal inflammation; and let this fact serve as the keynote to our practice in all cases of wounds of this description.

Judging from the results of my own observations, I have long been of the opinion that there are only two sutures that should ever be employed in sewing up a wounded bowel. These are the continued and interrupted, with the modifications of the latter by Lembert and Gély. As to Jobert's method, which consists in invaginating the ends of the bowel, when completely cut across, so as to place the two serous surfaces in immediate contact to facilitate their prompt union, the operation is not only extremely difficult, but very liable, even if successful, to be followed by more or less contraction of the tube at the seat of the injury, thereby interfering more or less seriously with the transmission of its contents.

The interrupted suture is, as a rule, preferable to the continued in all wounds of the bowel, whatever their extent or direction, whether they embrace the entire calibre of the tube or only a limited portion, and whether they are circular, oblique, or longitudinal. The operation executed with a long, slender sewing-needle armed with a thin but strong, well-waxed silk thread, is comparatively simple, affords ample security against fecal effusion, and is never followed by injurious contraction of the tube. The sutures should be placed not more than one line and a half, or the eighth of an inch, apart, and the ends, tied in a double knot, should be cut off close, so that, in time, the sutures may find their way into the bowel and be discharged along with its contents. I deem it very important that each suture should be fully one line from the edge of the wound, and that the needle should be passed deeply through the wall of the bowel instead of embracing its entire thickness, an arrangement which would almost inevitably be followed by more or less puckering, and by the consequent retardation of the cure. The operation of uniting the bowel where the division is complete, will be greatly facilitated if the first suture be inserted at the mesentery and the second immediately opposite.

The best, certainly the safest, ligature for suturing a wounded intestine is ordinary sewing-silk, well waxed, and inserted with a long, sharp sewing-needle. The carbolized catgut ligature is liable to give way prematurely, and should, therefore, be avoided.

In the modification of this suture by Lembert, the object is to invert the edges of the wound so as to bring the two serous surfaces in immediate and firm contact to establish, as it were, union by the first intention. Great advantage has been claimed for this form of suture, but this is not so apparent when it is remembered that, unless great care be taken in introducing it, it is liable to be followed by more or less contraction of the tube. In making this suture, the needle makes two dips on each side of the wound instead of one, as in the ordinary procedure.

"Gély's suture, which is merely a modification of that of Lembert's, is made with two needles inserted near the angle of the wound, about one line from its edge; they are then carried along the interior of the bowel, parallel with the wound, for the sixth of an inch, when they are brought out precisely at the same level, so as to appear again on the peritoneal surface. The threads are then crossed, the right needle being passed through the puncture made by the left, and conversely, when the ends are firmly tied and cut off close as in the ordinary operation. The number of sutures varies, of course, according to the extent of the cut. In this way the edges of the wound are thoroughly inverted, and consequently all danger of fecal effusion is pre-

vented; the coaptation, in fact, is so accurate as to conceal the ligatures."[1]

The treatment of wounds of the bowel by the continued suture has afforded good results in my experiments upon dogs. The chief objection to it is that it leaves the edges of the wound in an uneven, puckered condition, which interferes perhaps somewhat with rapid union. This, however, may be prevented in great degree, if not wholly, by the employment of a double thread after the fashion of the glover, although I do not consider this at all essential to success. Of the seventeen experiments performed with a single ligature, not one terminated fatally. The wounds in two of the cases were transverse, oblique in three, and longitudinal in twelve. The wound in one of the latter was six inches in length. The dog, a large, old one, was killed on the twentieth day, when every trace of suture had disappeared, with the full restoration of the calibre of the tube. I must not omit to state that in all these experiments the suture was passed through the fibrous tunic of the bowel, or, in other words, outside the mucous membrane. We have here then also a very valuable suture for sewing up wounds of the intestines, especially well adapted to the treatment of longitudinal and oblique wounds; not so well, I think, to the treatment of transverse ones as the interrupted.

The suturing of the wound having been completed, and any foreign substance that may be present removed, the bowel is restored to its natural situation, followed by the omentum, in the event of its prolapse. It is hardly necessary to say that the protruded structures should be treated in the most gentle manner; any wiping that may be required should be performed with the softest cloth, and all firmly adherent matter should be picked off with the forceps. Generally speaking, the best way of cleaning the parts is to make free use of the syringe, charged with warm water. The operation may be completed with a one to one thousand solution of corrosive sublimate. The return of the bowel will be materially facilitated by the use of a little olive oil. If any serious obstacle offer, it must be surmounted with the probe-pointed bistoury, or by puncture of the tube, if it depend upon the presence of gas. The wound in the wall of the abdomen should be closed in the same manner as in ovariotomy, the sutures being carried through the peritoneum so as to protect the parts effectually against hernial protrusion, a thing never to be lost sight of after such lesions.

The question arises here, What should be the conduct of the surgeon when the bowel is wounded, but not prolapsed, owing to the small size of the mural opening? I do not think that I can answer this question better to-day than I did forty years ago, when we knew comparatively little of abdominal surgery, and when the most visionary enthusiast could not have dreamed of half the triumphs that have since awaited it. The case in question is a suppositious one, and is thus stated: "A man, after having indulged in a hearty repast, receives a penetrating wound in the abdomen from the thrust of a dirk or knife; the bowel is pierced, or, it may be, nearly divided, and there is a copious discharge of fecal matter, both externally and into the peritoneal cavity, as is evinced, in the latter event, by the excruciating pain, the gastric oppression, and the collapsed condition of the sufferer. Here the most prompt and decisive measures must be resorted to, or the person will perish from peritoneal inflammation, with as much certainty as if his skull had been fractured and a portion of his brain had been let out. It will not do for the surgeon to fold his arms, and look upon the scene as an idle and disinterested spectator. Far otherwise; he has a duty to perform, and that duty consists in dilating the external wound, if it be not already sufficiently large, in hooking up the injured bowel, and in closing the solution of continuity with the requisite number of stitches, at the same time that the effused matter is carefully removed with tepid water and a soft sponge. All wiping must, of course, be carefully avoided, as this would add much to the risk of peritonitis.

"By the above procedure, which, under the circumstances pointed out, I should not hesitate to pursue, the patient is not placed in a worse condition than a female who has undergone the Cæsarean section, or a person whose abdomen has been ripped up in the first instance; recovery from both of which is not, as is well known, of unfrequent occurrence."[1]

It is a rule with all educated surgeons to do the work which they are called upon to perform in as complete and thorough a manner as possible, and nowhere is this precept of greater importance than in the treatment of wounds of the intestines. A case recently reported by Professor O. K. Roberts, of Louisville, Ky., will aid me in illustrating my meaning. A man was cut in the abdomen with a pocket-knife; the wound was three inches long; the bowel protruded, and was pierced at two points, one opening being of the size of a common lead-pencil, the other of a pea. The knife in its passage had stripped off the serous membrane over a space of one inch by one-quarter. There were two slits in the mesentery, each one inch in length; and the patient had lost much blood. The mural wound was closed by sutures which embraced only the skin and superficial fascia. None of the bleeding vessels had been secured, and active bleeding was still going on from three points in one of the wounds in the mesentery, the other being occupied by a clot. It was in this condition that the man was found by Dr. Roberts, shortly after his wounds had been dressed by another surgeon. Satisfied at a glance that the case had not been properly managed, Dr. Roberts reopened the mural wound, secured the bleeding vessels with carbolized catgut ligatures, stitched the openings in the gut more thoroughly, washed out the peritoneal cavity with hot carbolized water, and closed the abdominal wound with deep sutures, completing the dressing by inserting a drainage-

[1] Gross's Surgery, vol. ii. p. 613, Sixth Edition.

[1] An Experimental and Critical Inquiry into the Nature and Treatment of Wounds of the Intestines, p. 341, Louisville, 1843.

tube in the lower angle of the wound. Under this treatment with proper subsequent care the man made a rapid recovery. Had the dressing originally applied been allowed to remain, death would have been inevitable; either from hemorrhage, peritonitis, or peritonitis and septicæmia.[1] The case affords a happy exemplification of hasty, careless, slovenly surgery, on the one hand, and of thoughtful, wide-awake, scientific surgery on the other.

The therapeutics after all such lesions is sufficiently simple. The great point is to prevent peritonitis, or to combat it, if it takes place. The posture should be such as to relax thoroughly the abdominal muscles. The bowels should be locked up with opium to prevent peristaltic action, and nothing but iced water or pounded ice, aided, if there be much gastric distress, by a small allowance of dry champagne, should be permitted during the first three or four days. Oppression from gas should be relieved with injections of turpentine and asafœtida. Peritonitis should be met with leeching, followed by vesication with cantharidal collodion, and full doses of opium; venesection will be proper when the patient is young and robust. A laxative of castor oil, or of sulphate of magnesium, may be given at the end of five or six days, if there be marked suffering from tympanites. The urine should be drawn off during the first few days with the catheter.

I have, thus far, said nothing of gunshot wounds of the intestines. Such wounds are generally of a very serious nature, and are, therefore, liable to be followed by the worst consequences. In the first place, they are nearly always concealed wounds, from the fact that there is no prolapse of the bowel; secondly, such wounds are commonly multiple, as in one of my own cases, in which there were as many as eight perforations—two in the ileum, two in the jejunum, two in the duodenum, and two in the arch of the colon; thirdly, there is always more or less copious effusion of fecal matter; fourthly, great shock, to say nothing of hemorrhage, nearly always attends; and, lastly, most patients who survive the more immediate effects of such injuries are almost certain to succumb to peritonitis. The only rational treatment in such cases is to expose at once, or with the least possible delay, the peritoneal cavity, to stitch up, or excise, the wounded bowel, and, lastly, to clear away all extraneous matter. Excision of the tube is imperatively demanded when the wound is very large, severely contused, or very ragged. Nothing short of this would answer under such desperate circumstances; and even then no sensible surgeon would venture to pronounce a favorable prognosis.

It was my purpose, in connection with this paper, to offer some remarks on excision of the intestine in gangrene from strangulation in hernia; but it has already so far exceeded the limit originally assigned to it that I must confine myself to a few passing sentences.

The first operation that was ever performed for such an object occurred in the hands of Ramdohr, a German surgeon, who flourished in the early part of the last century. His patient was a woman, the subject of a strangulated femoral hernia, and, although fully two feet of her small intestine were removed, complete recovery ensued. This remarkable case remained for a long time a solitary illustration of the manner in which a man, inspired by genius and the gift of prevision, may project himself into the future far in advance of his plodding contemporaries. Towards the close of the last century, and the beginning of the present, operations of this kind became more frequent, chiefly through the labors and writings of Sir Benjamin Travers and Sir Astley Cooper, of London; Duverger, Boyer, and Lavielle, of France; and Schmidt and Dieffenbach, of Germany. In this country, the first case of the kind occurred in the practice of the late Dr. Charles Luzenberg, of New Orleans, in 1846. The case was one of strangulated inguinal hernia, in which that distinguished surgeon, on the basis of the recommendation contained in my monograph on wounds of the intestines, excised six inches of the ileum, and succeeded in curing his patient. Operations of this kind, dating from these humble and uncertain beginnings, now justly rank among the established resources of surgery. In an article published in THE MEDICAL NEWS for March 15, 1884, Prof. S. W. Gross refers to 67 cases of this kind, in the hands of different surgeons, nearly all European, of which 21 made complete recoveries, 2 escaped death with an artificial anus, and 44, or 65 per cent., perished. This remarkable mortality seems to have been due, not, as one might, *a priori*, have supposed, to peritonitis, but to the unsound condition of the bowel beyond the seat of the gangrene, a fact of great practical value, and one that should not be lost sight of in operations undertaken for this purpose.

TREATMENT OF SUBCHRONIC DIARRHŒA BY THE USE OF UNCOOKED, FULLY RIPE, FRESH FRUIT.

BY E. D. McDANIEL, A.M., M.D., LL.D.,
OF CAMDEN, ALABAMA.

IT is well known that many sufferers in Southern Europe annually await the season of the vintage as an expected cure for various disorders of health. This expectation is doubtless based upon experience and observation of the masses of the people, and it is also supported by the opinions of many eminent physicians. Dr. Warren Stone, the distinguished surgeon of New Orleans, once said that one of the greatest blessings that could come to the people of our country would be the general cultivation and use of subacid fruits.

Without some special knowledge of the effects of these subacid fruits, and of the maladies in which they are of service, we are liable to use them when we ought to avoid them, and to avoid them when we ought to use them. As a contribution to such special knowledge, I present here a history of two cases of subchronic diarrhœa, from which I took the hint for a number of cases that I have since treated and

have had treated by the dietetic use of fully ripe, but uncooked, fresh apples or cling-stone peaches. I mention apples and cling-stone peaches, because they were the fruits successfully employed by me. Perhaps some other, or many other fruits, may answer, but the *soft*- or free-stone peach, when tried by me, acted upon the bowels as a laxative, and did not do for the treatment of diarrhœa.

CASE I.—A man of sedentary occupation in Dallas County, Alabama, aged twenty-nine years, had an attack of dysentery (epidemic), which went off very reluctantly after a number of slight relapses, and left the man emaciated, debilitated, and with a digestion so impaired and bowels so irritable that various diets to which he resorted all failed to suit him, and all alike seemed to excite frequent, painful, but not copious or bloody, evacuations. This condition persisted for some weeks, when, about the early half of July, he went with a party of friends to Conecuh County, under the hope that a different water, a different air, and a difference of surroundings with rest and freedom from the cares and exertions of business, might be of value to him.

The first week passed in the new locality made no change in the symptoms, and the patient resolved to take nothing but tea for breakfast and supper and a saucer of soft peaches for dinner. Under this treatment the bowels became, at once, more active, and the actions more copious. Supper was then entirely abstained from, and the soft peaches with a little clarified sugar added were the only thing taken for dinner. The case made no improvement, and the patient, abstaining almost entirely from both food and water for a day or two, walked about in the groves surrounding the beautiful country residence where he was stopping, in very great discouragement and thoughtful as to what more he could do for himself. In one of these walks he climbed a fence to walk through an orchard adjoining and found many acres in peach trees, the trees being weighed down and the ground beneath them strewn with peaches, many of which were fully ripe, and many also passing into fermentation and decay. As the weather was dry and the sun hot, many of the cling-stone peaches, both on the trees and on the ground, had become extremely ripe and sweet, somewhat wilted in feel, and on one side discolored and toughened as if somewhat suncooked. These, beside having no sourness at all, but only a pleasant subacidity, had a peculiarly mild and mature sweetness, which was grateful but not cloying, and had acquired a flavor suggestive of brandy. The patient, not dreaming of benefit, but under the temptation of appetite and the recklessness of despondency, selected one or two of the most mellow of the cling stone peaches, and after thoroughly masticating them, swallowed the juice and pulp. He experienced no harm from the venture, and, thinking the matter over, determined to take nothing at all at the table, and to confine himself for a while to a cautious use of these almost dry-ripe cling-stone peaches. This he did, to the exclusion even of water itself. His bowels gave him no more trouble, and after about two weeks' restriction to the cling-stone peaches alone, he gradually returned to other articles of food, and, without a single dose of other curative, recovered his flesh and strength with all the other comforts of health.

CASE II.—In 1857, in Camden, Alabama, a man about thirty-five years of age had malarial trouble, for which he took sulphate of quinine very freely, and with satisfactory results, so far as the objects for which he took it were concerned, but the quinine seemed to irritate his bowels—at least these acted as though by some purgative every time he resorted to the free use of quinine. The result was that from about an hour before dawn until about ten o'clock A.M., every day, he would have from four to ten painful evacuations, not copious, or serous, or very exhausting, but very annoying on account of the great pain. This resided in the descending colon and rectum, paramountly in the sigmoid flexures and vicinity. The trouble resisted opiates, opiates with salines combined, bismuth, vegetable astringents, and such other modes of treatment as are most frequently productive of good in such cases. The most stringent rules of diet were most self-denyingly submitted to, but days ran into weeks, and weeks were running towards months, with no satisfactory improvement of condition, when one day the patient, hungering and thirsting and low-spirited, passed along the sidewalk by a window that was piled up with blushing western apples, whose ripe fragrance perfumed the neighboring air for some distance around. He resisted the temptation and passed on, under the impression that the apples would be bad for his case. Day after day he suffered the same way and passed the same window and successfully resisted the same temptation. At length, finding no change for the better, from regimen or medicine, either or both, and being on a rigid fast and in a half-desperate mood, he halted at the store, procured three of the finest and ripest of the apples, and then went on. Two of these apples he put into his pocket to await the effect of the other, of which he scraped a part with his knife and swallowed the scrapings, both juice and pulp. This partially allayed his hunger and partially quenched his thirst, and as his bowels suffered no harm, he took the remainder of the first apple as his exclusive food and drink for the rest of that day. The next morning brought no pain with it, and no action occurred from the bowels. The two remaining apples were used in the same way as the first, and constituted the sole food and drink of the forenoon of the following day. A half-dozen apples were taken as the food and drink of the third day of the treatment, and for a week or two nothing at all but mellow, choice apples, thoroughly masticated, were taken. There was no more pain or looseness of the bowels, and the convalescence was uninterrupted and complete.

These two cases, thus given at length, render it unnecessary to furnish details or even abstracts of many other cases of subchronic diarrhœa similarly and successfully treated; and, regarding them as fairly typical, I urge the importance of thoroughly ripe subacid fruits, not only as a remedy for similar troubles among the residents of tropical and subtropical regions, but also as an important factor

in diet in health, conducive to the prevention of such maladies by the correction of any scorbutic tendency in blood or tissue which may underlie these and other like maladies.

MEDICAL PROGRESS.

THE ETIOLOGY OF JEQUIRITY OPHTHALMIA.—As is well known, says E. KLEIN, of London, Sattler and De Wecker have stated that infusion of jequirity causes ophthalmia, by the presence of a bacillus and its spores. He has recently made observations on this subject which lead him to contradict this statement. The jequirity seed were deprived of the perisperm, powdered, and then an infusion placed in a retort sterilized by heat, containing boiled distilled water, and sealed with sterilized cotton. This was a one-half per cent. solution, as used by Sattler. The infusion was made with lukewarm water. After half an hour the infusion was filtered into a sterilized flask through a clean, heated filter. From this filtrate a small quantity was removed by means of a capillary tube, and four flasks, containing sterilized peptone-solution, were inoculated. By means of the same capillary tube the conjunctivæ of four rabbits were inoculated. The inoculated flasks were placed in ovens and kept at a temperature of 35° C. After twenty-four hours, the rabbits showed the typical intense ophthalmia, while the flasks were perfectly clear, there being no trace of cloudiness; furthermore, the inoculation of new cultures and microscopic examination showed no microorganisms of any kind.

A second and third series of experiments gave the same results, and Klein says that he is forced to the conclusions that Sattler's statement that the jequirity infusion owes its action to the presence of a bacillus is untenable; that Sattler must have used much stronger infusions than he; that he used infusions which had been kept for several days; and that he inoculated the eyes with bacilli when these old infusions were used.—*Centralbl. f. d. med. Wissensch.*, February 23, and March 15, 1884.

NAPHTHALIN IN THE TREATMENT OF WOUNDS.—In the *Vratch*, 1882, No. 39, and 1883, No. 2, DR. P. T. DIAKONOFF, of Orel Zemsky Hospital, publishes eighty cases of wounds, abscess-cavities, and ulcers, in which he used naphthalin as an antiseptic, in the form of medicated wool, gauze, or jute, or crystals, powder, ointment, or rods made of equal parts of the drug and gelatine or cacao butter. The results obtained by the author are decidedly favorable to the new antiseptic. The advantages claimed by him for naphthalin are its cheapness, harmlessness, and the ease of application. Of its drawbacks he mentions only two: 1. Naphthalin dressing in some cases gives rise to severe pain. 2. It does not prevent the appearance of erysipelas. The author never saw any formation of crusts, or occurrence of eczema, and other signs of local irritation, or hemorrhage, after the use of naphthalin, of which Drs. Hoeftmann (*Centralbl. für Chirurgie*, 1882, No. 72) and Hager (*Ibid.*, No. 50) complain.

DR. V. LINDENBAUM, of Jaroslavl (*Vratch*, 1883, No. 17), has used naphthalin in nearly fifty cases of frostbite, the toes and fingers being mostly the parts affected. In many cases extensive, freely suppurating, sloughing ulcers were present. The method after which the cases were treated was simple. First, the affected parts were washed with a carbolic solution (3 to 5 per cent.); then they were covered with a thin layer of pure crystallized naphthalin (*naphthalinum albissimum*), over which a large piece of soft carbolic gauze was laid; then a few cakes of resinized tow followed; lastly, a thin sheet of waxed paper was placed, and the whole fixed and compressed by a starched gauze bandage, or, for the sake of cheapness, by narrow strips of adhesive plaster. The dressing was changed, as a rule, every seven or ten days, and only in cases of profuse suppuration every four days. Healing generally progressed very rapidly. The author never saw any untoward symptoms, except slight pricking pain during the first two or three hours after powdering, and slight hemorrhages from granulations. Wounds ran their course without any rise of temperature.—*London Medical Record*, March, 1884.

SIMULTANEOUS LIGATURE OF THE SUBCLAVIAN AND COMMON CAROTID ARTERIES FOR INNOMINATE ANEURISM; RECOVERY.—DR. JULIUS ROSENSTERN reports the case of a woman, æt. 42 years, who, about two and a half years ago, began to experience pains in the upper part of the chest, and extending into both arms. In July, 1883, a pulsating swelling was noticed on the right side of her neck, and has since increased. The symptoms were those of aneurism of the innominate artery.

On November 26th the right common carotid and subclavian arteries were ligated, two ligatures being placed upon each. The wounds were irrigated with a four per cent. solution of carbolic acid, filled with iodoform gauze, then sewed up with the exception of a small opening for the passage of the ligatures and an iodoformized drainage-tube. The whole was covered with an iodoform wadding bandage, the head drawn over to the right side with triangular cloths, and the right arm firmly bandaged to the thorax. The bed was elevated at the foot to facilitate drainage and guard against a congestive abscess in the mediastinum.

The first bandage was changed on the seventh day after the operation, the iodoform gauze removed, the wounds iodoformized and compressed with iodoform wadding bandage. The sutures were removed on the fourteenth day. The edges had united by first intention, with the exception of the space occupied by the drainage-tubes, which were also taken out at the same time. The temperature only rose once to 102°. The pulse was at first 100, and very strong, but gradually came down to 80. One ligature of the carotid came away on December 24th, the other eight days later. The ligatures of the subclavian came away toward the end of February. The right radial pulse reappeared on January 2d, but is still very much weaker than on the other side. The pulse in the right temporal artery cannot yet be felt.

On the 1st of January she left the bed for the first time, and went home on the 8th. Since the day after the operation the pains and difficulty of breathing have not returned. The tumor, though considerably diminished, has not entirely disappeared.—*Pacific Med. and Surg. Journ.*, March, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 3, 1884.

THE MODERN CURE OF HYDROCELE.

In the *Wiener medizinische Wochenschrift*, Nos. 1, 2, 3, and 4, 1884, may be found a contribution to "The Final Results of Radical Operations for Hydrocele," from the pen of DR. OTTO WEISS, which is mainly interesting from the fact that it gives the experience of Billroth with the injection of iodine in 166 cases, in 5 of which suppuration, demanding free incision, ensued, and in 6 the affection was known to have recurred. In addition to this paper, JULLIARD, of Geneva, describes his modified operation of antiseptic incision of the sac in the *Revue de Chirurgie*, No. 2, 1884. From these contributions, as well as from information derived from public and private sources in our possession, we have gleaned some facts which will doubtless prove of interest to our readers, as they throw new light upon the relative merits and disadvantages of the most popular methods of treating hydrocele.

Of the curative measures, the one that is most frequently resorted to is the injection of tincture of iodine, either pure or diluted with an equal weight of water, or in the form of Lugol's solution. Unless we greatly mistake, the profession is inclined to regard this operation as being absolutely safe, and certain in its results, despite the fact that there are not a few isolated examples of death following its employment, to say nothing of the occurrence of shock, severe pain, undue inflammation, and gangrene of the scrotum, even in the hands of experienced surgeons. That the failures have been underestimated, and that some of its risks are not sufficiently well appreciated, becomes apparent from an analysis of 523 cases which we have collated from the practice of Billroth, Esmarch, Kocher, Volkmann, Krabbel, Jacobson, Osborn, and Abbe. Of the entire number, the disease recurred in 44, or 8.4 per cent., while acute suppuration supervened in 5, or 0.95 per cent.—2 after the use of equal parts of the agent and water, and 3 after the injection of the compound tincture. It may be remarked that the failures are as common after the injection of one solution as another, and that about three weeks are required to effect a cure.

Within the past decade, the treatment of hydrocele by antiseptic incision has been much practised, particularly in Germany. In this operation, to which the name of Volkmann is attached, the scrotal tissues are freely divided, under the spray, down to the vaginal tunic; bleeding vessels are secured; the sac is opened by an incision of similar length, and syringed out with a three per cent. solution of carbolic acid, when the edges of the serous membrane and external wound are united with catgut sutures, a short drainage-tube being inserted at the most dependent portion of the cut, and the parts firmly occluded and compressed by carbolized gauze and bandages.

The advocates of this method declare that it is absolutely safe, certain, and rarely attended with surgical fever; but their positive statements are not sustained by an examination of 254 cases, recorded by Volkmann, Kuester, Weir, Englisch, Albert, Lister, and Jacobson, Of this number, not only did the fluid reaccumulate in 3, or 1.18 per cent., but 2 patients, or 0.79 per cent., died, respectively, of septicæmia and pyæmia. In addition to these evils, carbolic acid erythema, abscess in the connective tissue, and partial sloughing of the edges of the wound have not infrequently been observed, and orchitis has now and then been met with. Although a cure is secured in about ten days, the parts remain tender, hard, and swollen for about three weeks in the majority of cases, so that the subject really does not move about with comfort for one month. It should be noted that the advocates of the operation have referred the tenderness and tumefaction to the plastic infiltration of the vaginal tunic, through which the obliteration of the cavity is secured, while its opponents have ascribed it to orchitis and epididymitis. That neither of these views is correct, is shown by a case recorded by Kraske, in the *Centralblatt für Chirurgie*, No. 47, 1881, in which death ensued on the tenth day from intercurrent pneumonia. There was no lesion whatever of the organs referred to; but the swelling was due to a clot of blood undergoing connective-tissue substitution, or so-called organization, at its periphery. The result of this examination led, in the succeeding thirty-one cases in Volkmann's clinic, to the careful securing of all vessels, so that the tumefaction was reduced to a minimum in the ma-

jority and was entirely absent in a few. In a second case of death from internal strangulation of the intestine on the tenth day, Julliard was enabled to confirm the statement of Kraske.

The operation of Volkmann has been variously modified, with the view to dispense with a large incision and shorten the duration of the treatment. Thus, Volkmann himself, Reyher, Trendelenburg, and Weir made a small puncture or incision, washed out the cavity with a carbolic acid solution, and inserted a small drainage-tube. The disadvantage of this procedure is that the small opening may close after the removal of the drain, before firm adhesions have taken place, through which there will be danger of recurrence, as happened in 1 of the 19 cases in which it has been resorted to. Jacobson, in 3 successful cases, opened the sac by a cut about two inches long, and excited the formation of granulations by inserting a narrow strip of gauze soaked in carbolized oil. Finally, Julliard incises the sac freely; removes with the scissors or spoon any pathological products which may exist on the vaginal tunic, the testicle, or the epididymis; ties all bleeding vessels; resects the vaginal tunic, so as to leave enough to cover the testicle and the cord; unites the edges of the tunic with catgut sutures; inserts a rubber drainage-tube in the lowermost portion of the external wound, and closes the latter with catgut. Of his 54 cases, there was recurrence in 1, which was probably due to the irritation produced by the decalcified bone drain, which was found, at the end of fifteen months, to have undergone no change whatever, and 1 patient died of internal strangulation in ten days. Hence, of 330 examples of antiseptic incision of the sac, there were 2 deaths, a mortality of 0.6 per cent., and 5 recurrences, or a percentage of 1.5. These disadvantages and risks are offset by the short time required to effect a cure, although the parts remain swollen and tender for about three weeks.

Antiseptic incision has materially increased our knowledge of the changes which occur in the sac and its contained organs. Thus, in the 54 cases recorded by Julliard, and in 69 reported by Genzmer, from Volkmann's clinic, in the *Sammlung klinischer Vorträge*, No. 135, or in a total of 123, cysts were found on the vaginal tunic, the testicle, or the epididymis in 43, the testicle and epididymis were enlarged in 23, the vaginal tunic was thickened in 54, false membranes were present in 26, and free or attached foreign bodies were met with in 3. These abnormal products are regarded by some teachers as being the cause of recurrence after the treatment by injection; but we are of the opinion that they indicate merely that disturbances in the secretory apparatus of the male genital organs occasion hydrocele as well as the lesion referred to.

For the past three years, Dr. Levis has resorted to the injection of from thirty to sixty grains of the deliquesced crystals of carbolic acid into the sac, but with what results we are not informed, save in the general statement that the treatment has been almost uniformly successful. The method is certainly painless, is not productive of shock, involves no trouble, and is speedily carried out. The patient need not keep his bed longer than a few days, but the swelling does not disappear, on an average, before the expiration of one month. Of 82 cases, in the hands of Weir and Abbe, suppuration occurred in 3, in one of which the sac sloughed; but the amount of the agent used—from two to three drachms—was too large. In a fourth case, the sac rapidly filled with bloody serum, which had to be let out. These drawbacks may be met with even when a small quantity of the remedy is employed. Thus, in two cases under our own care, the injection of one drachm was followed by a large effusion of blood into the sac, an accident which is doubtless due to the separation of the endothelium and the rupture of the underlying vessels of the vascular connective tissue. Suppuration ensued in a case recently treated with twelve minims by Abbe, and in one, now in the Jefferson Medical College Hospital, from the injection of half a drachm. No death has as yet been recorded; nor has recurrence or carbolic acid absorption been observed.

An analysis of the facts contained in the preceding paragraphs warrants the conclusion that antiseptic incision of the sac is too severe for ordinary cases, and that it should be reserved for those in which the vaginal tunic is much thickened, and for examples of recurrence after the employment of simpler methods. Although the injection of from thirty to sixty grains of liquefied carbolic acid, as a curative measure, has not as yet been sufficiently tested, we think that we are justified in predicting that it will prove to be the simplest, safest, and least inconvenient of all the measures heretofore employed for the cure of the very common affection under consideration.

THE STAINING OF KOCH'S BACILLI.

So much has been written and printed since Koch's original publication, upon the treatment of tubercle-bacilli with a view to their better and easier demonstration, that a systematic article by FRAENKEL, published in full in the *Berliner klin. Wochenschrift* for March 31, will be welcomed by physicians, especially as the methods are intended to be employed in the office rather than in laboratories.

In general, it may be said of the bacillus tuberculosis that it imbibes only certain aniline coloring matters; that a certain period of exposure is necessary; and that it must be treated by certain additional fluids to secure the most distinct demonstrations.

After a comparative trial of twenty aniline colors, Fränkel concludes, with other investigators, that the best are, undoubtedly, methyl-violet and fuchsin. Both of these are hydrochloric acid combinations, and both stain animal fibres more easily than vegetable. As to the time required for staining, ten minutes are necessary at the temperature of the room, although a much shorter time suffices in the warm box, while Rindfleisch has also shown that by warming the fluid the staining may be made instantaneously.

With the added fluids, Fränkel found the aniline water, as first suggested by Ehrlich, to give the best results, although equally good results were obtained with toludin water, an analogous substance which is always found to accompany the commercial aniline as an impurity. A durable fluid is composed of 93 c.c. of water, 3 c.c. of aniline oil, and 6 c.c. of alcohol. In this aniline water the coloring matters may be dissolved, but it is better to have on hand alcoholic solutions of fuchsin and methyl-violet, and before using to add, by means of a dropper, as Ehrlich originally suggested, as much of the solution of coloring matter as will produce a decided opalescence in the fluid. Five cubic centimetres of aniline water are heated to boiling in a test-tube, poured into a watch-glass, and the concentrated solution of coloring matter added. Upon this the covering-glass, on which the sputum is smeared, and dried by passing it a few times over the flame of an alcohol lamp, is floated for from two to five minutes.

In order to demonstrate the bacillus more distinctly, acids, alcohol, and watery solutions of other aniline colors are used, either to decolorize the other elements of the sputum, cells, nuclei, other fungi, or foreign substances, or so to stain them by these colors as to put them in contrast with the stained bacilli. For this purpose Ehrlich uses nitric acid diluted three times; Petri, glacial acetic acid; Rindfleisch, feebly acidulated alcohol; and Koch, in the beginning, vesuvin-solution.

Fränkel regards it as especially important to re-stain the decolorized preparation, thereby eliminating all possibility of mistake. For this purpose he has recently used a mixture of 50 parts of alcohol, 30 of water, and 20 of nitric acid, which is saturated with ethyline-blue and then filtered. Into some of this fluid the preparation is carried directly from the first color solution, and in this way the decolorization and second staining are at once accomplished, an immersion of one minute sufficing. The sputum on the cover-glass is then washed in water or in 50 per cent. of alcohol acidulated with one per cent. of acetic acid, and well dried by first compressing between filtering paper, and then quickly passing through a flame. In this way, says Fränkel, a preparation can be completely made and doubly stained in four minutes.

Baumgarten's method of demonstrating the bacillus unstained is less satisfactory. By Gibbes's method of staining the bacilli red and the background blue, by a single fluid, Fränkel thinks fewer bacilli are brought out than by the one detailed.

As to the use of an immersion system and Abbe's illuminator, Fränkel says much time is saved by them, but that with a good Hartnack No. 7, or any corresponding power, and ordinary illumination, the bacilli are easily recognized.

BATTEY'S OPERATION.

THIS operation was recently discussed in the Société de Chirurgie of Paris. POZZI narrated the case of a patient who had a tumor of the left ovary as large as an adult head, and who was bed-ridden for five years. She had left hemianæsthesia and hemiparesis; the left eye was amaurotic, and she had erotic nervous attacks each night. Removal of the tumor effected a perfect cure. In the discussion of the subject, TERRIER took the ground that Battey's operation was indicated in cases of obstinate hysteria if the ovaries were painful, at the same time mentioning that very grave hysteria had developed in one case upon whom he had performed ovariotomy, the subject having previously been quite free from the disorder. GILLETTE, on the other hand, thought Battey's operation a bad one, and not founded upon reason. Nevertheless, the general tone of the discussion was favorable to the operation—a just compliment thus paid our distinguished countryman by those who make no haste to discover merit on this side of the ocean, or, indeed, outside of France.

EXTIRPATION OF THE LUNG.

AMONG the novel experiments recently tried in Italy, the extirpation of the whole, or a part, of the lung seems the most remarkable. Fifty-seven animals—sheep, dogs, cats, and others were the subjects—had an entire lung extirpated, and thirty-five recovered. In twenty-three cases the right lung was removed, and twelve recovered; the left lung was taken away in thirty-four, and there were eighteen recoveries. There were three cases of removal of the upper part of a lung, and one each of removal of the middle and of the lower lobe; all recovered. It is very doubtful if these experiments will ever be imitated, on an extended scale, in human beings. Professor KRÖNLEIN, of Zürich, however, in a case of recurring round-celled sarcoma of the sixth rib, recorded in the *Berliner klinische Wochens.*, of March 3, 1884, not only removed a large portion of the wall of the thorax, including the costal pleura, but also resected a portion of the lung, which was the seat of a secondary sarcomatous mass. The insignificant bleeding from the lung stopped after bringing the edges of the wound together with catgut sutures. In one month the patient was discharged cured.

SOCIETY PROCEEDINGS.

THE MEDICAL ASSOCIATION OF GEORGIA.

Thirty-fifth Annual Session, held at Macon, April 16, 17, and 18, 1884.

(Specially reported for THE MEDICAL NEWS.)

THE thirty-fifth annual session of the Medical Association of Georgia convened in the city of Macon April 16, and continued in session three days.

FIRST DAY.

The Association was called to order by the retiring PRESIDENT, DR. K. P. MOORE, of Macon. After prayer by Rev. A. J. Battle, D.D., Dr. Wm. F. Holt, of Macon, in a neat address, welcomed the Association to the city. This address was responded to by Dr. L. B. Alexander, of Forsyth. The PRESIDENT-ELECT, DR. A. W. CALHOUN, of Atlanta, was then introduced, and delivered

THE ANNUAL ADDRESS.

He said: My subject—*School Hygiene in Relation to its Influence upon the Vision of Children*, or school sanitation—does not express the full scope of this discourse, but is a faint outline of what I shall have to say to you in the time allotted to me.

The medical aspects of life are deservedly attracting more and more the attention of doctors in every land where education and civilization have made much progress. The researches of one investigator developed the fact that out of more than 2300 infants examined by him, only 122 possessed abnormal peculiarities of any kind, and from this fact drew the conclusion that, when they start to school, children, as a rule, are physically sound. That deformities of one organ or another, simple or serious, do exist amongst school-children, admits of no argument, and many of these may be reasonably attributed to the influences surrounding a child during its life in the school-room. The various parts of the organism of youth are easily disarranged, and if the cause operates continuously, the disarrangement is liable to become permanent.

Before the child even sees the inside of a school-room, he learns many useful things—often more than he does in the next succeeding five years, and yet this learning does not injure his eyes. It is a fact that children, at the time of entering school, are free from that common affection, near-sightedness, but almost immediately thereafter the disease begins to show itself. This is conclusive evidence that the fault, to a great degree, at least, lies in the school.

For many years, deterioration of the eyes among pupils in public and private schools has been a topic of complaint and investigation both in this country and the older nations of the world. This impairment of sight, this deterioration of the eye, is principally the immediate results of myopia, or near-sightedness, which, in its turn, is caused by defective modes of education and their hurtful surroundings.

After entering minutely into myopia and its causes, Dr. Calhoun said in reference to its treatment: Prevention is the sole resource at our command; restoration is impossible; and in order that preventive measures may be seasonably adopted, it is first necessary that the profession and the public should become alive to the fact that in a large number of cases myopia is one of the gravest affections of the eye, capable of limitation by constant care during childhood and youth; but, if not thus limited, likely to be a source of future disability and misery, and to be handed down as an onerous inheritance to children. After referring to the fact that the disease myopia was unknown in the negro in the South in *ante-bellum* days, and showing from statistics that education had produced the disease in a great number of them recently, he closed with the following sound words of advice: Fewer hours of study, and more rational methods of teaching; less cramming of mere memory, and more healthy development of the intellect, will make brighter, healthier, and more intelligent students, who will develop into stronger, hardier, and more energetic men and women. For such as these the practical affairs of life offer many and varied fields of usefulness, while for the sallow-faced, narrow-chested, weak-eyed bookworm there is no room in a busy world.

DR. JAMES P. LOGAN, of Atlanta, Chairman of the

COMMITTEE ON AN INEBRIATE ASYLUM,

reported that every effort had been made to have the legislature pass an act providing funds for the establishment of such an institution, but without avail. He said he was satisfied that it was impossible to induce them to do anything in the matter, and asked that the committee be discharged. The request was granted.

DR. H. V. M. MILLER, Chairman of the

COMMITTEE ON EXPERT TESTIMONY,

said it was difficult to get the legislature to understand that a law providing proper compensation for medical experts was not "class legislation." He had proposed and had presented to that body a bill, but could get no one to advocate it. He suggested that the committee be continued, and that a bill be proposed providing for the payment of all experts: not only medical experts, but experts of every class called into court to testify, and that they be compensated as the judge trying the cause might determine. On motion, the committee was continued.

DR. MILLER, Chairman of the

COMMITTEE ON ANATOMICAL MATERIAL,

reported that a bill had been prepared and presented to the legislature and passed both houses, but was vetoed by the Governor after the adjournment of the legislature. The Governor had never published any reasons for this veto, but he had been informed that it was done on account of the short time allowed in which strangers dying in the State should be held before being delivered to the medical colleges. The bill provided for twenty-four hours only. He further stated that he thought with that objectionable feature of the bill removed, it might yet become a law. The committee was continued, and instructed to use every effort to obtain a law providing dissecting material for the colleges.

DR. EUGENE FOSTER, of Augusta, Chairman of

THE COMMITTEE ON NECROLOGY,

presented touching and beautiful memorial tributes on the lives and characters of Drs. E. H. W. Hunter, of

Louisville, Sterling Eve, of Augusta, J. M. Carlton, of Athens, Alexander Means, of Oxford, and L. D. Ford, of Augusta. The tribute to Dr. Ford was specially feeling and earnest, and was received with the most profound attention and reverence by the Association. Dr. Ford was the first President of the Association, he having been elected in 1849, at the organization.

THE COMMITTEE ON PRIZE ESSAYS

in their report stated that a number of essays had been submitted, but none was found worthy of a prize. The committee was continued.

Reports of sections from the several congressional districts were then secured.

SECOND DAY.

The Association was called to order by the President, Dr. A. W. Calhoun, at 10 o'clock A.M.

REPORTS.

The annual reports of the Treasurer and Secretary were read. They showed the finances of the Association to be in a good condition.

Under the call for voluntary contributions, a large number of papers were read by title, to be subsequently called up and read at the pleasure of the Association.

Only a few of these papers were read; they were all referred to the Committee on Publication, and will, no doubt, appear in the *Transactions* of the Association.

THIRD DAY.

The Association was called to order at 10 o'clock A.M. The entire morning session was taken up with the reading of voluntary contributions reported by title the previous day. Two of these papers deserve special notice, the one on *Consumption* by Dr. Miller, and the one on *Explanation of the Pathology and Therapeutics of the Nerve-centres*, by Dr. Gaston.

THE PRESIDENT appointed Dr. Jas. B. Baird, of Atlanta, *Orator* for the next year. He also announced the following

DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION:

Drs. Eugene Foster, H. F. Campbell, A. G. Whitehead, Jas. P. Logan, G. W. Mulligan, H. McHatton, B. R. Daston, De S. Ford, W. H. Doughty, Sr., W. F. Westmoreland, V. H. Taliaferro, W. O'Daniel, K. P. Moore, A. J. Logan, C. D. Smith, T. O. Powell, R. J. Nunn, T. J. Charlton, Robt. Battey, W. B. Wells, John Gerdine, E. Fitzgerald, M. G. Hatch, W. P. Nicolson, P. L. Hilsman, J. C. Solomon, Jas. A. Gray, S. B. Hawkins, G. G. Crawford, T. M. McIntosh, E. C. Goodrich, T. R. Wright, C. H. Hall, and A. W. Calhoun.

On motion, the President's name was added.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Eugene Foster, M.D., of Augusta.

Vice-Presidents.—Drs. J. B. Roberts, of Sandersville; and W. D. Bozzell, of Atlanta.

Secretary.—Dr. James A. Gray, of Atlanta.

Treasurer.—Dr. E. C. Goodrich, of Augusta.

The next meeting will be held in Savannah, on the third Wednesday in April, 1885.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

Eighty-sixth Annual Meeting, held in Baltimore, April 22, 23, 24, and 25, 1884.

(Specially reported for THE MEDICAL NEWS.)

THURSDAY, APRIL 24—THIRD DAY.

DR. J. W. CHAMBERS read a report of

FOUR CASES OF ABSCESS OF THE BRAIN.

In the first two cases, the abscesses were caused by external injuries; the patients died forty-six and thirty-one days, respectively, after the accidents. These cases, and especially the second, were interesting from the fact that in neither of them was there any evidence at the autopsy of depression or fissuring in the skulls—apparently the lesion was the result of a necrotic periostitis following contusion of the bone at the point against which the missile impinged. Dr. Chambers said that he had searched all the literature accessible to him without finding a similar injury to the bone recorded. It seemed to him impossible that a contusion (rupture of capillaries, and, possibly, laceration of brain substance) could be produced in the white matter of the brain without a similar injury to the cortical substance, but he suggested that probably the contusion in the cortical substance might be entirely recovered from, whilst in the white substance the comparative paucity of vascular distribution renders the repair of such an injury much more difficult. The two remaining cases were not caused by any external injury; one was due to embolism, and the other was probably idiopathic.

DR. JOSEPH T. SMITH then read a paper entitled

THE PAST YEAR IN PATHOLOGY,

in which he entered very fully into the recent developments, taking up specially the germ theory. He dwelt largely upon the results of the work of the French and of the German Cholera Commissions—results which, though by no means all that is needed on the subject, have gone far toward the desired goal. Dr. Smith discussed the bacillus of tuberculosis, and entered somewhat into detail on the subject of the various controversies now being carried on on the subject, quoting from authorities on the opposing sides. He then gave the results of the investigations carried on at the Brompton Hospital, London. He concluded his remarks in this connection as follows: "It is more than probable, then, that the bacillus will be shown to be a veritable microörganism; that it will be of value as a diagnostic, and possibly as a prognostic agent; but, while it may be active in the production of phthisis, something more is required, and that not it alone is responsible for phthisis" (referring to individual susceptibility).

DR. FRANK DONALDSON then read a paper on

THE INFLUENCE OF LUNG RETRACTILITY IN PLEURISY AND PNEUMOTHORAX.

He said that it is strange how observers have neglected to apply the knowledge gained by physiological research of the retractile force of the lungs to the investigation of the pathological conditions of the chest. This neglect has had a very considerable effect in retarding our progress in the thorough study of the diseases of the

chest. He proceeded in detail to consider the various contributions towards a correct estimate of the subject treated of in his paper by Marcy, Hutchinson, Hyde, Salter, Powell, and Le Gros Clarke, who had all, in some degree, prepared the way for the work of Dr. W. H. Stone, of London, who in 1877 reported his experiments upon sheep, from which he concluded that the retractile power of the lung was equal to four or five inches of water. He also showed that even when the effusion was considerable in the pleural cavity, the lung still possessed contractile power enough to support two inches of water, so that to evacuate the fluid it was necessary to use external suction sufficient to overcome this lung traction. Dr. Garland, of Boston, a few months after this, gave a great impetus to the study of the dynamics of the chest in his work on *Pneumo-dynamics*. Before 1843 it was thought almost universally that the effused pleuritic fluid obeyed the law of gravity as in open vessels or in a vacuum, and hence it was assumed that the fluid maintained a horizontal level. The distinction between impaired resonance (dulness) and flatness had not yet been recognized. M. Damoissan called attention to the fact that the line of dulness when the patient is erect does not assume a horizontal line, but one more or less following the curve of a parabola.

In 1874–1876 Dr. Calvin Ellis described the upper line of the effused fluid as beginning, with medium effusion, relatively low down in the back, passing outward from the vertebral column and turning upward and proceeding obliquely across the back to the axillary region, where it reaches the highest point. Thence it advances in a straight line, but with slight descent, to the sternum. This is the Ellis or S curve. When the fluid occupies most of the chest up to the second rib, the retractile power of the lung is lost, and the fluid will approach the horizontal line. This S curve Dr. Donaldson and others have confirmed by their own observation.

Dr. Donaldson then considered the influence of the retractile lung power in the production of displacements of the adjacent organs, heart, etc., displacement of lung diaphragm and intercostal spaces of liver, spleen, and stomach, and in the production of pneumothorax.

He concludes that lung retractility is not only a powerful physiological force in respiration, but that it also produces modifications of a decided character in diseases of the chest. The practical value of these facts consists in the aid they give us in the differential diagnosis of pleurisy and pneumothorax, the assistance they afford us in measuring the quantity of fluid in the pleural cavity, and the indications they furnish us as to the advisability of resorting to thoracentesis.

PROF. G. STANLEY HALL, of the Johns Hopkins University, then delivered an address on

LOCALIZATION AND RECENT PHYSIOLOGY OF THE BRAIN.

Among the results made probable by recent methods of study are the continuity of the pyramidal fibres of the cord to the cortex through the inner capsule, without the interruption formerly supposed, in the cells of the large basal ganglia. These tracts decussate only in part, and are the tracts, at least, for the arms of volitional motor innervation. The cerebellum, whatever other function it may have, appears to be very largely a commissure between the hemispheres, particularly between the "latent" frontal and occipital regions—the projection system of the "psychic zones" lying between these. Its very intimate connection with the red nucleus of the olivary bodies, and a lateral column of spinal fibres, is now very probable. These and other results were illustrated by maps and by Aeby's brain phantom, made of colored cork and wire.

DR. A. G. HOEN, then described a simple and inexpensive method of

PHOTOGRAPHING WITH THE MICROSCOPE.

He said that tissues, as ordinarily cut and stained with carmine, are admirably adapted for photography with the low and medium powers. By placing the sensitive plate at a distance of two, three, or four feet from the objective, and using the eye-piece in conjunction with the objective, excellent results are obtained. As a means of recording microscopic observation, nothing is so absolutely true as a good photomicrograph; it is especially suited for perishable preparations, such as scrapings from tumors, etc.

The various manipulations of this process, known as the wet-plate process, were then shown as far as it was possible to do so. The character of the negatives exhibited, as also that of the prints from these, proved conclusively that good work could be done without the use of expensive apparatus. In this case the illumination of the object was effected by an ordinary mirror mounted on a movable pivot and fixed to a window-sill having a southern outlook. The use of the blue glass cell so strenuously insisted on by most authors, was found unnecessary; a ground glass, however, placed on the under side of the aperture in the stage of the microscope was indispensable, both to insure an even illumination and to render the rays of light parallel. The preparation of the plates (collodionizing and sensitizing) is so simple that anyone who has once seen the process could easily follow it. After a proper field has been secured ocularly, the instrument is placed in connection with the camera. The exposure is now made by withdrawing the dark slide from the plateholder, and according to the lenses used a longer or shorter time is given. The development, conducted in the dark-room, is secured by a solution of iron and acetic acid. The process commends itself by its extreme cheapness, $25.00 being sufficient to supply the camera, bath, dishes, etc., with all the necessary chemicals used. Another great advantage which the wet plate possesses over the dry is that a few seconds more or less underexposure does not affect it harmfully, whereas in the dry plate either one way or the other is sure to be ruinous unless in the hands of a very skilful developer.

DR. SAMUEL THEOBALD read a paper on

PREVENTABLE BLINDNESS.

He said that his experience in the treatment of diseases of the eye had led him to the conclusion that in fully fifty per cent. of the cases, blindness ensues from preventable causes. Under these circumstances no apology should be required for introducing this subject. In many instances this is due to the ignorance or criminal carelessness of parents and others; but too frequently the fault lies with the medical attendant, whose superficial knowledge of the diseases of the eye is the cause of the untoward result. *Purulent conjunctivitis of infants* probably causes more blindness than any other eye

disease, but, if judiciously treated from the beginning, it can almost always be brought to a favorable result. He recommended the use of a solution of boracic acid (gr. v–x to aq. destil. ℥j) to be dropped into the eye, and, in severer cases, a saturated solution (gr. xviij to ℥j), or nitrate of silver with the ten grain solution of boracic acid, in the proportion of gr. j–iij to ℥j. Occasionally sulphate of zinc (gr. j to ℥j), or alum (gr. ij–iij to ℥j), may be substituted for the nitrate of silver with advantage, also solution of atropia. If judicious treatment could always be applied to this one disease only, an appreciable diminution in the number of pauper blind would soon be seen.

Scrofulous ophthalmia is another fruitful source of blindness among the children of the poor, but, if properly treated, loss of sight ought never to result. Build up the system with iron and bark, use a collyrium of sulphate of atropia (gr. i–iv to ℥j, according to the severity of symptoms) two or three times daily, and apply a bit of yellow oxide of mercury ointment (gr. j to vaseline ℥j) once a day.

Another very common cause of blindness is iritis, and yet of this affection too the same thing may be said. Too often it is neglected or mistaken for conjunctivitis with an equally unfortunate result. The liberal use of a strong solution of atropia (gr. iv–viij to ℥j) to produce as soon as possible thorough dilatation of the pupil, is the most important indication in iritis, the local abstraction of blood is frequently demanded, and constitutional treatment almost always, as there is usually a history of syphilis or rheumatism. Granular ophthalmia is another disease which destroys ten times as many eyes as it should, and chiefly for want of care in those who could by proper hygienic measures circumscribe its ranges. Sympathetic ophthalmia again annually adds largely to the blind population of our community, because of the willingness of those who have lost the sight of one eye to risk the other rather than submit to having the blind eye removed. Wherever the eye continues irritable, sensitive to the touch, and subject to recurrent attacks of inflammation, it should be removed without delay.

Glaucoma causes many more cases of blindness than it should, because its true nature is so often overlooked. It is of the greatest importance that this disease should be diagnosticated at the earliest possible moment, for in the more acute varieties the delay of a few days in the performance of iridectomy may make the difference between total blindness and complete restoration. Acute glaucoma is most apt to be mistaken for neuralgia of the fifth nerve, and chronic, non-inflammatory glaucoma is not infrequently confounded with simple cataract. Both these errors should be guarded against.

Many eyes are lost annually by those engaged in stone-cutting, etc., by their neglect of the common precaution of procuring a pair of protective spectacles.

Many other ways in which the sight is needlessly lost might be pointed out, but enough has been said to show the great importance, in the first place, that doctors generally should take more pains to familiarize themselves with those diseases of the eye which are liable to destroy the sight; and, secondly, that they should insist more strongly with their patients that it is never safe to look upon any inflammation of the eye as a trivial matter, and to impress upon them that promptness in the employment of remedies is essential, and that frequently blindness is the penalty paid for procrastination.

DR. J. J. CHISOLM read a paper on

REMOVAL OF A PIECE OF IRON FROM THE VITREOUS CHAMBER BY MEANS OF THE MAGNETIC NEEDLE.

After describing the results caused by the presence of foreign metallic bodies in the different parts of the eye, with the means usually employed for their removal, Dr. Chisolm said that whilst the properties of the magnet have been known for so long, it is remarkable that the idea of utilizing them for this purpose is only a very few years old. The first attempt to remove a foreign body from the eye with the magnet was made by Dr. McKeown, of Belfast, in 1874; but his instrument was so crude that his suggestion did not meet with favor. Five years later, Dr. Hirschberg, of Berlin, devised an appropriate magnet, and successfully removed a piece of iron from the interior of the eyeball. The needle was still further improved and perfected by Dr. E. Gruening, of New York, who has succeeded in combining the necessary properties of power and compactness. Dr. Chisolm then described a case in which he had extracted a considerable fragment of iron from the eye of a mechanic with this instrument. The patient whilst chipping off the edge of a boiler plate was violently struck in the right eye by one of the iron chips. On recovering from the first shock, he found that he had lost sight in the injured eye. Dr. Chisolm found the eye presenting the following conditions:

The anterior chamber was full of clotted blood, and only perception of light remained. There was a small wound in the lower part of the cornea. This was the only apparent injury, and the patient was of opinion that as the piece of iron must have been comparatively large it must have only struck the eye without entering it. He felt no special pain in the eye beyond a general stiffness of the lids and fulness of the eyeball. A small wound in the eyebrow was sufficient to explain the stiffness. Dr. Chisolm, however, though seeing no reason to doubt this explanation, probed the wound carefully with the smooth magnetic needle. It had not entered the blood-clot in the anterior chamber one-eighth of an inch before he felt the slight jar caused by some metallic fragment jumping towards it, and on the third attempt he drew out, through the wound, a splinter of iron half an inch long and weighing four grains. Cold-water dressing was applied, and a strong solution of atropia was instilled, and in three days the eye had cleared up and could be freely explored. The pupillary edge of the iris had been cut and the lens transfixed by the piece of iron in its passage, causing a traumatic cataract with largely ruptured capsule and leaving a ragged pupil which, however, had dilated under the atropia. In two weeks the eye gave so little trouble that the patient returned to his employment. Dr. Chisolm then described a somewhat similar case in which, however, the magnetic needle was not introduced till two weeks after the accident, and then detected nothing. Finally it was necessary to remove the eyeball, which was found to be completely disorganized in its interior. Embedded in a blood-clot, hardened by inflammatory exudation, he found a small fragment of iron, which was the cause of the injury. Probably it was too firmly embedded for the magnet to detach it.

FRIDAY, APRIL 25—FOURTH DAY.

DR. ST. GEORGE W. TEACKLE read a paper entitled

RESULTS FROM THE INVESTIGATION AND STUDY OF COWPOX,

in which he arrived at the following conclusions: 1. That cases identically similar to those from which Jenner conceived the grand idea of vaccination as a preventive and ameliorator of smallpox, and from which the first vaccination was performed, are continually occurring, especially during visitations of smallpox. 2. That in looking for a spontaneous case of cowpox independent of all contagion, atmospheric or otherwise, we are looking for something that does not exist, and did not in Edward Jenner's time. 3. That owing to the more convenient and perfect inoculation of the heifer by direct insertion of smallpox virus, a fresh and reliable virus can be obtained whenever smallpox exists.

DR. CONRAD then made some remarks on the

TREATMENT OF THE INSANE WITH SUICIDAL TENDENCIES.

He said that the insane who are inclined to suicide can be treated either by close watching, which is a method involving much expense and trouble, or by the straight-jacket, which is efficacious but very painful. He himself prefers the use of gloves of his own invention, which are far more comfortable. The gloves are stiff, and perforated to prevent sweating. They are joined together at the tip, and attached, but not closely, to the waist. He gave some cases illustrative of the value of these gloves.

DR. TEACKLE considered the gloves a great improvement on the straight-jacket.

DR. TIFFANY asked whether, when a person is bent on suicide, it can be prevented?

DR. CONRAD answered that they can for the time being be prevented, and if they can be prevented for a certain length of time they may outgrow the tendency, as has been the case in several of his patients.

DR. G. H. ROHÉ read a paper on

CERTAIN PRACTICAL POINTS IN THE PATHOLOGY, CLINICAL HISTORY AND TREATMENT OF CANCER.

After alluding to the indefinite manner in which the term *cancer* is too often applied, and to the consequent failures in treatment, he said that although absolute certainty in diagnosis was not to be hoped for, we may unhesitatingly subscribe to the statement of Dr. S. D. Gross that, "Just in proportion as our knowledge of morbid structure is positive, accurate, and comprehensive, will be the probability that we shall become skilled diagnosticians." He said that whilst the most eminent observers still hold contradictory views as to the special tissue to which the origin of cancerous growth is to be referred, it may be considered that the invariable anatomical condition present is *epithelium out of place*. He described the various theories held by Billroth, Rindfleisch, Koster, and others, as to the derivation of these epithelial cells, and said that the doctrine of Waldeyer, that "cancer is always developed from preëxisting epithelial tissue, *i. e.*, from those structures which are built up out of the upper and lower germinal layers of the embryo," seems to have the weight of authority and of clinical evidence in its favor. There is at any rate now no disagreement upon the point that the *one* histological condition is the presence of epithelial cells, confined or infiltrated in a stroma of connective tissue.

Although the ultimate cause of morbid growths seems to lie in an indefinable constitutional predisposition, Dr. Rohé considers that cancer is not either primarily or secondarily a constitutional disease in the sense that syphilis is. Even where the constitutional tendency exists, the local irritation is needed to cause the disease, *e. g.*, cancer caused by irritation of a pipe, in chimney sweeps by the irritation of the scrotum with soot, etc.

He called attention to the fact that morbid growths of an epithelial nature, but ordinarily innocent, may become malignant, such as warts, keratoses, papillomata, etc. Of this, he gave some instances which had come under his own observation. Some facts in the pathology of cancer shed light upon its clinical history, and may be considered with profit. *Pain* is a symptom popularly believed to be a constant accompaniment of cancer. So it generally is; but Dr. Rohé had met with at least four instances in which it was absent. He gave the particulars of one of these cases, in which the patient, a lady seventy-four years of age, complained of no pain, but died, nine months after he first saw her, of exhaustion, consequent on the drain on the system of a very extensive cancerous growth. Simple ulcers often cause far more pain than cancer; hence, pain cannot be relied on as a diagnostic symptom. *The induration of the morbid growth, or of the resulting ulcer*, when taken alone, is no more a characteristic symptom of cancer than that just mentioned. In cases of suspected cancer *induration of neighboring lymphatic glands* is one of the first points to be looked to for confirmatory evidence; but it should always be borne in mind that glandular enlargement is not synonymous with glandular *infiltration*. Dr. Rohé spoke of the fact that the malignancy of cancer is largely due to its tendency to produce similar growths in other parts of the body — secondary deposits, metastasis, or general infection, so called. He then described the various ways in which this takes place. As to the curative measures to be adopted, he said that in rare instances the cancerous ulcer does spontaneously cicatrize. There is really no such thing as the *cancer cachexia*, the cachexia which follows cancer being simply the result of the general breaking down of the system. He strongly recommended early operative measures, for, although there is apt to be a recurrence, the relief to the patient, the prolongation of life, and the possibility of a cure, afford amply sufficient reasons for an operation. He recommended the administration of arsenic, pushed to the limit of physiological tolerance, as very useful in modifying the tendency to epithelial degeneration.

DR. J. N. MACKENZIE described

TWO CASES OF REFLEX COUGH DUE TO NASAL POLYPI.

In both cases a dry, hacking cough had been present for years, and the patients suffered besides from obstruction of the nostrils, attacks of coryza, loss of appetite, etc., leading them to apprehend disease of the lungs. On examination, nasal polypi were discovered and removed, with the result in both cases of complete and speedy relief from the cough and other symptoms. Dr. Mackenzie said that the dependence of asthmatic attacks upon the presence of polypi in the nasal chambers is

sufficiently common, but the important *rôle* of the latter in the production of cough, has been apparently overlooked. He said that, so far as his experience went, cough is only present when the growths spring from, or in some way or other are brought in contact with, a portion of the erectile area, and generally its posterior portion. When the polypus is in such a position that it does not come in contact with this sensitive surface, no cough is produced. Dr. Mackenzie does not consider that the polypus is in itself provocative of cough or asthma, but only provokes it by irritation.

Dr. L. McLane Tiffany read a paper on

THE RESULT OF OPERATIVE MEASURES FOR RECTAL CANCER, WITH REPORT OF CASES.

He said that in operations undertaken for the relief or cure of malignant disease of the lower bowel, the result is considered good if prolongation of life with relief from pain is obtained. The experience of any one man in such cases can be but limited; it is only by uniting the experience of many that we can hope to discover the rules to guide the surgeon. He had already published the accounts of five operations which he had performed for cancer of the lower bowel, in different journals, and as at the time of publication the ultimate result was known only in one case, he would now proceed to report it as regarded the four others. In three cases the colon was opened in the left loin to avert impending death from obstruction; once the colon was opened in the same situation for the relief of pain without complete obstruction, and once the lower rectum, with anus, was excised for epithelioma. In two of the cases, in which left lumbar colotomy was performed, the patients lived respectively fifteen and seventeen months after the operation. In both cases the relief from pain was entire, and in both death was caused by asthenia. In the third case death was from pelvic cellulitis, after abortion, about three months after the operation. The patient had already missed two menstrual periods before the operation, but there was complete obstruction of the bowel, calling imperatively for interference. The presence of the fœtus in nowise complicated the colotomy, and but for the rapid increase of the cancer the child might have been carried to term. In the last case, in which the lower rectum, with anus, was excised, there had been no return of the disease twenty-one months after the operation. The rectum seemed to be in all respects healthy, and there was no incontinence of feces.

Dr. Charles G. Hill read a paper entitled

THE COMMON SASSAFRAS—A POTENT DRUG AND A DANGEROUS NARCOTIC.

He said that, whilst sassafras has ceased to be considered officinal by the profession, it is still largely used as a domestic and patent medicine. His attention had been called to its powerful narcotic properties by the case of a boy who, after taking two "large swallows" from a bottle of the oil of sassafras, shortly became very stiff, and fell on the floor almost unconscious. He was recovered from this condition by the administration of a violent emetic and by copious draughts of warm water. Wishing to investigate the subject further, Dr. Hill undertook a course of experiments with this drug on mice, cats, and dogs, which he described, with results which convinced him that, instead of being an innocent and useless drug, the common sassafras possesses properties of the most potent character as a narcotic, a germicide, and an antiferment, and, if properly understood, may prove a valuable addition to our therapeutics, but if ignorantly and carelessly used may become dangerous and even fatal to human life.

Dr. Eugene F. Cordell reported a case of

CONGENITAL ABSENCE OF ONE OF THE VALVES AT THE MITRAL ORIFICE.

The case was of especial interest, not only from the rarity of the affection—all the other valves being perfect—but also from the fact that he had diagnosticated the mitral insufficiency before the child was born from the peculiarity of the sounds heard when auscultating the fœtal heart. The child died soon after birth, and the parents gave their consent to an autopsy. The heart was shown to the members of the Faculty after the reading of the paper. After looking over a large amount of literature bearing on the subject, he had not been able to meet with a similar case.

A joint paper by W. H. Howell, Fellow of the Johns Hopkins University, and Dr. F. Donaldson, Jr., was then read, on

THE MAXIMUM VOLUME OF BLOOD SENT OUT BY THE LEFT VENTRICLE IN A SINGLE BEAT, AND THE INFLUENCE OF VARIATIONS IN VENOUS PRESSURE, ARTERIAL PRESSURE, AND PULSE-BEAT UPON THE WORK DONE BY THE HEART.

It was observed that the methods hitherto used in estimating the quantity of blood pumped out from the left ventricle at each systole have been so indirect that little reliance can be placed upon them. The results obtained by Volkmann, Vierordt, and Fick were adverted to. They varied considerably. Dr. Donaldson and Mr. Howell, in their experiments upon this important and interesting point, made use of a dog's heart, completely isolated from all other organs of the body by Prof. Martin's method. By this method the quantity of blood ejected from the left ventricle at each systole under varying conditions of venous pressure, arterial pressure, and pulse-rate can be determined directly by catching the blood as it is pumped out from the tube connected with the aorta of the dog.

The main results of these experiments were as follows: The ratio of the maximum weight of blood pumped out from the left ventricle at each systole to the body-weight at the normal pulse-rate (120 per minute) of the dog is about $\frac{1}{70}$th, or .0014. Probably this represents very nearly the average quantity pumped out at each systole in the living dog. The precise calculations, value of the venous pressure, etc., employed in these experiments were given in support of this conclusion, and it was added that since there is so much difference in the pulse-rate between the dog and man, no inference can be made with certainty from the results obtained with the dog to the case of man.

Variations in arterial pressure have practically no direct effect whatever on the quantity of blood sent out from the left ventricle at each systole. Variations of from 58 to 147 millimetres were tried, and the amount of blood remained maximal throughout, the heart, of course, working more or less in direct proportion to the

arterial pressure against which it worked within the limits named. The venous pressure on the right side was gradually increased from 10 centimetres to 60 or 70 centimetres, and the outflow from the aorta measured for each venous pressure used. It was found that the outflow from the left ventricle, and, consequently, the work done by it, increases with the venous pressure—but not proportionally—up to the point of maximum work.

The most direct factor influencing the quantity of blood sent out from the ventricle is the intraventricular pressure, by which it is distended during diastole. During life, this pressure must be mainly owing to the action of the auricles, since the pressure in the great vein emptying into the auricles never rises to any important, positive value.

The rate of beat of the heart was varied in these experiments from 228 to 77 beats in a minute, and back again to 140 in a minute, and so on. The results were that the total outflow and the total work done during any given period of time decreases with a diminished pulse-rate, and increases with an increased pulse-rate.

DR. MICHAEL gave notice that he would move an

AMENDMENT TO THE CONSTITUTION,

to change the words "any gentleman" to "any person" in the clause relating to the admission of members.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—T. S. Latimer, M.D.

Vice-Presidents.—Drs. John R. Quinan and I. E. Atkinson.

Secretary.—Dr. G. Lane Taneyhill.

Assistant Secretary.—Dr. Robert T. Wilson.

Corresponding Secretary.—Dr. T. Barton Brune.

Reporting Secretary.—Dr. Richard Henry Thomas.

Treasurer.—Dr. W. F. A. Kemp.

Executive Committee.—Drs. P. C. Williams, Thomas F. Murdoch, L. McLane Tiffany, John S. Lynch.

After a vote of thanks to the Trustees of the Johns Hopkins University for the use of Hopkins Hall, the Faculty adjourned *sine die*.

THE AMERICAN SURGICAL ASSOCIATION.

Fifth Annual Meeting held at Washington, April 30, May 1, 2, and 3, 1884.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, APRIL 30TH—FIRST DAY.

THE meeting was called to order in the Hall of the National Museum Building by the PRESIDENT, DR. E. M. MOORE. The Secretary, Dr. J. R. Weist, read the minutes of the last meeting, which were adopted as read.

THE PRESIDENT, E. M. MOORE, M.D., of Rochester, N. Y., then delivered the *President's Address*, choosing for his subject,

EARLY AND LATE OPERATIONS.

After a few remarks in recognition of the distinction conferred upon him in his election to the office of President of the Association, and in commendation of the noble work done in the organization and support of the Association by his predecessor in the office, attention was called to the unmistakable need of a society of this kind. Herodotus tells us that the early Egyptians recognized the necessity of dividing the profession into those treating the internal diseases and those treating the external—the therapeutic and the mechanical; the peripharmicon and the periorganon. The peripharmicon has been lost, until recently the mummy of a distinguished physician has been found, wrapped in a papyrus, which gives us at least a portion of the therapeutic methods of the Egyptians fifteen hundred years before Hippocrates. Unfortunately, he said, the subject-matter is not surgical, and we have but to hope that the periorganon may yet be unrolled from the remnant of one of our own special craft. It is to be regretted that the religion of this writer forbade his publishing his name. Although Hippocrates was thus, in all probability, only a teacher of what had gone before, we must still revere his name, both because of the excellence which he must have attained and the common sense which pervades all his works.

The speaker then referred to the manner in which surgery is altered by its surroundings. It has always flourished when the mind was liberated from unnatural restraint. It is the marvellous combination of the practical surgeon and the philosopher that marks the broad, rounded character of greatness. How little of wide, popular recognition one of our profession enjoys, he said, is peculiarly illustrated in the appreciation of the great contemporaries—Pericles, Socrates, and Hippocrates, the metaphysicians and the physician. While most of the methods employed by Hippocrates have been replaced and surpassed, there can be no doubt of their successful application in his time. Another striking point in ancient surgery is the importance of operations now little thought of; and in many of our modern methods we recognize merely another form of those used by the ancients.

From this early time, the speaker passed directly to the time of the renaissance, an epoch which he said had been one of the most fruitful in all literature, the intervening time being productive of naught. The school of Salernum, he said, assisted in nothing but the retention, in a limited way, of the ideas of the past. At the time of the renaissance we meet Vesalius, a son and a grandson of physicians. Notwithstanding the great intellect of the man, however, had not the grand current of cultivation been in full flow, we should not have had a Vesalius. But if Vesalius had not lived, Eustachius, born six years after, would have taken his place. His aim was broader than that of Vesalius, and he laid the foundation of comparative anatomy.

From this wonderful time the great movement of medicine has gone on with an ever-widening stream. Next came Fallopius, then Fabricius and Harvey, and now vivisection is added to the means of investigation. The days of Perkins's tractors, Hahnemannism, eclecticism, etc., are reserved for a later date. The literary exaltation soon ran into absurdities. At the present day we are almost dazed with print, and hence there are attempts to codify knowledge; hence the retrospects, manuals, and year-books, to compress for our understanding the fertility of invention.

Reference was then made to the advance in the more important and recent operations—ovariotomy, nerve-

stretching, gastrotomy, etc. This is the golden age of inquiry. The particular movement of the day is toward specialties. The large *clientèle* of a well-known specialist is the assurance of wealth. That excellence follows large experience in narrow lines is obvious, but is there not reason to fear, the speaker asked, that a specialist who is not well informed, both by learning and practice, is apt to blunder? This is the great danger of the day. An Association such as this is the need of the present; one that represents the broad and not the narrow lines of surgery. The future to America is big with promise. The institutions which have fostered medical learning are worthy of all praise. The fabulous accumulation of wealth during the last twenty-five years occasionally induces its possessor to honor himself by the patronage of learning. We have a Johns Hopkins University, and we believe others will follow. The future worker in medicine will always reach closer and closer to the law of disease, and perhaps the exact statement which the chemist can make in definite proportions may at length crown the labors of the therapeutist: "All things are divine, but also scientifically determinable."

DR. BASIL NORRIS, Chairman of the Committee of Arrangements, made a brief report, showing that the necessary arrangements had been made, and welcomed the Association to Washington.

THE REPORT OF THE SECRETARY

showed that there are ninety-three Fellows in the Association, and three honorary members. Since the last meeting, Honorary Fellow Dr. A. C. Post and Fellow Dr. George A. Peters, both of New York, have resigned, their action being necessitated by the communication addressed to them by order of the Association, asking all members who opposed the National Code of the American Medical Association to withdraw. Dr. Markoe, who was elected a Fellow at the last meeting, declined the membership. Honorary Fellows Dr. J. Marion Sims and Dr. Willard Parker have been removed by death. The report further stated that a number of members have not yet replied to the communication addressed to them in regard to their allegiance to the Code of Ethics.

DR. J. EWING MEARS then read the report of the

COMMITTEE ON PUBLICATION.

He stated that the volume of *Transactions* had been printed as directed, and disposed of as ordered. Communications were also read from the Royal Medical and Chirurgical Society, London, King's College, London, The Royal College of Surgeons, of England, John Eric Erichsen, London, Bobb's Library, Indianapolis, The College of Physicians of Philadelphia, and the New York Academy of Medicine, acknowledging the receipt of copies of the *Transactions*.

DR. B. A. WATSON, of Jersey City, then read a paper on

AN EXPERIMENTAL STUDY OF ANÆSTHETICS.

The author introduced his subject by stating that it was the aim of his paper to show, by experiments on rabbits and dogs, the physiological action and relative safety of those anæsthetics which are most frequently used by surgeons. The anæsthetics employed were chloroform, sulphuric ether, bromide of ethyl, and various mixtures of these drugs.

The observations in these experiments were chiefly limited to the temperature, pulsations, respirations, mortality, and *post-mortem* appearances; but the conclusions reached through the experimental investigations made by Dr. H. C. Wood, of Philadelphia, for the purpose of determining the physiological action of chloroform, sulphuric ether, and bromide of ethyl on the heart are likewise mentioned.

The introduction to this article was followed by a brief explanation of these experiments, which was intended to prepare the reader for a full comprehension of the work performed, and which was connected with the anæsthetizing of eighty-two rabbits and twenty-five dogs. Following these explanatory notes, there were presented in a tabulated form the general results, which are contained in ten tables, six of which relate to the experiments performed on rabbits, and four to those on dogs.

The tables are followed by a comprehensive *résumé* of the results, and the author remarks that their most casual inspection cannot fail to impress the observer with the relatively small mortality produced by the sulphuric ether, when it is compared with that which followed the use of the bromide of ethyl, chloroform, or the mixtures which were employed.

The percentage of the mortality produced by the different anæsthetics employed in the experiments on rabbits was as follows:

Sulphuric ether, ...	16⅔
Chloroform, ...	62½
Bromide of ethyl, ...	50
Alcohol, chloroform, and ether mixture,	75
Alcohol, chloroform, and ethyl mixture,	66⅔

Attention is called to the fact that owing to the evanescent character of the bromide of ethyl, it was found impracticable to keep the rabbits constantly under the influence of this drug or its mixtures; and consequently the figures given in the above do not accurately represent the mortality which may justly be anticipated when these animals are kept under its full influence for two hours—the period during which full anæsthesia was intended to be continued in all of the experiments. The above comments are entirely limited to the administration of the bromide of ethyl and its mixtures to the rabbits, the same not applying in any degree to the dogs, or to any other anæsthetic. The whole number of dogs experimented on was twenty-five, and among these, twelve deaths occurred, in which the percentage of mortality chargeable to the different anæsthetics was as follows:

Sulphuric ether, ...	.00
Chloroform, ...	.00
Alcohol, chloroform, and ether mixture,	.80
Alcohol, chloroform, and ethyl mixture,	.80
Bromide of ethyl, ...	100.00

It is shown by the above comments, and others which follow in the author's detailed statements, that the danger arising from the use of the bromide of ethyl and its mixture is more accurately portrayed in the experiments on dogs than in those on rabbits. The author finally reaches the conclusion that the *primary effect of the bromide of ethyl resembles that of chloroform*, and not that of ether; but it is certainly much more dangerous than the former agent, especially when full anæsthesia is continued with it for a period of two hours. The

deaths which occurred in the experiments, during the administration of the ethyl, are believed to have been caused by its paralyzing action on the heart, while those occurring at a later period were probably more or less dependent on the same; but in these cases the *post-mortem* appearances reveal extreme congestion of the principal visceral organs, with other indications of inflammation in all cases in which death was sufficiently delayed.

We have now reached a point in our study of the various anæsthetics where we believe we are justified in *firmly asserting*, in the light of the theoretical and practical knowledge which we now possess of the action of the bromide of ethyl, that neither this drug nor its mixture should ever be employed for the production of anæsthesia, especially where it is necessary to prolong this state. It has long since been sufficiently shown that sulphuric ether is decidedly the safest anæsthetic which has yet been employed in general surgical practice; and our experiments are merely confirmatory of the correctness of this decision. The use of a mixture of alcohol, chloroform, and ether, for the purpose of producing anæsthesia, is theoretically wrong and practically bad, since it is unquestionably much more dangerous than sulphuric ether.

DR. W. W. DAWSON, of Cincinnati, in opening the discussion, said that he believed the sentiment of Dr. Watson's paper was correct. He had had a rather painful experience with chloroform, and narrated two cases which had terminated fatally. The first was in 1868, before the agent was considered dangerous. He was amputating a foot. The field of operation became bloodless; artificial respiration was practised without success. At that time, he said, we were unwilling to admit that chloroform could kill, it was so prompt in its action. The second case lost was that of a little boy. In that case, also, the first symptom was the cessation of hemorrhage from the field of operation. The anæsthetic was for a moment withdrawn. The patient revived, and the operation was proceeded with. Soon the operation again became bloodless, and the same occurred a third time. This time it was permanent. The heart had ceased to beat, and failed to start even after the most energetic artificial respiration.

The speaker further stated that since this experience he was very cautious in the use of the alcohol, chloroform, and ether mixture, and preferred ether alone. He further reported the case of a woman who, although she had several times taken chloroform during parturition, and at one time had remained under its influence for an hour, died after a few inhalations in a dentist's chair.

PRESIDENT MOORE called attention to the fact that the woman just spoken of was in all probability in an erect posture when inhaling the ether, a position which renders the danger much greater.

DR. DONALD MACLEAN, of Detroit, spoke strongly in favor of chloroform. He did not believe the dangers from its use much, if any, greater than those from ether. He has used it almost exclusively in his practice. A great deal of the danger, he believed, is in the mental impression made by using the anæsthetic. Other cases, too, die from other causes than the action of the anæsthetic. In this connection he reported the case of a woman whom he saw a week ago. She was a robust woman, apparently in perfect health, except a slight asthmatic dyspnœa, a common affection in Michigan. He decided to operate in a few days for an ovarian tumor. He had been away only an hour when she died. Had the operation been in progress, or had the patient taken a breath or two of chloroform, her death would have been attributed to it. He had never seen death from an anæsthetic, and had had trouble in only very few. The last case in which there was any cause for alarm was that of a man from whom he had just removed the entire tongue. The instrument not working perfectly, there was some hemorrhage. Blood was drawn into the larynx, but after removing the blood, and practising a little artificial respiration, all came right. In conclusion, he stated that while he believed in the use of chloroform, he believed it equally important that the agent be administered by a competent person, able to recognize and handle any complications that may arise.

DR. WILLIAM A. BYRD, of Quincy, Ill., took his stand with those who opposed the use of chloroform. He had lost but one case, and that a woman who had been operated upon several times before coming under his care, for a vesico-vaginal fistula; being once nine hours anæsthetized. He had also kept her under chloroform for an hour without any symptoms of danger, and the fistula was closed. When, however, he went to remove the stitches, the patient demanded an anæsthetic. She took only a few inhalations, when she suddenly died. He further spoke extensively of the action of the bromide of ethyl. He had at first used it with the fullest confidence, but had abandoned its use later, on account of its action being so profound and causing such marked suffusion of the face. He now uses a mixture containing one ounce of ethyl bromide, three ounces of ether, and two ounces of alcohol. The action of this, he said, is prompt, efficient, and, as far as his experience goes, safe.

DR. L. MCLANE TIFFANY, of Baltimore, said that he must negative absolutely the statement of the essayist in regard to the similarity of action between the bromide of ethyl and chloroform. Clinically, the action is different. He had never had a fatal case due to chloroform, although he had seen patients in great danger. No one, he believed, could use it with perfect confidence; and he referred to the experience of the late Dr. Sims, who after having most excellent results from its use, lost a case shortly before his death. He referred to the practice of Dr. Chisolm, of Baltimore, who uses the ethyl bromide in ophthalmic operations, with no inconvenience.

DR. P. S. CONNER, of Cincinnati, stated that he had used the bromide of ethyl pretty extensively in the Cincinnati Hospital. He had been both surprised and astonished at its action on the heart. He had seen the pulse run up from 100 to 120 during its administration. He had never seen an agent so mild and efficient in its action, and yet so profound, and apparently not dangerous. He did not believe that any anæsthetic agent can be called safe. It is impossible, he said, to carry patients to the border-line of life, without now and then some one slipping beyond that line. Such being the case, he believed it the duty of the surgeon to employ the agent of least danger.

At the suggestion of the President, the discussion was

suspended for the reading of the paper of DR. DAVID W. CHEEVER, of Boston, on

SOME OF THE DANGERS AND DISADVANTAGES OF ANÆSTHESIA.

The essayist stated, in the beginning of his paper, that the form of anæsthesia to be considered was that produced by sulphuric ether. Deaths from ether are rare; the speaker had not seen one in an experience of twenty-six years. The largest statistics give one death in 23,204 cases. The vast array of advantages connected with the anæsthetic state, coupled with the comparative freedom from danger, have masked dangers which may arise. Ether can kill, and there are operations that can better be done without it. The speaker then passed to the consideration of the dangers themselves. The danger in breathing ether, he said, is chiefly from impeded or failing respiration.

The first cause of danger to the respiration is the production of stertor and the falling back of the tongue.

Second, in some persons, and we cannot foresee in whom, the mucous membrane of the throat and air-passages is very sensitive to the fumes of ether, a difficulty first shown in croupy respiration, and soon followed by the flow of a frothy mucus.

Third, a most dangerous complication is tetanic setting of the inspiratory muscles of the chest. No air enters; respiration with the diaphragm fails to fill the lungs, and the patient dies as in true tetanus.

Fourth, simple exhaustion is another source of danger. Death may occur from slowly failing respiration, so gradual as not to attract attention.

Fifth, disease of the heart may cause death during the inhalation of ether. Well-marked valvular disease, pericarditis, and effusion, or a fatty or feeble heart, may contribute to a fatal result, and yet persons with valvular disease have frequently been anæsthetized in safety, by using caution and taking plenty of time.

Sixth, apoplexy, sanguineous or serous, may follow the coma of etherization in the old or in drunkards. Atheromatous vessels may give way under the great congestion produced, and the "wet brain" of alcoholism may succeed the stupor of ether.

The author now passed to the consideration of the disadvantages of anæsthesia. Etherization, in his opinion, does diminish primary shock; it removes apprehension and annuls pain, but it does not remove the secondary shock which follows an operation. While the primary effect of ether is stimulating, the secondary is exhausting. Another marked disadvantage of anæsthesia is that it decoys the operator into delay and slowness. Drunkards and steady drinkers succumb slowly to the anæsthesia of ether; they pass through a long period of excitement and delirium, and they are subject to persistent and recurrent tremor, which delays an operation, or jeopardizes its safe execution. Vomiting and lasting nausea are also among the disadvantages. This is especially disastrous in abdominal sections, in operations for hernia, and in sections of the cornea and iris. Lastly, intoxication and delirium, on coming out of anæsthesia, are especially injurious after a simple or, worse still, after a compound fracture has been set.

The following operations, Dr. Cheever believed, may be better done without anæsthesia: extraction of cataract, tracheotomy for disease, and paracentesis thoracis. He stated further that there is no doubt that complete anæsthesia during parturition leads to tardy contraction of the uterus after labor. It is a noteworthy fact that most deaths from ether occur during operations on the rectum, perineum, or vagina, the reason being that the surgeon, from his position, cannot well watch the condition of his patient. The essentials for giving ether are, an empty stomach, a loose neck, a free abdomen, an easy, semi-recumbent position, a sponge wrapped in towels for the ether, and a gag and forceps for the tongue. The paper closed with a few directions in regard to the treatment of some of the more common dangerous symptoms, and with the advice that in order to avoid asphyxia, nausea, headaches, and be *safe*, only the purest anhydrous sulphuric ether should be used.

DR. T. F. PREWITT, of St. Louis, spoke of the importance of the question under consideration. He agreed fully with Dr. Watson that ether is the safest anæsthetic agent. He never had a fatal case, but had had cases in which difficulty was experienced in reviving the patient. He congratulated Dr. Maclean on his satisfactory experience, but feared that he would yet have a reverse. He had been in the habit of using chloroform in operations upon children, and believed that it was safe, but he thought the case reported by Dr. Dawson an important one in this regard. In regard to the method of administration, he preferred the simple cone made with a towel, covered with paper, and containing a sponge. He said, however, that he had frequently seen half an hour consumed in producing anæsthesia.

DR. BONTECOU stated that he had seen probably a thousand individuals anæsthetized with chloroform before ether came so universally into use, but that he had never seen a fatal case. He however reported the case of a man who died on the table after being anæsthetized with ether, but could not state whether the death was from shock or from the operation. Since 1865 or 1866, the speaker had always used ether, not so much from preference as in deference to the sentiment of the profession in regard to the dangers of chloroform.

DR. NANCREDE referred to a method of drawing the jaw forward, as well as opening the mouth, in order to relieve asphyxia.

DR. PARKS referred to the danger of introducing blood into divided veins by performing artificial respiration, especially in operations about the neck.

DR. GEORGE W. GAY reported that he had been for twenty years connected with a large hospital in Boston, where the use of ether was a daily occurrence, but they were afraid to use chloroform on account of prejudice. The rule there is to give ether slowly. The speaker described the inhaler used. There is another method, he remarked, which had just been tried at the city hospital. It is the administration of ether by the rectum. The evaporation of the fluid from a bottle being hastened by warm water, and the vapor conducted into the rectum by means of a rubber tube. In three cases in which it was tried it acted satisfactorily.

DR. DAWSON reported two cases; one in which, in order to produce sufficient anæsthesia to perform a perineorrhaphy, he was compelled to give chloroform in addition to ether; and another in which, even with chloroform, he was unable to get the patient quiet, but had literally to cut for stone "on the wing," as he expressed it.

DR. CAMPBELL, of Augusta, had also experienced a similar difficulty in operations upon the perineum.

DR. BASIL NORRIS, U. S. A., wished to emphasize the importance of administering chloroform only with the patient in the recumbent posture. He also reported a case in which he had seen a distinguished French surgeon almost lose a patient, but by the vigorous slapping of the face and chest by an assistant, vitality was restored.

DR. WATSON said that in his statement that the action of the ethyl bromide resembled that of chloroform, he referred only to its action on the heart.

DR. CHEEVER closed the discussion with the statement that, with the jaws apart and the tongue well carried forward, it is only necessary to depress the jaw.

On account of the illness of Dr. S. D. Gross, his paper, on

WOUNDS OF THE INTESTINES

(see page 495), was read by Dr. Richardson.

DR. MACLEAN, in referring to what was said in the paper on the liability to the development of tympanites, said that he believed it, to a great extent, due in many cases to the cathartic medicines employed in connection with the cases. He stated, further, that he did not believe the author of the paper could express a preference for silk suture if he had tried the silkworm gut-suture or horse-hair. Either of these, he said, is less irritating, and has no absorbtive powers.

DR. PARKS expressed preference for the catgut suture in intestinal wounds, because, in his experience, both horse-hair and the silkworm gut are too brittle.

DR. BYRD reported several cases in which he had repaired injured intestines, using in most cases the ordinary silk suture, with good results.

DR. RICHARDSON closed the discussion by calling attention to the fact that Prof. Gross, in his paper, advocated freely opening the abdomen in cases in which injury to the intestine is suspected. He believed, for his own part, that, with our present knowledge of the impunity with which the peritoneal cavity can be handled, the advice of the distinguished author was correct, and he heartily endorsed it.

THE PRESIDENT then read a resolution, to be sent by telegraph to Dr. Gross, expressing regret at his absence, sympathy in his illness, and a hope for his speedy recovery.

DR. L. MCLANE TIFFANY, of Baltimore, next read a paper entitled

A CONTRIBUTION TO THE HISTORY OF LIGATION OF THE COMMON FEMORAL ARTERY.

After referring to the varied advice given by different authors relative to the ligation of the common femoral artery, and the fact that while some express little choice, others prefer the ligation of the external iliac, the essayist reported several cases, with the cause for the operation, its method, and results.

The following conclusions were arrived at:

1. Ligation of the common femoral artery in continuity for distal wound is attended with great mortality.

2. Ligation for elephantiasis and aneurism is proper.

3. The crural sheath should be freely opened, and the vessel carefully examined for the branches of the profunda and epigastric; ligation not to be made within a half or three-fourths of an inch of either.

4. A half or three-quarters of an inch below Poupart's ligament is the best locality for the ligature.

5. The presence of a small branch near the seat of ligature does not contraindicate the operation; such branch should be also tied.

DR. CAMPBELL reported three cases in which he had ligated the common femoral for injury, with a fatal result in each case. He said that almost immediately after the operation the limb became cold, and then shock ensued, the patient dying even before a line of demarcation had time to form. He had had gangrene result, from a ligation of the superficial femoral, below the knee, but the process was quite different from what occurred in these cases; there the necrosis occurred slowly; here, the action was rapid, and death resulted from some impression made on the general system. In cases of aneurism, in which a good collateral circulation has been formed, the result is, necessarily, more favorable.

DR. BASIL NORRIS reported a case which occurred to him and his associates in early army duty, in which they ligated the common femoral for aneurism, the wound healing promptly, and perfect recovery ensuing.

DR. TIFFANY concluded the discussion by thanking Dr. Campbell for so heartily endorsing his conclusions.

DR. P. S. CONNER, of Cincinnati, then read a paper on

TRAUMATIC CEPHALHYDROCELE, WITH A REPORT OF TWO CASES.

The first case was that of a boy, twelve and a half years old, who, as the result of a fall from a wagon, sustained a depressed fracture of the occipital bone, with the formation of a cyst containing a pale, serous fluid, believed to be of cerebro-spinal origin. The case was treated by occasional removal of a part of the fluid and compression. A good recovery was made.

The second case was produced in a different manner, but resulted in a tumor with much the same features.

Reference was also made to twelve other reported cases, and deductions drawn from them relative to the cause, treatment, and prognosis of the injury.

There being no discussion of this paper, DR. CHARLES B. NANCREDE, of Philadelphia, read his paper on

SURGICAL INTERFERENCE IN CEREBRAL ABSCESS.

After referring to the many cases in which death occurs from cerebral abscess without any procedure having been instituted, he reported quite an array of cases in which the trephine had been applied and pus evacuated, either immediately or after puncture of the membranes. One very interesting case was that in which after trephining through the skull unmistakable evidences of the presence of pus were present, but several punctures of an aspirator needle failed to discover its exact location. When a large abscess was opened by the knife and a half ounce of pus allowed to flow, the patient, apparently dead at the time of the incision, revived.

DR. RICHARDSON reported a case in which no evidence of fracture of the skull could be detected during life, but in which the autopsy revealed a very minute fissure, with an abscess in the brain substance.

DR. CAMPBELL narrated the case of a soldier who was struck by the falling débris of a house during a

battle. His skull was fractured. Unmistakable symptoms of abscess followed. The skull was trephined, three or four ounces of pus were evacuated from a large cavity, but respiration immediately ceased, apparently as a result of the removal of the pressure from the brain.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, April 22, 1884.

THE VICE-PRESIDENT, CHARLES MCBURNEY, M.D., IN THE CHAIR.

ELEPHANTIASIS; LIGATION OF THE FEMORAL ARTERY.

DR. L. A. STIMSON presented a woman whose femoral artery he tied four weeks ago for elephantiasis of the leg.

She is fifty years old, and has always been healthy. Twelve years ago she had an attack of erysipelas in the foot, which soon got entirely well, but was followed after a month by another in the right leg which left the limb somewhat swollen; other attacks followed at intervals of two and three months for several years, leaving the limb larger, after each attack, than it was before. She was admitted to Bellevue Hospital, March 4, 1884, with well-marked elephantiasis of the entire right leg from the knee to the ankle, both the foot and thigh being very œdematous and the skin normal. She was kept in bed, firm pressure made on the leg by a roller bandage over a layer of cotton, and an elastic bandage kept upon the thigh. After about three weeks of this treatment the œdema had left the thigh, but the leg was unchanged, and still measured twenty-three and a half inches in circumference. The other leg measured eight and a half inches at the calf. March 24, the femoral artery was tied at the apex of Scarpa's space with catgut, and the limb wrapped in a thick layer of cotton. April 2, the dressing was changed, and the wound found healed; the leg measured twenty-one inches and the foot was much less œdematous. The rubber bandage was then applied snugly to the leg over a layer of cotton, and has been used constantly to the present time, and the patient kept in bed. April 4, the leg measured seventeen inches; April 8, fourteen and three-fourths inches; April 12, twelve and three-fourths inches; and that is its present size.

Dr. Stimson had refrained from using elastic pressure before the operation because the books speak so discouragingly of its efficiency, and he regretted now that he had not used it, even if only to prove such inefficiency, and in a similar case he would give it a thorough trial before resorting to operation. At the same time he felt obliged to call attention to the rapid decrease of the œdema during the first week under the influence of the operation alone, and he thought it quite probable that the ligature and the bandage employed in concert had done much more than either would have done alone.

DR. POST had a case, several years ago, of commencing elephantiasis, occurring in a person who came from the West Indies, and in which great benefit followed continued pressure from the bandage. The disease was in its early stage. When the patient left, there was an approximation to an apparent cure.

DR. BRIDDON saw a case, in the New York Dispensary, several years ago, in which there was considerable doubt as to whether it was a case of obstruction of the lymphatics only, or one of true elephantiasis; but, at all events, marked benefit was afforded by the application of bandages wet with soda water. The condition, however, returned in a measure, due to discontinuance of the treatment, and the return of the patient to his bad habits. Dr. Briddon remarked that, if his memory served him correctly, Dr. Carnochan was the first who treated cases of this kind by ligation of the femoral artery.

DR. LITTLE said that Dr. Carnochan's case was the first treated in this way; only temporary relief was afforded.

DR. E. L. KEYES said that the opinion of dermatologists was against ligation of the femoral artery in the treatment of elephantiasis. The twelfth case operated upon was reported by Dr. Buchanan in the *British Medical Journal*, 1867, p. 465, who reported that nine had been cured; in two improvement occurred, and a third patient died of pyæmia from the operation.

In the *Deutsche Zeitschrift f. Chirurgie*, 1876, thirty-two cases were reported. Of these, there were twenty-three in which ligation of the femoral artery was performed, and of the twenty-three cases there were relapses in all except three. The consequence is that the operation is looked upon as one which may afford rapid amelioration in all cases, perhaps, but it does not give a permanently favorable result. Dr. Carnochan's case (AMERICAN JOURNAL OF THE MEDICAL SCIENCES, July, 1867, p. 109) was one of elephantiasis græcorum, which differed materially from elephantiasis arabum, the malady treated in Dr. Stimson's case, and in most other cases of ligation.

Another case had been reported by Dr. Van Zetti (*Gaz. des Hôp.*, No. 144, 1876, p. 572), in which the femoral artery was tied. A starch bandage was applied, and the patient was directed to go home, and to keep up the pressure by means of such a bandage for some time. At the end of three years the patient returned, having kept up pressure by means of the starch bandage continuously for the entire time, and the result was that the disease had become permanently cured, and the limb was somewhat smaller than its fellow. Dr. Keyes thought that it would be proper to apply pressure, not only to reduce the œdema, but for the purpose of maintaining continued pressure to prevent the disease from starting afresh. So far, then, as the present evidence stands, it is to the effect that the operation always gives benefit, but, generally, it is temporary.

URETHRAL CALCULUS.

DR. JAMES L. LITTLE presented a specimen accompanied by the following history: On October 26, 1883, I was called to see a boy about twelve years of age, who gave the following history: The night before, while playing marbles in a stable, he received a severe contusion of the perineum, by suddenly squatting down and coming in contact with the blunt end of an iron hook. This gave rise to considerable pain and straining without enabling him to void his urine. In the morning, about nine o'clock, his straining efforts were followed by blood and bloody urine. Dr. Gibney was called to see him in the morning, and believing that a laceration of the urethra existed, sent for me. Upon examination, I found a considerable tumefaction and discoloration of

the perineum and scrotum; the bladder was distended, and bloody urine dribbled from the meatus. On straining, clear blood, followed by a little urine, was passed. The sound was arrested just opposite the pubes, coming in contact with a substance, which, at the time, was supposed to be bare bone. The patient was etherized, and a free incision made in the median line of the perineum, cutting through œdematous tissue until the urethra was reached. There was no extravasation of blood in the deeper tissues, nor could any laceration of the urethra be detected. The urethra was opened, a catheter passed, and the bladder emptied. The urine was discolored with blood. A probe passed upwards into the urethra, came in contact with a hard substance, which, when withdrawn by a pair of forceps, proved to be a rough calculus.

The symptoms which presented themselves on first seeing the case, together with the incomplete history, plainly indicated laceration of the urethra. A more careful study of the case, however, showed that as no blood followed immediately after the injury, but came on several hours later, while making some straining efforts to evacuate the contents of his bladder, it was plainly due to the passage of the calculus through the urethra, and not to the original injury. The patient made a good recovery, six weeks after the operation a good-sized instrument passing into the bladder without any obstruction.

On inquiry, I found that the boy had suffered from symptoms of stone, for nearly two years, but, considering the size and rough surface of the calculus, they were very slight.

CALCULUS REMOVED BY LITHOLAPAXY.

DR. LITTLE also presented a specimen of vesical calculus which he removed March 22d from a patient sixty-six years of age, who presented himself at the Post-graduate Medical School with symptoms of enlarged prostate and also stone in the bladder. On introducing a sound he touched a stone without difficulty. The patient was sent to St. Luke's Hospital, where he was etherized and Dr. Little made an attempt to seize the stone and crush it. After working for three-quarters of an hour, he touched it with the sound, but was unable to seize it with the lithotrite. The bladder was therefore washed out with Thiersch's boro-salicylic solution and further operative procedure discontinued. No bad symptoms followed the operation. Two weeks afterward he again etherized the patient, and after half an hour's manipulation came in contact with the stone, seized it, but could not retain it in the grasp of the instrument, and was unable to find it again. He then washed out the bladder with the same solution as before. No reaction followed, and the patient was much better after than before the operation. A week later he again tried to seize the stone, succeeded in catching it with a grasp of about three-quarters of an inch in diameter, crushed it, and after that broke up the separate fragments without difficulty, removing them with the evacuator. The patient made a good recovery. On examining the fragments he found that the stone was a round, flat one, and this was probably the reason why he failed to grasp it with the lithotrite at the previous operations.

CALCULUS REMOVED FROM THE BLADDER OF A WOMAN BY LITHOLAPAXY.

DR. LITTLE also presented fragments of a stone which he removed from the bladder of a woman, sixty-five years of age, accompanied by the following history furnished by Dr. William R. Larkin, acting house-surgeon to St. Vincent's Hospital.

Her father passed at frequent intervals small phosphatic calculi per urethram. The rest of the family were always very healthy. The patient states that she has always been healthy until two years ago, when she began to experience some difficulty in voiding her urine, especially in cold or inclement weather. The urine passed was slightly turbid, and gradually grew more and more cloudy. Twelve months ago she had acute retention, necessitating catheterization. Three months ago she had a second attack, which was relieved by the catheter, and since that date she has had her urine drawn at frequent intervals. Since her second acute attack of retention she has passed blood and an abundance of mucus. She states that when she first noticed the trouble caused by urination, two years ago, she had also frequent attacks of severe lancinating pain, especially marked and intensified on micturition. The pain was referred to the bladder, and radiated down the thighs to the knees, and had gradually increased in intensity so that the patient dreaded to pass her water. On admission to St. Vincent's Hospital the patient looked "careworn," face pale, pulse rapid, but strong, her appetite and general condition quite poor, and she suffered from loss of sleep. On examination, a vesical calculus, rather large and somewhat soft, was found. A day was appointed for its removal, but, in the meantime, a painful carbuncle appeared on the right buttock, in consequence of which the operation was postponed. On April 5th the patient was anæsthetized and litholapaxy successfully performed. No difficulty was found in seizing the stone. A short lithotrite (Thompson's) belonging to Dr. George A. Peters was used. This was much easier managed than the long instrument for the male bladder. A straight evacuating catheter, No. 29 French, was introduced, and the fragments removed by Bigelow's evacuator. Before introducing the catheter, the urethra was slightly dilated by means of Dr. S. D. Powell's four-bladed dilator. After the operation the bladder was thoroughly washed out with a solution of boro-salicylic acid, and the patient put to bed. The subsequent progress of the case was entirely favorable. Two weeks after the operation the patient left the Hospital, free from all symptoms, and having complete control over her bladder.

DR. KEYES said that he had, in several instances, experienced difficulty in attempting to pick up a small, flat stone with an instrument having the double curve of Bigelow. He thought it was impossible with the patient in position to pick up a small, flat piece of stone from the floor of the bladder with a lithotrite that has a double curve in cases in which the *bas-fond* of the bladder is deep and precipitous. He had had constructed an instrument without the extra curve in the female blade and in which the blades came very close together at the tip, with the female blade very thin, and with which he had been able to pick up a thin piece of stone from the floor of the bladder as well as from any other place. In

cases of very large prostate symmetrically developed, and a fairly large calculus, an instrument with the extra curve may be of some advantage.

DR. LITTLE said that the stone was finally seized with a Thompson's lithotrite without the double curve. He also stated that at the first two attempts he was unable to seize, or even to find the calculus. This case also illustrated what he had seen in several cases in which the patient was suffering from symptoms due to enlargement of the prostate as well as from stone, that the manipulations necessary to the operation of litholapaxy relieve the prostatic symptoms. In this case, the patient's symptoms were greatly improved by the attempts to find the stone. This, he thought, was explained by the dilatation of the urethra and the neck of the bladder, by the introduction of the evacuating catheters and the large lithotrite, and the thorough washing out of the bladder. In a case on which he operated last spring, at Woodstock, Vermont, the patient, a man, seventy-seven years of age, had enlarged prostate, and had been compelled to use the soft catheter every hour for nearly three months. Immediately after the stone was removed, which was a large one, measuring one inch and a quarter in diameter, he was able to hold his water for three hours, and on the third day he held it for six hours and passed it without the aid of a catheter. This condition lasted for over two months, the prostatic symptoms then reappeared, and the use of the catheter again became necessary.

DR. BRIDDON had seen two cases of impacted calculus in the urethra. The first occurred in his service in the New York Dispensary, and in a child two years old. The patient had symptoms of retention of urine, and the bladder was distended upwards to a point midway between the pubes and umbilicus. A catheter was introduced, and the sensation of passing over a foreign body was experienced in the deeper portion of the urethra, but the instrument entered the bladder and emptied it, and then came in contact with a stone. He appointed the following day for an operation, and the late Dr. Buck was present to assist. Dr. Briddon retracted the foreskin and discovered that there was a calculus in the urethra and it was removed. On introducing the staff into the bladder, another calculus was touched, and was removed by perineal incision.

The second case occurred in a child one year old, in his service in the Presbyterian Hospital, within the last year. Retention had occurred two or three times before admission, and when he saw the patient retention was quite pronounced. On the introduction of the catheter, a foreign body was found in the deeper urethra, but there was no difficulty in passing the instrument beyond the obstruction. In that case he cut the child on the following day, and removed a small calculus.

Dr. Briddon also referred to the case of a man in whose bladder he found a calculus with a cockspur projection, which he broke off with his finger, and after that was able to feel the remaining portion of the calculus in a sac in the bladder, but was unable readily to get it out. After considerable exertion with a small scoop, he succeeded in tilting the calculus out, which was about the size of a filbert. The man returned within the last two or three weeks to the Presbyterian Hospital with another calculus in the bladder. He performed litholapaxy, but had considerable difficulty in catching the stone. He was at work with the instrument in the bladder at least three-quarters of an hour, but no reaction whatever followed the operation.

SECONDARY HEMORRHAGE FOLLOWING FRACTURE WITHOUT INJURY TO THE ARTERY BY THE BONE.

DR. L. A. STIMSON reported a case of secondary hemorrhage following fracture without direct injury to the artery, occurring in the case of a man, twenty-five years of age, who was admitted to Bellevue Hospital about the middle of March with fracture of the right leg caused by being run over by a horse-car. The fracture was at the junction of the lower with the middle third, and there was considerable laceration of the integument upon the anterior portion of the leg. The bleeding at the time of his admission was slight. The wound was cleaned with the corrosive sublimate solution and thorough drainage adopted. On the eighth day after admission a profuse hemorrhage occurred, and the patient died a few hours afterward. At the autopsy, on exposing the anterior tibial artery, he found a ragged opening on its anterior surface one-third of an inch long, and situated an inch and a quarter above the line of fracture, and immediately above this large, ragged opening there was a small pin-hole opening; there was no clot in the vessel, the bone did not press upon it, and there was but little inflammation about it. The posterior tibial artery was thickened and discolored at the same level, and apparently undergoing an inflammatory process which might have terminated in thrombosis or ulceration, as the anterior vessel had done, if the patient had lived longer.

DR. MARKOE said that, at one time, he took pains to collect a number of cases of secondary hemorrhage after fracture, and in all of them, thirteen in number, he found the wound had been manifestly caused by the rubbing of the sharp edge of the bone, either of the fracture or of a necrosed portion, against the surface of the artery.

DR. STIMSON remarked that in his case there was no possibility of injury occurring from either of these causes.

FIBRO-SARCOMA OF THE KNEE-JOINT.

DR. MCBURNEY presented, in behalf of Dr. Weir, a small tumor which had been removed from the knee-joint, where it simulated a loose cartilage, and was attached by a long pedicle. The tumor measured one and a half by one inch. It was submitted to Dr. Peabody for microscopical examination, who made the following report:

"I have found no reason to change my mind regarding your knee-joint mass, and would only add that the spindle cells are so few in proportion to the fibrous tissue that I should suppose the prognosis would be rather that of a fibroma than of a sarcoma."

NEWS ITEMS.

GOVERNMENT QUARANTINES are now open at Ship Island, Miss., in the Gulf, and at Sapalo, off the coast of Georgia, the former under the charge of Surgeon Robert D. Murray, of the Marine-Hospital Service, and the latter under Acting Assistant Surgeon George H. Stone, stationed at Savannah, with Acting Assistant Surgeon

Brunner at the Station on Blackbeard Island, Sapalo Sound. The Cape Charles Quarantine Station, on Fisherman's Island, Chesapeake Bay, will be opened on the 15th instant, Passed Assistant Surgeon Fairfax Irwin, U. S. Marine-Hospital Service, in charge.

YELLOW FEVER AT RIO.—The yellow fever is on the increase at Rio; according to consular reports there were 28 deaths for the week ending March 15th, and 42 deaths from this disease for the week ending March 22d.

CHOLERA AT CALCUTTA.—Reports from Calcutta show an increase in cholera deaths, 51 having occurred during the week ending March 8th, and 95 deaths during the week ending March 15th.

THE HOMŒOPATHIC BILL before Congress, which is being pushed by its friends, has had several petitions presented in its favor during the past week; Senators Pendleton, of Ohio, Sawyer, of Wisconsin, Blair, of New Hampshire, and Colquitt, of Georgia, each presented petitions from citizens of their respective States, praying Congress for the passage of Senate bill 1223, making all qualified physicians equal before the law. For the benefit of our readers who may wish to know more about this bill, we herewith give its full text:

"S. 1223. A bill to secure to the medical profession equal rights in the service of the United States.

"*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,*

"That all appointments to medical service under the Government shall be made from graduates of legally chartered medical institutions, without discrimination in favor or against any school or theory of medical practice.

"Sec. 2. That any violation of the foregoing section shall be punished in the same manner as prescribed for like offences by the Act entitled, 'An Act to regulate and improve the civil service of the United States,' approved January sixteenth, eighteen hundred and eighty-three."

Read twice and referred to the Committee on Civil Service and Retrenchment.

ARMY MEDICAL OFFICERS.—The Senate has just passed a bill defining the title and duties of certain officers of the Medical Department of the Army. It prescribes that the six officers of that department having the rank of Colonel, shall be styled Assistant Surgeons-General; and the officers with the rank of Lieutenant-Colonel, shall be styled Deputy Surgeons-General. The rank and pay of all to remain as at present.

A COMPLIMENTARY DINNER TO PROF. ALFRED STILLÉ, M.D.—On behalf of the medical profession of Philadelphia, the following letter was addressed recently to Dr. Stillé:

DEAR DR. STILLÉ:

The undersigned members of the Medical Profession of Philadelphia, having learned with sincere regret that you are about to retire from the Chair of Medicine in the University of Pennsylvania, which you have adorned for so many years with so much honor to yourself, and so much credit to that venerable institution, and highly appreciating your dignified course as a professor, the valuable services which you have rendered to the progress of medical education and medical science, and your scholarly attainments as a writer, beg, as a fitting expression of their friendship and esteem, to tender you a public dinner, to be given at such time as may be most agreeable to yourself.

We have the honor to be, very truly, your friends,

(Signed), S. D. Gross, J. M. Da Costa, Albert H. Smith, D. Hayes Agnew, W. S. W. Ruschenberger, William Pepper, Roberts Bartholow, Samuel Lewis, Ellwood Wilson, James H. Hutchinson, J. Ewing Mears, J. H. Brinton, S. W. Gross, I. Minis Hays, R. A. Cleeman.

To this letter the following reply was received:

GENTLEMEN:

You have honored me with an invitation at once the most flattering to my professional pride and to my personal feelings that it was ever my good fortune to receive.

Some among you have had occasion to observe my public career, and others to judge of its quality and fruits. I may, therefore, well be proud of its receiving so cordial an approval from you, as well as grateful for the friendship of gentlemen who so conspicuously adorn the medical profession.

It will afford me great pleasure to meet you in the manner you propose, at any time that may be most convenient to yourselves.

I remain, with great respect, very sincerely yours,

ALFRED STILLÉ.

The dinner will be given at the Hotel Bellevue, on Thursday evening, May 22.

HARVARD UNIVERSITY.—Dr. Robert T. Edes has been appointed to fill the Chair of Clinical Medicine in Harvard University, made vacant by the death of Dr. Calvin Ellis.

GIFT TO BELLEVUE HOSPITAL MEDICAL COLLEGE.—Mr. Andrew Carnegie, one of the trustees of this school, has recently given the sum of fifty thousand dollars to the college, to be expended in the erection of a building, and in apparatus for laboratories for practical work and teaching in everything relating to microscopical and experimental research in the different departments of medicine. The building will belong to the Bellevue Hospital Medical College, but the advantages pertaining thereto will not be restricted to the students connected with the college; they will be open to students connected with other schools and to members of the medical profession throughout the country. It is believed that there is now no distinct building in this country on so large a scale as that which it is proposed to erect exclusively devoted to the same object.

CHICAGO MEDICAL COLLEGE.—Dr. W. W. Jaggard has just been elected Adjunct Professor of Obstetrics in this institution.

THE DWIGHT LIFE INSURANCE CASE.—We are requested to state that the Ætna Life Insurance Company of Hartford, which recently paid the amount of Col. Dwight's life insurance policy issued by them, was not a member of the combination of companies formed to contest the claim of the Dwight heirs. This combina-

tion, we are informed, is still firm in its determination to contest the claim.

PENNSYLVANIA HOSPITAL.—DR. D. HAYES AGNEW has recently resigned his position as Surgeon to this Hospital, and the vacancy has been filled by the election of DR. JOHN H. PACKARD.

SALE OF IMPURE ICE ILLEGAL IN CONNECTICUT.—The following bill, introduced by the State Board of Health of Connecticut, has been passed by both branches of the Legislature: "Any person who shall self, or offer to sell, for family or hotel use, any ice cut or taken from a pond or lake into which any sewer empties, or from such part of any river or other stream as is below and within two miles of the outlet of any sewer entering the same, shall be fined fifty dollars for each offence."—*Sanitary Engineer*, March 27, 1884.

ALABAMA STATE MEDICAL SOCIETY AND THE NEW CODE.—At the annnal meeting of the Alabama State Medical Association, held at Selma, on April 9th, the following resolutions, introduced by Dr. W. O. Baldwin, of Montgomery, were adopted:

Resolved, That the members of the Medical Association of the State of Alabama have watched with deep interest the progress of the struggle, which for the past two years has been going on in the New York State Medical Society, between the advocates of the ancient and established ethics of the medical profession, as embodied in the Code of Ethics of the American Medical Association, as heretofore recognized and observed by all physicians of reputable standing in all the countries of the civilized world on the one hand, and on the other hand the advocates of the so-called "New Code," or New York Code, which in effect proposes to degrade the medical profession by opening the way for professional association with irregulars and charlatans.

Resolved, That all hope of the prevalence of wise and conservative counsels in the New York State Medical Society having been dissipated by its action at its recent session in Albany, no honorable course was left for the adherents of the established ethics except that which they have chosen to pursue, namely, to separate themselves from the demoralizing movement which they were unable to control, and to organize themselves into a new Association for the maintenance of the honor and dignity of the profession in their State.

Resolved, That in doing this, these gentlemen, Flint, Jr., Gouley, Didama, Squib, Rochester, Flint, Sr., Sayre, Fox, and their associates have earned for themselves the thanks of the medical profession of the whole country, and we extend to them our congratulations and fraternal good will.

Resolved, That in order still further to signalize our appreciation of their recent action, a copy of these resolutions with the greetings of this Association be forwarded by our President to Dr. H. D. Didama, of Syracuse, the President-elect of the New York State Medical Association, wishing them prosperous fortunes and abundant success in the further development and fruition of their noble work.

Resolved, That a copy of these proceedings be also forwarded to THE MEDICAL NEWS, with a request that they be published.

DR. MORELL MACKENZIE'S NEW EDITION ON DISEASES OF THE THROAT AND NOSE.—A great fire recently occurred in the city of London, in which the premises of Messrs. Pardon & Sons, who have long been concerned with the printing of medical books and journals, suffered severely. Amongst other losses we learn that the entire edition of the long-promised second volume of Dr. Morell Mackenzie's work on *Diseases of the Throat and Nose* has been destroyed. Fortunately it will be possible to reprint the book from proof-sheets in the possession of the author, but the publication will necessarily be delayed for some months.

RECENT SANITARY LEGISLATION IN NEW JERSEY.—The Legislature of New Jersey has given increased powers to local Boards of Health by permitting them to pass ordinances for the following purposes:

To regulate and control the method of construction, the location, the method or manner of emptying and the time or frequency of cleansing of all cesspools and privy-vaults; to regulate house drainage and connection with sewers and cesspools; to protect the public water supply and to prevent the pollution of the same, and to close any well the water of which is dangerous to health; to remove to a suitable place persons sick with any contagious disease; to regulate the burial and disinterment of human bodies. These powers are in addition to those already given by the law of 1882.

OBITUARY RECORD.—WILLIARD PARKER, M.D., LL.D., died at his residence in New York City, on Friday, April 26th. For more than a year he had suffered from pyelitis. On April 13th he had a stroke of paralysis with aphasia, and his death was not unexpected.

Dr. Parker was born in Hillsboro, N. H., on September 2, 1800. On both sides he was descended from English Puritan blood. Being the oldest child of his parents, much of his time was spent working on the farm until he was nineteen years of age, thus giving him an amount of physical vigor which has stood him in good stead for many years. While thus working he was reading and studying in his leisure, and he prepared himself to teach school, which he commenced on leaving the farm at nineteen. At the same time he prepared himself for college, and entered Harvard University, from which he graduated in 1826. During his first year at Harvard an incident occurred which turned his attention to surgery. His chum happened to have a strangulated hernia, which the surgeon of the town was unable to reduce. Dr. John C. Warren, then Professor of Surgery in Harvard, was called in, and his facility in diagnosticating and reducing it so impressed young Parker that he immediately resolved to study medicine. On graduating from Harvard he entered the offices of Drs. Warren and Townsend as a medical student. In the spring of 1827 he received the appointment of House Physician in the U. S. Marine Hospital, at Chelsea, where he remained about two years. In the winter of 1828–9 he became the private pupil of Dr. John C. Warren, whose lectures he had attended for two years, The office of House Surgeon having been just created in the Massachusetts General Hospital, the position was offered to young Parker, who accepted it, serving for about a year, and attending lectures at the same

time. In February, 1830, he received his degree of Doctor in Medicine. Previous to his graduation he delivered, during the summer of 1829, a course of lectures upon anatomy in the Medical School at Woodstock, Vt. In June, 1830, he was appointed to the Chair of Anatomy in the Berkshire Medical School, at Pittsfield, Mass., while he continued his lectures at the Woodstock School. In 1832, a vacancy having occurred in the Chair of Surgery in the Pittsfield School, Dr. Parker was appointed to it, thus delivering two lectures daily. In 1836 he accepted the Chair of Surgery in the Cincinnati Medical College, but soon afterwards went abroad and spent some time in the English and French Hospitals. Returning to America he intended to make Cincinnati his home, but was compelled to leave the West on account of the injurious effect of the climate upon his health. In 1839 he received the appointment to the Chair of Surgery in the College of Physicians and Surgeons, New York City, and it was this appointment which enabled him to initiate the system of college clinics in America. Appreciating the want of practical demonstration in teaching surgery, and holding at the time no hospital position, he visited, with the students, two of the city dispensaries. Soon afterwards interesting cases were selected and taken from the dispensaries to the college, where, in the amphitheatre, superior advantages were offered for making diagnoses and performing operations before the class.

In 1845, the City Almshouse, now Bellevue Hospital, was reorganized under a board of governors, and Dr. Parker and the late Dr. James R. Wood were appointed visiting surgeons. Ten years afterwards, in 1856, he was appointed visiting surgeon to the New York Hospital. During these ten years his abilities as a daring and skilful, yet conservative and prudent surgeon, and his wisdom and foresight in diagnosis, had become rapidly recognized. In 1865, on the death of Dr. Valentine Mott, the President of the State Inebriate Asylum at Binghamton, Dr. Parker was appointed his successor, and to this institution he devoted much time and thought. In 1870, he resigned his Chair in the College of Physicians and Surgeons, becoming Emeritus Professor of Surgery; and in the same year he received the degree of LL.D. from Princeton College.

Although Dr. Parker's professional work was not in any special field of medicine, he had his preferences. On one occasion, being asked what these were, he replied:

"Medical treatment and diagnosis as associated with surgical cases. If a man does not familiarize himself with different remedies and their applicability to certain special disorders resulting from surgical cases, he degenerates into nothing more or less than a butcher. It is the glory of the profession to save a limb. But that which I particularly regard as beautiful in its results and satisfactory in its issues is the cutting down for and ligating arteries."

He was the first to point out the distinction between "Concussion of Nerves" and "Concussion of Nerve-Centres." Among his contributions to surgery are cystotomy for chronic cystitis, and the operation for abscess of the appendix vermiformis. His operation for the relief of laceration of the perineum through the sphincter was an important contribution to the surgery of this affection. He ligated the subclavian artery five times, and was the first, in America, to ligate the common carotid and vertebral arteries, in this operation, to prevent hemorrhage by anastomosis.

As a teacher, Dr. Parker had a high reputation and marked success. With a fine personal presence, and a courteous and affable manner he won the personal regard of his pupils, and at the same time riveted their attention by his lucid style and by the simple, commonsense character of his operations and general treatment. Dr. Parker left no works on medicine; the reports of his cases even were made by others. His time was so fully occupied with his lectures and the demands of an immense private practice, that he found no time for writing.

He was consulting surgeon to the New York, Bellevue, St. Luke's, Roosevelt, and Mount Sinai Hospitals, and to the Home for Ruptured and Crippled. He leaves a wife, a son, Dr. Willard Parker, Jr., and two daughters.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending April 19, 1884, indicate that inflammation of the brain, pneumonia, and erysipelas have increased, and that remittent fever, diarrhœa, and intermittent fever have decreased in area of prevalence.

Including reports by regular observers and others, diphtheria was reported present during the week ending April 19, and since, at eight places, scarlet fever at twenty-three places, and measles at seven places.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 22 TO APRIL 28, 1884.

PORTER, JOSEPH Y., *Captain and Assistant Surgeon.*—Granted leave of absence for two months, to take affect about May 5, 1884.—*Par. S. O. 38, Headquarters Division of the Missouri*, April 19, 1884.

BIART, VICTOR, *Captain and Assistant Surgeon.*—Granted leave of absence for one year on surgeon's certificate of disability, with permission to leave the Division of the Missouri.—*Par. 2, S. O. 91, A. G. O.*, April 19, 1884.

LA GARDE, LOUIS A., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, with permission to apply for two months' extension.—*Par. 1, S. O. 91, A. G. O.*, April 19, 1884.

NEWTON, R. C., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Sill, Indian Territory, and ordered to Fort Elliott, Texas, for duty.—*Par. 1, S. O. 77, Headquarters Department of the Missouri*, April 14, 1884.

CHAPIN, ALONZO R., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Douglas, Utah, and ordered to Fort Laramie, Wyoming, for duty.—*Par. 2, S. O. 33, Headquarters Department of the Platte*, April 15, 1884.

COFF, JOHN VAN R., *Captain and Assistant Surgeon.*—To be relieved from duty at Alcatraz Island, California, and to report to the Commanding Officer at Fort Mason, California, for duty as Post Surgeon.—*Par. 3, S. O. 45, Headquarters Department of California*, April 16, 1884.

BARROWS, C. C., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Grant, A. T., and ordered to report for duty at Whipple Barracks, A. T., relieving First Lieutenant W. E. Hopkins, Assistant Surgeon, who, upon being relieved, will report for duty as Post Surgeon at Fort Grant, A. T.—*Par. 1, S. O. 31, Headquarters Department of Arizona*, April 21, 1884.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLIV. SATURDAY, MAY 10, 1884. No. 19.

AMERICAN MEDICAL ASSOCIATION.

THIRTY-FIFTH ANNUAL MEETING, WASHINGTON, 1884.

THE PRESIDENT'S ADDRESS.

Delivered May 6, 1884.

BY AUSTIN FLINT, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

GENTLEMEN: The American Medical Association has reached an age when the thoughts of one whose retrospections extend to its birth naturally revert to the natal period of its existence. Of those who coöperated in the formation of the Association, not many now remain, and after a few more annual meetings all will have passed away.

Thirty-eight years ago, a medical convention was held in the city of New York, in compliance with a recommendation by the Medical Society of the State of New York in 1845. In 1839, the Medical Society of the State of New York adopted a resolution recommending a national convention to be held in Philadelphia in 1840. This action of the Society was without effect. In connection with the recommendatory resolution adopted in 1845, a committee of three was appointed to carry the resolution into effect, and the mover of the resolution, Dr. N. S. Davis, was made chairman of that committee. Thanks to his zeal and energy, at the time and place designated by the Medical Society of the State of New York, the convention was held, and attended by about one hundred delegates, representing medical colleges and societies in sixteen States of the Union. I can bear testimony, from personal recollection, to the enthusiasm which characterized that convention. The convention resolved that it was expedient to form a national medical association, and a committee of seven was appointed to report a plan of organization at a second convention, to be held in Philadelphia, in May, 1847. A committee of seven was appointed to report, at the same time and place, a uniform and elevated standard of requirements for the degree of M.D.; another committee of seven was appointed to report on a suitable preliminary education for the study of medicine; and a committee of seven was appointed to report a code of medical ethics.

At the convention held in Philadelphia in May, 1847, there were present two hundred and fifty delegates—forty medical societies, twenty-eight medical colleges, twenty-two States of the Union, and the District of Columbia being represented. I can testify to an enthusiasm even greater than at the first convention. Resolutions reported by the several committees appointed at the New York convention were adopted. These resolutions embraced a plan of organization, a constitution, and by-laws, together with the now existing code of medical ethics, and the convention was merged into the American Medical Association. Thus, the birth of the Association was in 1847, and it therefore now enters upon the thirty-eighth year of its existence.[1]

What motives led to the formation of the Association? First, and most prominent, was a desire to promote improvements in medical instruction, and to advance the standard of professional acquirements. These were the aims stated in the call for the first convention. A more comprehensive statement was expressed in the first of a series of resolutions prepared by Alfred Stillé, and offered by Isaac Hays, as follows: "It is expedient for the Medical Profession of the United States to institute a National Medical Association, for the protection of their interests, for the maintenance of their honor and respectability, for the advancement of their knowledge, and the extension of their usefulness." It had become evident that for the ends expressed in this resolution the profession in this country must rely mainly on itself. Little was to be expected from State Legislatures. These bodies then, as now, were indisposed to legislate in behalf of medical education, except to charter new colleges; they were even reluctant to legalize dissections; they had not then, nor have they since the formation of the Association, recognized the promotion and diffusion of medical knowledge as legitimate objects for ample appropriations of public funds. As a rule, so far as legalized protection, sanction, and encouragement go, they have been not less considerate of irregular than of regular medical practice; and, indeed, the terms regular and irregular denote a purely professional, not a legal, distinction. The State of New York, at the time of the first convention, had, virtually, admitted the right of any one to practise medicine; in few, if any, of the States of the Union were there legal restrictions, and in some there were no laws whatever relating to medical practitioners. Nor was much to be expected then, as now, from individuals outside of the profession. Liberality, philanthropy, and public spirit had not, and as yet have not, except in rare instances, taken a direction towards medical instruction and the advancement of medical knowledge. A conviction of the necessity for self-reliance, and a deep sense of the importance of the ends set forth in the resolution which I have quoted—these were the mainsprings in the movement which resulted in the organization of the American Medical Association. The need for uniting in council members of the profession from all parts of the country was widely felt. The feeling was catholic, not sectional. The ends had reference, not to a single State, but to the United States. When Davis introduced his resolutions at the meeting of the Medical Society of the State of New York, in 1845, the "fulness of the time had come," and, in the providential order of human

[1] The annual meetings were suspended from 1860 to 1863, that is, for the years 1861 and 1862. The suspension of the meetings for these two years was owing to the civil war. It is worthy of note that the Medical Society of the State of New York, in February, 1863, adopted unanimously a resolution in favor of resuming the regular annual meetings of the Association.

events, the American Medical Association came into existence. Its development and growth were rapid. It has now passed through a healthful adolescence into a mature age. It has outlived, and profited by, the errors and imperfections incident to youth. We have before us to-day the proof that it is replete with vitality and vigor.

I have not indulged in these reminiscences of the origin of the Association with an intention to review its subsequent history. As furnishing appropriate topics for my discourse on this occasion, I take for my text the preamble to the plan of organization adopted at the formation of the Association. This preamble is as follows:

"Whereas, the medical convention held in the City of New York in May, 1846, have declared it expedient for the medical profession of the United States to institute a National Medical Association, and inasmuch as an institution so conducted as to give frequent united and emphatic expression to the views and aims of the medical profession in this country, must at all times have a beneficial influence, and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor, and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it; therefore, be it resolved, in behalf of the medical profession of the United States, that the members of the Medical Convention held in Philadelphia in May, 1847, and all others who, in pursuit of the objects above mentioned, are to unite with, or succeed them, constitute a National Medical Association."

The objects of the Association are here clearly and tersely set forth. My remarks will have reference to these objects. The topics which in connection therewith suggest themselves, are so many and large that, with a due regard to the length of my discourse, not a few must be omitted, and none can be fully considered.

The terms "cultivating and advancing medical knowledge," by which the first object is expressed in the preamble, imply that medicine is progressive. No one of those whom I address will deny the assertion that medicine is now progressing, as it has progressed in the past, and that it will continue to progress in the future. I do not doubt that the present stage of its progress will hereafter be cited as an important epoch in its history. For the past quarter of a century, histological and clinical studies have tended to develop more and more our knowledge of the existence of specific agents in the causation of diseases. That, as regards certain diseases, these specific agents are microörganisms, has been demonstrated. The latest discovery in this direction is that of the bacillus tuberculosis, a discovery which is the leading topic in medical literature at the present time. Recent trustworthy researches go far toward demonstrating the existence of specific organisms in pneumonia, typhoid fever, malarial fever, and epidemic cholera; and, reasoning by analogy, it is a logical conclusion that ere long a host of diseases will be proven to be parasitic. It is easy to perceive how important must be the bearings of these developments in etiology and pathology on prophylaxis and therapeutics.

A new era is about to be inaugurated in these practical departments of medicine. Prof. Huxley, in his address at the International Medical Congress in 1881, uttered a prediction in these words: "It will become possible to introduce into the economy a molecular mechanism which, like a very cunningly contrived torpedo, shall find its way to some particular group of living elements and cause an explosion among them, leaving the rest untouched." I would rather say that the time will come when means will be found to destroy morbific agents outside of the body, thereby securing the prevention of diseases; and that means will be found to effect the destruction of these agents within the body, thereby arresting the course of diseases. Let us hope that the medical profession in this country will take an honorable part in labors for the cultivation and advancement of medical knowledge with reference to these most desirable results! At all events, let us continue to recognize and apply medical knowledge wherever it may originate!

"For elevating the standard of medical education;" these terms express the second of the objects enumerated in the preamble. At the first convention, held in 1846, a committee was appointed to report on "a uniform and elevated standard of requirements for the degree of M.D., to be adopted by all the medical schools in the United States." Another committee at the same convention was appointed to report on the "standard of acquirements which should be expected of young men before being received as students of medicine." These committees, at the second convention, in 1847, submitted reports which were adopted. Now, it has been charged upon the Association that its recommendations in regard to medical education have been nugatory. If, however, the recommendations embraced in these reports be referred to, it will be seen that there is less room for reproach than some may have supposed.

The committee on the requirements for the degree of M.D. reported, in substance, as follows: That the college terms be extended from four to six months; that candidates for the degree of M.D. shall have attended two full courses of lectures before graduation; that three years should be devoted to the study of medicine; that a certificate of pupilage by a preceptor who is avowedly and notoriously an irregular practitioner should not be accepted; that the number of professors in medical schools be increased to seven; that candidates shall have devoted three months to dissections; that preceptors should avail themselves of every opportunity to impart clinical instruction to their pupils.

It would be absurd for the Association to renew these recommendations at the present time. The progressive advancement in medical instruction in most of our colleges has long since gone far beyond them. It is not to be doubted that the Association exerted not an inconsiderable influence in the progress which has been made in medical instruction. That there is room for further advancement, no one will deny, and it is certain that it will continue in the future as in the past, albeit not, perhaps, with a celerity to satisfy those who seem to derive gratification from the disparagement of medical education in this country. Improvements which, al-

though steadily progressing, are to be promoted, relate to a closer union of didactic with clinical teaching, and especially to practical exercises in the investigation of cases of disease; to increased demonstrative instruction in special branches of medicine, such as histology, the microscopical and chemical examinations of morbid products, together with the fluids of the body in health as well as in disease, the physical exploration of the lungs, heart, and other organs, etc.; to a larger allowance of time in connection with oral teaching for recitations; to the substitution of recitations, to a greater or less extent, for didactic lectures in certain departments, and to an extension of the period of medical pupilage.

The educational advantages, exclusive of those relating to college sessions, although vastly better now than heretofore, may be much extended and made more available than at present. The pupils who, between college sessions, study in the offices of medical practitioners in the country, reading such books as they find in the meagre, and perhaps antiquated libraries of their preceptors, accompanying the latter in their "rides," preparing medicines and making themselves generally useful, may undoubtedly pick up many facts and ideas which will become useful in after-life, but it hardly requires argument to show that systematic private instruction is much to be preferred. Moreover, methodical reading and recitations are essential, not only for the information thereby obtained, but in order that the pupil may acquire, if it have not been already acquired, what may be called the art of study. There are those who, having obtained their medical education chiefly from oral teaching and demonstrations, cannot apply the mind to study by means of books, although not indifferent to the knowledge to be thus obtained, for the simple reason that they lack the ability to be acquired only by practical training.

At the present time the most important of the means for elevating the standard of medical education relate to the preliminary requisites for the study of medicine. The committee appointed in 1846 to report on this subject, recommended that members of the medical profession throughout the United States should satisfy themselves before receiving young men as students, that they have acquired "a good education, a knowledge of natural philosophy, and the elementary mathematical sciences, including geometry and algebra, and such an acquaintance, at least, with the Latin and Greek languages as will enable them to appreciate the technical language of medicine, and read and write prescriptions." It was also recommended that the medical colleges require a certificate of such an amount of preliminary acquirements before matriculation.

These requisites are, assuredly, neither in number nor degree, unreasonable. The need of any knowledge of the dead languages has been doubted, but when it is considered that the names of all the organs and tissues in the body, and the nomenclature of diseases, together with the terms used in physiology, chemistry, materia medica, pharmacy, surgery, and obstetrics, are of either Greek or Latin derivation, it is difficult to understand how the student can dispense altogether with this knowledge. The want of it must, to say the least, be a great drawback. A thorough acquaintance with these languages, philologically, or with reference to the appreciation of the literature of Greece and Rome, however elegant as an accomplishment, is by no means essential as preparatory for the study of medicine, and it may fairly be questioned whether the time usually spent in the study of the Greek and Latin authors by those who graduate in arts at our colleges, might not be given with much more profit to physics, chemistry, and the French and German languages. To the requisites recommended by the Association, might be added, with advantage, knowledge of the elements of chemistry, leaving only the practical application of this science in the different departments of medicine to be taught in our medical schools.

It must be confessed that the progress in the matter of the preliminary education of medical students, is less satisfactory than that in medical instruction. Not a few medical students are deficient in the knowledge and the mental training requisite as preparatory for the study of medicine. The fault, exclusive of the students themselves, lies in part with the medical schools, and partly with private preceptors—more with the latter, inasmuch as to them generally applications are first made to enter upon the study. I have no wish to be an apologist for either; there is blame on both sides, and there should be mutual coöperation in an effort to remove the greatest of the present obstacles in the way of elevating the standard of medical education.

The practical question is, what can the Association do to promote more and more the elevation of the standard of medical education? I will meet this question, in the first place, by suggesting what it is desirable should not be done.

It is not judicious to decry medical instruction in this country as unworthy of any commendation, and as contemptible when contrasted with the educational advantages of other countries. The low estimate in which medical education in America appears to be held by some of our writers, is not only discouraging, but it is without any warrant from facts. Our methods of teaching have certain notable advantages above those of other countries; and in respect of effectiveness in practical branches, we have no occasion to be ashamed if comparisons be fairly made.

It is alike impolitic and unjust to depreciate, as is sometimes done in offensive terms, the medical profession of the United States. As a body, the members of our profession in this country are neither ignorant nor in any respect unworthy. The profession is honorable and honored. In no other country is the social status of its members higher. If a distinction be not always drawn, in public estimation, between true merit and either pretentious ignorance or fraudulent assumption, this is an evil by no means confined to our country; it is incident to the peculiar character of medical knowledge and to human credulity. Granting the need of a better average of professional acquirements, it is not to be effected by abuse of the profession as a whole.

Sweeping charges against medical schools of venality and deception, are not less unwise than unbecoming. As regards their maintenance, the condition of the medical schools in this country, when compared with those of other countries, is anomalous. For the most part they are unendowed, and, therefore, must be self-sustaining. If they cannot offer adequate inducements for patronage, they cannot exist. This condition has its advantages, but also its drawbacks. There is but little

ground for the accusation of resorting to dishonorable methods to secure patronage. I may venture to assume some degree of competency to speak with confidence in regard to this matter, it having fallen to my lot to have been connected with several medical colleges, and I aver my belief that the endeavor to entice students by an expectation of easy graduation, or by any other disreputable inducements, must be rare exceptions to the rule. Granting that there are exceptions, and that some colleges may be guilty of flagrant abuses of their chartered rights, is it not more just, and in all respects better, to pursue measures for the extinction of their rights, or for rendering their degrees nugatory, than to make the evil doings of a few, the ground for indiscriminate abuse, embracing colleges which are striving to do their duty to their pupils, to the medical profession, and to the public?

It is injurious and an injustice to assert, as is often done, that a large proportion of those pursuing the study of medicine in this country are governed by a desire to gain admission to the profession as quickly, as cheaply, and with as little medical knowledge as will suffice for that object. Here it may not be too presuming in me to speak with some authority, having, as a teacher for forty years, been brought into relations with many thousand medical students, from the northern, southern, eastern, and western States of the Union. As a class, they will compare favorably with those preparing for the sister professions, or for any of the callings of life. A large proportion evince a degree of diligence and perseverance not excelled, as I believe, in any other country. I rejoice in the present opportunity to bear this testimony, based on personal knowledge, in behalf of the much and undeservedly abused American medical students.

Elevation of the standard of medical education is not to be promoted by means such as have just been adverted to. Vituperation does not supply motives for improvement. Reforms are not favored by obloquy. He who is content to do battle with the sword of ridicule has not the spirit of a true reformer. I have no disposition to deny or to take the attitude of an apologist for defects and abuses which affect, directly or indirectly, the standard of medical education. Some of the evils most complained of might be obviated by the united action of the members of the medical profession. Much is said respecting the overcrowding of the profession by the large number of annual graduates, and this evil is attributed to the number of medical colleges. Assuming, for the nonce, the fact together with the explanation, and that the evils overbalance the advantages of an active competition among the colleges, how is the number of these to be reduced? Reliance on State legislation would be delusive. Legislators are not likely to take away charters which have been granted, and they will probably continue to be complaisant enough to grant new charters to persistent applicants. But suppose all private perceptors were to induce their pupils not to connect themselves with colleges which are either misplaced or deficient in the means of instruction; a certain number would cease to exist, and the result would exemplify the Darwinian doctrine of the "survival of the fittest."

Again, suppose private perceptors throughout the United States were to unite in declining either to receive as pupils or to advise entering on the study of medicine all who lack the proper requirements; the evil of the deficiency in preliminary education would be at once removed.

I revert to the question, "What can our Association do to promote more and more the elevation of the standard of medical education?" It is to be borne in mind that, exclusive of the motives for personal improvement which appeal to its members individually, the profession must rely upon itself for whatever is to be done. The American Medical Association represents the profession of the whole country. Hitherto the Association has been content with reports, addresses, and communications pointing out existing defects in medical education, and recommending changes and improvements, the immediate adoption of some of which was impracticable. Too often a predominant spirit of animadversion has been apparent. Let a course be pursued which is more active and practical, with reference to measures for progress. Let certain measures be proposed for immediate adoption, which are within the limits of practicability. Let these measures receive the sanction and support of local Associations in the different States of the Union. Let the National Association take the initial steps, and solicit conferences with and the cooperation of State Associations and the leading medical colleges throughout the country, with a view to agreement respecting the proposed definite measures. Let these steps be taken in a kindly spirit with an earnest desire to harmonize different views and interests, in order that there may be united action as regards improvements agreed upon. In this way, as we may hope, uniformity in the different States will be secured in behalf of the second of the objects for which our Association was instituted. There can be but little difference of opinion as to the improvements in medical education which it is desirable should be effected; the opposing difficulties are chiefly those which interfere with uniformity throughout the United States. I venture to suggest the appointment of a standing committee on medical education with a view especially, by means of communications with State associations and colleges, to secure uniform action with reference to requirements for matriculation and for graduation. My purpose in the suggestion of such a committee, is not to obtain reiterated resolutions setting forth what ought to be done, but reports at the next meeting, and at subsequent meetings of the Association, of what has been actually accomplished. It is not to be expected that all desirable improvements will be at once effected. Considering the greater relative importance of preliminary requisites for the study of medicine, were these made the first objective point in the action of the committee with a satisfactory result, a very important advance would be made, and this would be likely to prove an earnest success in effecting other improvements.

A plan for the elevation of the standard of medical education, which has been recommended by the Association, consists in making the degree of M.D. purely an honorary distinction, not rendering the graduate thereby legally qualified to practise, this qualification to be derived from a licensing board, composed of examiners not engaged in medical teaching. Of this plan, I forego discussion, for the reason that it would exclude the consideration of topics which seem to me more im-

portant. With no disposition to undervalue its recommendations, I will simply remark that, aside from certain intrinsic objectionable features, it is open to objection on the ground of the impracticability of securing uniformity in the different States of the Union, and because it contravenes the principle of self-reliance in matters relating to our profession.

In the language of the preamble, the third object of our Association is "for promoting the usefulness, honor, and interests of the medical profession." I shall confine my remarks on this object to a topic which is, perhaps, at the present time, the most important bearing upon it. I refer to medical ethics. I need not undertake to represent to this audience how manifold, delicate, and peculiar are the professional duties and relations of the medical practitioner. There is no other calling in which so much depends on the conscientiousness and uprightness of those who practise it. There is no calling in which the temptations and opportunities for deviations from rectitude are so great. In the enumeration of the attributes of the physician by Hippocrates, with "learning and sagacity" were conjoined "humanity and probity."

In order to practise medicine with proper self-respect, the practitioner himself must honor the profession, and in order that medical services shall be properly respected, the profession must be honored in public estimation. The duties incident to medical practice are often of a nature to render them menial and degrading were they not required by a humane and honorable calling. Some one has said with truth that, while medicine is a noble profession, it is the meanest of trades. Imbued with these sentiments, the founders of our Association, at the convention in 1846, resolved, "That it is expedient that the medical profession in the United States should be governed by the same code of medical ethics, and that a committee of seven be appointed to report a code for that purpose." A committee appointed in accordance with this resolution reported a code of ethics at the convention held in Philadelphia in 1847. This code was adopted by the American Medical Association without a dissenting voice. It has remained essentially intact up to the present time, and it has been adopted by medical societies throughout the United States.

It were gratuitous to expatiate on the excellence of this code. It speaks for itself better than any one can speak in its behalf. It has exerted a most salutary influence on the minds of the members of the medical profession in this country. It has promoted love of the profession, and self-respect as members of it, thereby contributing to its usefulness, its honor, and its true interests. I believe that a former President of this Association, Dr. N. S. Davis, uttered a correct statement in saying that in no other country are the principles and rules of medical ethics better observed than by the majority of the members of the profession in the United States.[1] And it is a reasonable conclusion that this is owing in a great measure to the influence of the National Code on the minds of the practitioners of medicine in our country. I concur with the speaker who addressed the Association from this chair in 1882—Dr. Hooper—in the opinion that the American Medical Association, had it done nothing else than to adopt the Code of Ethics, would have been entitled to unending gratitude. I cannot forbear quoting some extracts from the address of a distinguished predecessor, the late Prof. George B. Wood, in 1856: "A great benefit conferred on the profession by the Association was the preparation and adoption of the Code of Ethics. . . . I have no doubt that a full observance of its rules would tend more than any one thing else to maintain harmony in the profession, and to elevate it in the public esteem. . . . I do honestly believe that to a young physician going forth into a life full of moral conflicts, the wearing of this ægis would be one of his surest defences; that, next to the holy Scriptures and the grace of God, it would serve most effectually to guard him from evil."

It is only within a recent period that there have been, anywhere, manifestations of a disposition to change materially our national Code of Ethics, or to do away with any code. In 1882, at the annual meeting of the New York State Medical Society, by a vote of fifty-two of seventy members in attendance at the meeting, a new code was summarily substituted for the code of the American Medical Association. This precipitate and lamentable action has severed the New York State Society from its affiliation with our Association, and has resulted in a division of the members of the profession in the State of New York. That these results may not be permanent must be the fervent wish of all who have at heart the usefulness, honor, and interests of the medical profession.

Some of the recent opponents of our National Code object to it as antiquated, quaint, and containing useless platitudes. These objections do not call for serious refutation. They involve merely a question of taste; and the characteristics which by some are considered as blemishes, have for others a peculiar charm. Admitting that certain of the precepts of the Code are supererogatory, no one can object to them on the ground that they do harm; and if they be acceptable even to a few, wherefore should they be opposed by any?

Other objections are, that the Code has, to a greater or less extent, proved inoperative, and that its rules are not enforced by means of penalties for the non-observance of them. The Code itself contains nothing in regard to penalties, nor do the By-Laws of the Association take cognizance of these except to exclude from representation local societies which have not adopted the Code, or "which have intentionally violated or disregarded any of its articles or clauses." With this exception, the enforcement of ethical rules is left entirely to local societies. The fault, if fault there be, lies at the doors of the latter. But granting the fault to be ever so great and widely extended, is this a valid reason for formally repudiating obligations which are morally binding? Are the principles of morality pertaining to any of the duties of life to be ignored because immorality prevails? Are penal laws to be erased from the statute-book because punishment often does not follow crime? Although few, if any, live up to the Scriptural injunction to "do unto others as you would that they should do unto you," is this quintessence of religious duty to be expunged from Holy Writ? It is the salutary influence on the minds of members of the profession, in which consists the greatest potency of the

[1] Address at the Convention of Medical Editors, 1883.

ethical code for good, and I will go so far as to say that the Code were invaluable were no penalties incurred by violations of it beyond those pertaining to the conscience of offenders.

The portion of the Code which is especially objected to is that relating to consultations with irregular practitioners. The advocates of the New Code, so called, in the State of New York, would permit consultation with all legally qualified practitioners of medicine. The advocates of "No Code" would leave it entirely to individual judgment to decide with whom members of the medical profession should meet in consultation. After quoting the portion of the Code relating to this topic, I will ask your consideration of the views which I shall offer. The following is the article of the Code referred to:

"A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner who has a license to practise from some medical Board of known and acknowledged respectability, recognized by this Association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation when it is requested by the patient. But no one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

The excluding clause which is the last sentence, specifies who is not to be considered as a regular practitioner. No one surely will deny that a practitioner such as is specified in that clause, cannot be considered as a regular practitioner. The article does not assume to embrace a comprehensive definition of irregular practitioners. At the time when the Code of Ethics was adopted, the great majority of irregular practitioners were men who not only based their practice on an exclusive dogma, but made no concealment of their rejection of the "aids actually furnished by anatomy, physiology, pathology, and animal chemistry." They made no pretension to knowledge of these branches of medicine, and they scornfully repudiated the "accumulated experience of the profession." The language of the article, which applied well enough to most of the irregular practitioners at that time, is not as applicable to those of a later date. It is not affirmed in the wording of the Code, that holding an exclusive dogma is, in itself, sufficient for a practitioner to be considered as irregular. The language which refers to an exclusive dogma, is to be taken in connection with the remainder of the same sentence. Exclusive dogmas have prevailed, to a greater or less extent, in past time, among members of the regular medical profession. Legitimate medicine places no restrictions on individual opinions; it does not assume to interfere with the utmost freedom in this regard. What is it then, irrespective of a "rejection of the accumulated experience of the profession and the aids actually furnished by anatomy, physiology, pathology, and organic chemistry," which stamps irregular practitioners? Is it not the assumption of a distinctive name, such as homœopathist, eclectic, botanic, etc., voluntarily assumed as an announcement to the public of the adoption of a system of medicine, distinct from, and opposed to the practice of the regular profession, and on this distinction and opposition basing their claims as practitioners?

In order to make my meaning clear, let me illustrate it by examples. Within the recollection of those who have been in the profession for more than half a century, there prevailed simultaneously, for a time, two dogmas quite opposite in character, each having its ardent partisans. I refer to Broussaism and Brownism. Broussais and Brown were men of genius and learning, led astray by specious theories. They were honest in their opinions, and they sought to convince members of the profession, not the public, of the truth of their dogmas. Their partisans were often called Broussaists and Brunonians; but they never assumed these names as sectarian designations. Now, had they assumed these names, making themselves known to the public as practising Broussaism or Brownism, and on this ground basing their claims for practice, they would have been irregular practitioners not entitled to professional fellowship. As it was, they were not without the pale of the regular profession.

As a hypothetical example, *per contra*, suppose a graduate from a medical college of acknowledged respectability, whose professional attainments are sufficient to qualify him for membership of the regular profession, has adopted a sectarian name and allied himself with those who profess antagonism to legitimate medicine. He is, therefore, an irregular practitioner whatever may be the particular tenet which is ostensibly the basis of his practice. Let it be supposed that such a practitioner is desirous of being enrolled in the ranks of the regular profession. I need not say that this profession has no creed, no articles of faith, no traditional doctrines which it imposes as conditions for membership. It enjoins no limitations of private opinions, it matters not how fantastic. In order that such an irregular practitioner as has been represented may enter the regular profession, no relinquishment of honest convictions is essential. In addition to educational and moral qualifications, the renouncement of a sectarian designation, of the hostility to the profession thereby involved, and conformity to the rules of medical ethics, are alone necessary. It is a calumny to say that persons are excluded from the medical profession on account of peculiar views, however irrational, and that conversion and recantation are essential for professional fellowship. The doors are closed to no one who has received a regular medical education, and whose conduct is governed by the rules of medical ethics.

It might prove a hazardous experiment to tamper with a Code of Ethics so complete and perfect as our National Code, and which has stood so well the test of time. Daniel Webster was accustomed to stigmatize efforts to amend the Constitution of the United States, as attempts to "tinker the Constitution." This pithy saying might be applied to propositions for altering our ethical code. But it is safe and reasonable for interpretations of the Code to be authorized from time to time, in adaptation to circumstances as they arise; and I

submit, as a recommendation, that the Association adopt resolutions embodying a more precise specification than the Code furnishes, of the grounds for refusing fellowship with irregular practitioners. This recommendation is in accordance with precedents. At the annual meeting in 1869, the Association adopted a resolution which recognized "specialties as proper and legitimate fields of practice." Herein was an authorized interpretation of the Code in adaptation to new circumstances. It was also resolved not to be "proper for specialists publicly to advertise themselves as such, or to assume a title not specially granted by a regularly chartered college." If there be the least room for uncertainty, let it be specified distinctly that the adoption of a sectarian title is not merely a violation of medical ethics, but a voluntary disconnection from the regular medical profession, and that professional fellowship is thereby not only inconsistent with self-respect, but prejudicial to the usefulness, the honor, and the true interest of the profession.

I believe that I do not err in saying that those objections made to the Code of Ethics which call for serious consideration betoken either an inadequate appreciation or an erroneous construction of the Code, and, therefore, such objections can be removed by authorized interpretations, which, being simply explanatory, without involving essential changes in the Code, are not subject to the provisions for amendments of articles embraced in the constitution and by-laws of the Association.

I must pass cursorily over the remaining objects for which, as enumerated in the preamble to the plan of organization, our Association was instituted. The means for "enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those engaged in it," furnish many topics which, if time permitted, would claim consideration.

Every member of our profession is often made painfully aware, not only of apathy, but misapprehension, in the public mind, as regards our "duties, responsibilities, and requirements." The popular diffusion of our Code of Ethics, allowing it to speak for itself, would go far toward the removal of many errors in regard to our profession. A valuable service, not less to the public than to the profession, might be rendered by proper efforts in this direction. In this way the public may, perhaps, be led to understand and appreciate the rules of etiquette for which we are often held up to ridicule, our opposition to secret nostrums and patented discoveries or improvements, and our refusal of fellowship with irregular practitioners. Recurring to the last-named topic, many suppose that fellowship with those who are not of the regular profession is refused either from a false sense of dignity or from prejudice, regardless of the dictates of humanity.

Now, the Ethical Code, neither in letter nor spirit, inculcates nothing in conflict with the humane exercise of our calling. This is a superfluous assertion to those familiar with the teachings of the Code. The principles of humanity underlie all its practical precepts. Quoting words which have been already quoted, "The good of the patient is the sole object in view." There are circumstances under which the higher law of philanthropy, placing in abeyance those rules of the ethical code as well as of etiquette which, under other circumstances, claim obedience, not only permits but commands members of the regular profession to bestow their professional services without stopping to ask whether a practitioner with whom chance has brought them into association be, or be not, a "fit associate in consultation." Under such circumstances, association with an irregular practitioner, governed by a supreme regard for humanity, involves neither fellowship nor professional affiliation, and it is to these alone that ethical restrictions apply. Let it not be conceded for an instant that there can be any antagonism between humanity and medical ethics. Nor is it difficult, in particular instances, to decide practically in what way the dictates of humanity are to be harmonized with ethical rules. Regarded in the light derived from both these sources, the path of duty is sufficiently plain. Any act honestly performed purely for a humane purpose, cannot but be consistent with the principle which underlies our admirable Code of Ethics. But, it is to be added, professional association with those who, in the language of the Code, are not "fit associates in consultations," except in emergencies, when philanthropy, for the time being, abolishes all restrictions, contravenes the humane objects of our profession just so far as the useful applications of legitimate medicine are thereby trammelled or curtailed. If it be inhumane, under certain circumstances, to decline association with irregular practitioners, it would be equally, or more so, under other circumstances, to make those concessions which professional fellowship requires to practitioners who profess hostility to medical science, and to the regular medical profession. The refusal of fellowship and affiliation with irregular practitioners, thus, is sanctioned not only by a sentiment of self-respect, and respect for our profession, but by a proper regard for the dictates of humanity.

The work in the several sections of our Association is of importance, aside from its intrinsic value, as a means for "exciting and encouraging emulation and concert of action in the profession." Now that whatever is here done is speedily laid before the profession through the medium of the weekly journal, it is to be hoped that there will be a larger attendance and greater activity at the meetings of the sections than hitherto. It is here that efforts are to be made for the advancement and diffusion of medical knowledge. On the results thereof must be based the estimation, in our own country, of the usefulness of the Association, and its rank as compared with sister associations in other countries. In short, we shall contribute to the true success of the Association, as we increase by our attendance and coöperation the value of the sectional work.

Our Association, both by precept and example, has aimed to facilitate and foster friendly intercourse between those engaged in the practice of medicine. The opportunities for the renewal of old, and the formation of new, friendships, and for social enjoyment, are, in themselves, sufficient to render the meetings of the Association of great value. Let us continue to cherish this last one of the several objects for which our Association was instituted, so that, in this point of view, to the enjoyment of its meetings may be added the pleasures of anticipation and of retrospection.

Our efforts to facilitate and foster friendly intercourse between members of the medical profession, as well as to promote the development and diffusion of medical knowledge, should not be limited to our own country. As the means of union for these objects of the medical profession of all countries, the meetings of the International Medical Congress claim a warm interest. The meeting of the Congress in London, in 1881, will ever be memorable in the retrospections of its members; and they who expect to attend the meeting at Copenhagen in August next, may anticipate much enjoyment as well as improvement. It would prove, as I doubt not, a source of great gratification to the profession of our country if the meeting of the Congress in 1887 were to be held in the United States; and I suggest the propriety of action to be taken now with reference to this desirable end. Inasmuch as an invitation should be in behalf of the profession of the whole country, and not of any particular section, it appropriately should come from the American Medical Association. If the suggestion be favorably received, it seems to me advisable that a committee be appointed with instructions to convey an invitation from this Association through its delegates to the Congress at Copenhagen. The committee may also be empowered to designate the time and place of the meeting of the Congress in 1887, and to take such other preliminary steps as may appear to the committee to be requisite.

My suggestion in regard to the International Medical Congress is not made solely on my own responsibility, but at the instance of several well known for their active interest in the welfare of the American medical profession. By one of the most eminent of these, quite recently, I was requested to make the suggestion in a letter written with a hand tremulous from serious illness which has deprived the Association of his presence at this meeting; one whose absence is a disappointment to many who were desirous to behold once more the genial, benignant countenance which has greeted us heretofore at our annual meetings; one whose writings have made American surgery illustrious; who is revered by the many thousands of practitioners who, during the last half-century, have listened to his instructions, and who is honored not only in our own country, but in other countries, as no member of the medical profession in America was ever honored before; one admired by all who have known him, and beloved by those who have enjoyed the privilege of his friendship. I know that I speak the heartfelt sentiments of every one who hears me and our brethren throughout the whole country when I express a fervent wish that Prof. Samuel D. Gross might be restored to health, and his life spared yet many years to his family, his friends, and his profession, which he adorns.

Brethren of the American Medical Association: I congratulate you on your presence at this annual meeting. It is peculiarly gratifying to meet together in this city, the Capitol of our government, in which there is so much of interest to us as American citizens. There is also much that is attractive in a professional view. We have the opportunity of forming and renewing acquaintance with the eminent members of our profession residing in this city and its vicinity. Here is the Army Medical Museum, the largest and most complete collection in existence of the results of gunshot injuries and of the diseases of armies. It is rich in illustrations of craniology and comparative osteology; and its specimens cover the whole field of medicine and surgery. Here is also the National Medical Library, the largest exclusively medical library in the world, and, as a practical working library, the most valuable owing to its immense collection of periodical literature, and the manner in which it has been indexed and catalogued. All praise and honor to the medical officers connected with the office of the Surgeon-General, to whom our profession and the country are indebted for the labor and skill that have made our National Medical Library and the Army Museum institutions of which we may justly be proud. Let us hope that Congress will not much longer delay in providing a commodious fire-proof building for the reception of the valuable collections which it would be impossible to replace, and which are of the greatest importance to the progress of medical science and education in this country.

The Naval Museum of Hygiene, although of recent growth, will be found to possess an interesting collection illustrating sanitary science, together with a good library. The National Museum, and the Museum of the Department of Agriculture, contain also much that is of interest to members of our profession.

To my congratulations are to be added my thanks for the great honor conferred on me by my election to the presidency of the Association. My grateful appreciation of the honor is enhanced by the fact that I did not seek nor desire the office. I should have been glad had the selection fallen on one better prepared to perform the duties of a presiding officer. I can only say that, relying on your indulgence and forbearance, I shall discharge these duties to the best of my ability.

May this thirty-fifth annual meeting of the Association be characterized by harmony and good feeling. With the blessings of Providence, may its proceedings strengthen the attachment of the American Medical Profession to the Association, extend the boundaries of our knowledge, and promote the welfare of mankind.

THE ADDRESS IN OBSTETRICS.

Delivered May 7, 1884.

BY THADDEUS A. REAMY, M.D.,

PROFESSOR OF OBSTETRICS AND CLINICAL GYNECOLOGY IN THE MEDICAL COLLEGE OF OHIO; GYNECOLOGIST IN THE GOOD SAMARITAN HOSPITAL.

FELLOW-MEMBERS: Custom, as well as law, prescribes as one of the duties of the Chairman of a Section that he present in his annual address a digest of the progress made in that special department during the past year.

Compliance with the letter of this law is now unnecessary, and would, therefore, prove unprofitable. Medical journals, general and special, both home and foreign, conducted with great ability, and exhibiting much energy and zeal in collecting and publishing the latest advances in all departments, are promptly placed by rapid mail facilities upon the table of every reading member of the profession. Moreover, the editorial criticisms of new doctrines, discoveries, methods, or operations are generally from the pens of those who by education and special training have superior abilities for such work. It is, therefore, deemed appropriate, on

the present occasion, to refer you for an "Annual Report on Obstetrics and Diseases of Women" to these more fertile and instructive sources.

Craving your indulgence, I beg leave to offer, in lieu of such an address,

NOTES OF TWO HUNDRED AND THIRTY-ONE CASES OF OPERATION FOR LACERATION OF THE CERVIX UTERI.

The date of my first operation for lacerated cervix, "Emmet's Operation," was February 28, 1874. I have now made the operation upon two hundred and thirty-one patients. Not a single death has occurred. In six cases the operation was followed by perimetritis, parametritis, or peritonitis. In but three of these cases, however, were the symptoms sufficiently severe to cause material delay in complete recovery. In one case, included in these three, there were perimetritis, parametritis, and general peritonitis. The patient was confined to her bed for three months. During the attack (acute stage) the peritoneal cavity was aspirated twice. On one occasion, seventeen ounces of serum were removed. This woman finally recovered her health completely. Considerable immobility of the uterus remained for a long time; but now, at the expiration of two years and a half, its mobility is about normal, and menstruation normal and painless; whereas, prior to the operation, she suffered both from menorrhagia and dysmenorrhœa. She was the mother of two children, the youngest being four years old at the date of operation. No abortions had occurred. Sterility continues.

The above case was one of bilateral laceration, extending on each side to the vaginal junction, the torn lips being widely separated and eroded. I attribute the inflammatory complications following the operation in this case to the undue degree to which the uterus was dragged down in order to give unobstructed access. On this point I shall have something further to say before the close of this paper. Complete recovery ensued in the other two cases, but convalescence was slow.

Of these 231 cases, in 170 the laceration was bilateral, in 38 unilateral. Of these latter, 23 were on the left side, and 15 on the right. 16 cases were stellate, in 2 of which there were four distinct lacerations. In 5 cases there was laceration of the posterior lip only; in 2, of the anterior lip only. In 80 cases the laceration was extensive, in 15 of which it extended to the cervico-vaginal junction on both sides. In 22 of the bilateral cases, the laceration extended to the cervico-vaginal junction on one side only. In 3 cases the rent extended to the internal os. In one of these, the vaginal wall was likewise extensively lacerated: the peritoneal cavity had probably been opened, followed by protracted cellulitis. This patient remained a helpless invalid during the three years intervening between the accident and the date of my operation. On one side it required twelve sutures to close the cervical and vaginal rent. Perfect success followed the operation, the patient being restored to robust health within six months.

In 167 cases there was perineal laceration to an extent that left deformity, either at the vaginal orifice or more externally. In 15 cases the anal sphincter was damaged. In 7 cases the recto-vaginal septum was opened up. In 26 cases I operated upon the cervix and perineum at the same sitting. In 5 cases of this series, I curetted the uterus with my blunt wire curette at the same sitting; this, of course, being the primary of the three procedures. In none of these five cases did a single untoward symptom arise. The results were perfect.

In 50 cases I operated upon the perineum after recovery from the cervical operation. Each of the above-mentioned cases in which the operation involved the recto-vaginal septum is included in this series of fifty subsequent operations. It is perhaps as well to state here that I never hesitate to curette the uterus in a case demanding it, at the time of operating upon the cervix. Nor do I hesitate to use the curette in a case requiring it immediately preceding a perineorrhaphy, pretty extensive clinical experience having convinced me that neither of these operations adds materially to the danger of curetting. Indeed, I am inclined to the opinion that in certain cases in which the conjoined conditions demanding the two operations exist, the depletion of the cervix in trachelorrhaphy presents an element of safety against inflammatory processes which may follow curetting. Three violent cases of traumatic peritonitis have occurred within my personal experience from the use of the curette, unconnected with other operation.

In not a single case of trachelorrhaphy performed by me did secondary hemorrhage occur. In every case in which hemorrhage was troublesome during the operation it was readily controlled by the stream of hot water which it is my custom to have flow upon the field of the operation during its progress, with but three exceptions, in which it being necessary to denude the torn surfaces deeply, twigs of the circular branch of the uterine artery being cut, compression with torsion forceps was invoked. Contrary to the practice of most operators, I have not, since my fourth operation, employed a tourniquet, ligature, or any similar method to control hemorrhage during the operation. As early as 1875, in my clinical lectures delivered in the amphitheatre of the Good Samaritan Hospital, Cincinnati, and repeated each year since, I emphasized the importance of allowing, in most cases, free bleeding from the denuded surfaces. First, (a), because it softens the tissues so as to allow more perfect coaptation of the tips to be united; and (b), because of this softening, which is immediate, the tissues are easily penetrated by the needle in carrying the sutures. Second, most important of all, this depletion not only promotes the return of the indurated cervical tissue to its normal condition, but is an immense factor in again starting the process of involution of the uterus, which had been arrested by the laceration and its consequences.

The restoration of form in closing the divided lips of a torn cervix, especially where the deformity is great, is important. The removal of such pathological conditions as may threaten the development of cancer, and no one can deny that this is in a certain proportion of instances within the scope of the operation, may be even more important; but the influence of trachelorrhaphy properly done, upon subinvolution, cannot be over-estimated. Thorough denudation, cutting out all cicatricial tissue, and allowing free depletion embrace the essential points in the operation so far as its influence upon involution is concerned.

So powerful is the influence of hot water in controlling hemorrhage from small vessels, when it can be poured directly upon the bleeding surface, that I have fre-

quently found it expedient to withhold this agent for a short time after the denudation is completed before introducing the sutures, in order that sufficient bleeding may occur to accomplish the ends above indicated.

The character of the labor which had resulted in laceration, could not be determined with any degree of certainty, except in comparatively few instances, since information upon this point could be obtained only from the patients themselves. In forty cases, delivery was accomplished by the forceps; in two by craniotomy; in two by turning. Two of the cases in which rupture involved the recto-vaginal septum, were forceps deliveries. It is my belief that early rupture of the membranes, and attempts at forcible dilatation of the cervix by the finger or fingers of the accoucheur or midwife, and the improper use of ergot, are far more fruitful sources of laceration of the cervix than the obstetric forceps.

In the city of Cincinnati seventy per centum of all deliveries are attended by midwives, who, with very few exceptions, are ignorant and unskilful. The sins above enumerated lie closely at their doors. But it cannot be denied that these errors of practice are sometimes perpetrated by well-educated physicians. Unquestionably, many cases of laceration occur unavoidably, no matter whatever care and skill may characterize the accoucheur's services. It should be the duty, therefore, of the gynecologist, in all cases in which patients are referred, or otherwise come into his hands for operation, to protect the physician who may have been present at the confinement against censure which may be unjust. All the more because the laity, when informed that a laceration of either cervix or perineum has occurred, at once assume a want of skill or care in the obstetric service. The emphatic declaration of the unavoidableness of these accidents should, by the gynecologist, be voluntary. So great is the danger that professional reputation may unjustly suffer from this source of censure that in an editorial in a recent issue of one of the ablest medical journals in the country, this was used as an argument against the adoption of Emmet's operation, except in extreme cases.

Mr. Jonathan Hutchinson points out that in many cases the first stage of cancer is that of inflammation; that "all inflammations are infective, and inflammatory processes may pass by almost imperceptible gradation into malignancy." The acceptance and appreciation of the above facts would lead, in many cases, to the more vigorous treatment of localized inflammations, more especially when they are situated in structures known from clinical experience to be specially prone to cancer, as the uterine cervix, the mammæ, etc. These considerations alone, even if they were not supported by others, urge upon our attention, with great force, the importance of Emmet's operation. It is the concurrent testimony of almost every distinguished American gynecologist who has expressed himself on this subject, together with many abroad, including Briesky and Schroeder, that the fretting of exposed tissue consequent upon ununited laceration of the cervix is a prolific source of danger in developing cancer.

Emmet, Thomas, Goodell, Mundé, and others, have cited cases verifying this danger. In my own practice quite a number of cases of cancer of the cervix have been observed in which the neoplasm developed either in the cicatricial tissue resulting from the laceration, or in the apex of the cleft. In my opinion, the influence of the accident under discussion in producing cancer has never been fully comprehended by any one. Emmet, the distinguished author of the operation under consideration, at first spoke out unequivocally; now, however, he alleges that he does not make trachelorrhaphy once where formerly he did it ten times; and it is easy to read between the lines of what he has recently written that he does not now believe the evils arising from laceration, not operated on, nearly so universal as he formerly believed them to be. He seems greatly to deplore the extent to which the operation is being done, and, as I think, without just cause. In further considering the relations between this injury and Emmet's operation to cancer, it may not be amiss to call attention to the fact, so thoroughly recognized by clinicians, that cancer of the cervix is almost exclusively found in women who have either given birth to one or more children, or been the subjects of abortion. So far as the cervix is concerned, cancer is a disease of child-bearing women, not of virgins.

In more than three hundred cases of cancer of the cervix of which I have notes, but one occurred in a virgin, and but ten in married women, in whose cases I could obtain no evidence of abortion or child-bearing. Can any one deny that such facts point strongly to the local origin of cancer in these cases at least? And can it be doubted that injuries inflicted upon the cervix during parturition have a direct or remote connection with this origin? Would it not be wise to repair these injuries when they are appreciable by whatever method it may be done most speedily and certainly? It is claimed that Emmet's operation should be limited to cases in which ectropion has occurred or in which a cicatricial plug imprisons or presses upon branches of sentient nerves causing painful reflex symptoms. I have heard it repeatedly stated that, no matter how extensive the laceration, the operation is not warranted unless these symptoms are present. These are, in my judgment, errors. Any laceration which has healed without its surfaces being in contact must have healed without complete union, although its extent may have been much lessened by granulation. But in all such cases there is more or less cicatricial tissue in the field of repair. This does not apply to the many cases in which anterior and posterior laceration occurs, and the parts not being separated complete union has occurred without the aid of the surgeon.

Cicatricial tissue in such locality, even should it not produce reflex symptoms, should be removed thoroughly and the parts closed so as to obtain union by first intention, in which cicatricial tissue is never found. If the rent be small then the operation is small, especially if it be done before chronic inflammation of the cervix has occurred as a result. The denudation need not be extensive or deep. In many cases an anæsthetic need not be administered, as the parts are not very sensitive. The uterus need not be drawn down, so there can be but little danger of cellulitis or peritonitis resulting. Why not do the operation in these slighter cases then as the simplest and safest method of cure, and thus avoid results which might arise in the future and prove more serious?

It is impossible for me to give exact data as to the influence of the operation on sterility, as many of these

cases soon after recovery passed out of my knowledge. And as the last fifty cases were operated on within the past thirteen months, sufficient time has not elapsed to test the question. I know, however, of fifteen cases in which conception has occurred and delivery took place at term. I have no doubt that as many more have proven fruitful. Of these I attended in labor six, one of these within the past month. In no case did relaceration occur, labor being normal except in two cases. In these dilatation of the cervix was slow, but finally complete; in neither case was it protracted. I have learned from medical gentlemen, who attended several of my other cases, that labor was normal. I believe that the operation properly done favors fertility—and often cures sterility. In but two of my cases did union fail. In one of these I foolishly used catgut ligature. In the other failure it was due to the sutures not being sufficiently tightened. In each case subsequent operation was successful.

I may have made the operation in cases not demanding it, but, from my point of view, I do not think so. In eight or ten cases reflex nervous symptoms which I hoped to banish by the operation remained, but in most cases the good effects were obvious; in some cases the cures were almost marvellous. My method of operating, after much thought and some experience, I think worthy of consideration, as it must, as I believe, have some advantages over methods generally adopted.

1. I use nothing but the single volsella to draw the uterus down, with which I seize but one lip, the one to be denuded first, at a time.

2. I draw the uterus down as little as possible. This caution should be the more scrupulously observed if any cellulitis remains about the base of the broad ligaments or elsewhere.

3. I outline the denudation with a sharp knife, and then cut the tissue included in the line with a sharp scissors. This prevents the rolling of tissue at the borders.

4. Allow free bleeding or not, as the condition of the tissue of the cervix and the involution or subinvolution of the uterus may require.

5. Use a nearly half-circle needle with very sharp point, armed with Chinese silk. A needle thus shaped can be drawn through the second lip and withdrawn very much more easily than a straight needle, or one curved only near the point, This advantage is all the more apparent when the uterus is not drawn down, as then the vaginal wall makes the withdrawal of the usual shaped needle difficult. I employ a plain needle-holder without any catch or slide, but strong. Silk is preferred to wire, because it can be tied much more quickly, and the tension more easily adjusted. Then there are no ends to jag the vaginal walls. Another great advantage of the silk over the wire, is in the fact that the sutures may be left in from fifteen to thirty days without danger of cutting out; quite an important matter in a case in which trachelorrhaphy and perineorrhaphy are done at the same sitting. The perineum may heal perfectly and be strong before removing cervical sutures. My custom is to allow the ends of the sutures to remain sufficiently long to reach nearly to the vaginal opening. This facilitates their removal.

6. Wash out the cervical canal at the close of the operation with a recurrent flow syringe, to remove any blood that may have found its way there during closure of the sutures. Have the nurse wash out the vagina with warm carbolized water within an hour after the operation is completed. The vagina is not syringed again until the sixth day; then daily until patient is dismissed. Cleanliness is the only antisepsis employed.

Authorities have been but little quoted, as it is the purpose of this paper to give simply notes of my own cases

ORIGINAL ARTICLES.

DOUBLE OVARIOTOMY; RECOVERY.

By GEORGE F. FRENCH, A.M., M.D.,
PROFESSOR OF OBSTETRICS, MINNESOTA COLLEGE HOSPITAL, MINNEAPOLIS.

Cases of successful single ovariotomy are now so frequently reported that they scarcely arouse professional attention. The following case, however, presents, I think, sufficient complications to insure interest.

Mrs. Z., æt. 31, mother of one child seven years old, came to my office for the first time on May 9, 1883, complaining of an abdominal enlargement, supposed by physicians in the town where she resided to be a uterine fibroid. The tumor was first noticed seven months before, and had gradually attained its present size—that of an ordinary seven months' pregnancy. Mrs. Z. thought she had felt motion repeatedly until within a short time. The growth had caused but little inconvenience until lately, when there had been constant pain in the right side of the abdomen. Flesh and strength had gradually failed, and the patient was seriously reduced. Digestive disturbances had been present from the first; menses irregular and for some months absent; breasts unchanged. On examination, the abdomen was found uniformly enlarged; percussion sound flat in front and tympanitic at the sides; fluctuation indistinct. Through the abdominal walls a firm, hard mass could be felt, reaching from the pubes to the umbilicus, presenting a smooth surface towards the left, and several small prominences on the right. The pelvis was occupied by a tumor continuous with that on the left. No contractions felt; no auscultatory sounds. Ballottement could be felt from Douglas's cul-de-sac. To add to the obscurity of the case, the cervix was large, soft, and blue, and the os patulous.

This condition, as was afterwards discovered, was due to the use of a tent a few days previous to the examination. Notwithstanding the absence of some important signs, the patient was thought to be pregnant at about the seventh month, with possibly a dead child. The patient was advised to remain in town a few days, when a second examination might possibly clear up all doubts; this she could not do. An interval of a month, however, sufficed to clear up the diagnosis and decide the ovarian origin of the enlargement.

June 22.—I was summoned to see the case again with Dr. Milligan, of Wabasha, who had, a few days before, tapped the tumor and drawn off several quarts of thick fluid. The abdominal walls were now lax, the fluid small in quantity, so that the

several cysts of which the tumor was composed could be distinctly felt. The cervix, too, was now small and firm. The uterus could be made out bimanually and separated from the tumor. Its cavity measured three and a half inches. The diagnosis of ovarian cyst being thus demonstrated, it was decided to remove it at once. This was done with the assistance of Dr. Hunter, of Minneapolis, and Drs. Stone, Milligan, and Van Dyke, of Wabasha. The preparation of instrument, sponges, etc., as insisted upon by Lister, was closely followed; no spray, however, was used.

The operation began with the usual incision in the median line, three or four inches in length, beginning just below the umbilicus. Before the peritoneum was reached in the fascia transversalis, two large veins were discovered running directly across the line of incision. These were ligated with catgut. Hemorrhage having ceased, the peritoneum was opened on the director, when a large quantity of ascitic fluid escaped. The cyst was found adherent across its upper surface to the abdominal wall. These adhesions were fresh and easily broken up with the hand, with very little bleeding; no adhesions to the viscera were discovered.

The large cyst presenting at the incision was next punctured with the trocar, and its grumous contents allowed to flow off. The tumor-mass was still very large, but after gentle manipulation and the breaking up of numerous smaller cysts, the walls of which were very fragile, the whole mass, weighing thirty-five pounds, rolled out of the abdomen, attached only by a long pedicle to the right ovary. The abdominal walls were made to hug the tumor, so there was no escape of the bowels, which were protected by broad, flat sponges wet with warm carbolized water.

The pedicle was now examined, and, being found broad and vascular, was transfixed twice by a strong needle armed with silk cord, and tied in three separate parts. The tumor was cut away; the pedicle being absolutely dry, was dropped back into the pelvic cavity. Upon examination the left ovary was found to be a mass of small cysts, equally demanding removal. This was done by piercing the broad ligament as far from the ovary as possible, with a needle carrying a double ligature tied both ways, the ovary cut away and the pedicle dropped back as before. The abdominal and pelvic cavities were now thoroughly sponged out, and the bowels carefully cleansed. The peritoneum covering them was bright red, and the minutest vessels very prominent, with here and there points of exudate—unmistakably incipient peritonitis. The external incision was quickly closed with silver sutures put in place with the Peaslee needle, and the wound covered with carbolized gauze and cotton, held in place by a broad flannel bandage.

The time occupied in removing both ovaries was one hour and ten minutes. The patient rallied well from the operation, but in the second week exhibited a rise of temperature and rapid pulse caused by a small abscess in the abdominal incision. With this exception she made a good recovery, was able to go out of the house in four weeks, and has been well ever since, but has never menstruated.

The deceptive manner in which the several cysts simulated the fœtal parts, the ballottement of one of the cysts, the soft and livid cervix, conspiring to mislead in diagnosis, the double operation and rapid subsidence of the well-marked peritonitis, made the case one of unusual interest.

MEDICAL PROGRESS.

Sublimate Inhalations in Putrid Bronchitis.—Prof. Korányi reports a case of right pleurisy and mitral insufficiency in which putrid bronchitis was subsequently developed. Inhalations of carbolic acid and turpentine were used for four weeks, but caused no change in the character of the sputa. Korányi then used a solution of corrosive sublimate (gr. ½ to water f℥iij), of which ℥v were inhaled every morning and evening. In a week the patient was free of fever, coughed less, and the sputum was much better, and after a few days it was odorless.—*Centralbl. f. d. gesammt. Therap.*, February, 1884.

The Ninth Divulsion of the Stomach.—On March 15th, Prof. Loreta performed this operation upon a young woman, æt. 20, who had stenosis of the cardiac orifice. She was doing well on April 9th. The cause of the stenosis is not stated.—*Gazz. degli Ospitali*, April 9, 1884.

Absence of Kidneys and Uterus.—Dr. Edmondo Coen, assistant pathologist in the University of Bologna, furnishes, in the *Annali Universali di Medicina*, for January, a minute anatomical description, illustrated by figures, of a fœtus without kidneys or uterus.—*Med. Times and Gaz.*, April 12, 1884.

Cold Douches in Febrile Diseases.—Dr. A. Mogiljanski, after giving the history of eighty cases, draws the following conclusions:

1. The cold douche, at 68° to 77° Fah., lowers the temperature in fever not less than a bath at 77° Fah., lasting ten minutes, and if two douches are given at an interval of one hour, the temperature will be more reduced than by the bath.

2. Two douches and one bath produce a more powerful effect than two baths and one douche.

3. The heart's action is slowed by the action of the cold douches, while at the same time the respiration is slowed in a less degree.

4. The muscular strength increases after the use of the douche.

5. Under the douche the respiratory movements become slower, deeper, and irregular.

6. The so-called typhoid state disappears after the use of the douche, though only for a short time. As the inspirations become stronger the lungs are ventilated, and the appearances of hypostasis disappear.—*Centralbl. f. d. gesammt. Therap.*, March, 1884.

Nephrectomy.—Dr. Thomas Savage reports a case of nephrectomy performed in 1883. The right kidney was very large and full of pus. A clamp was used to the meso-nephron. The patient died, but Dr. Savage thinks that the result would have been different had drainage been used here.—*British Medical Journal*, March 8, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE. . . . . $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 10, 1884.

THE AMERICAN MEDICAL ASSOCIATION.

WASHINGTON, May 8, 1884.—The Thirty-first Annual Meeting of the American Medical Association was one of the largest, as well as one of the most successful in the annals of the Association. The attractions of the National Capital with its many beautiful public buildings, and its numerous scientific museums and collections, served to swell the number in attendance to thirteen hundred or more, and the high professional standing of the President of the Association has added to the character and dignity of the proceedings. The programme was full, and the attendance upon the various Sections unusually large. The President's Address was well received, and elicited favorable comment; and in accordance with his recommendation it was unanimously determined by the Association to tender a formal invitation, on behalf of the Medical Profession of the United States, to the International Medical Congress at Copenhagen to hold its next session, in 1887, in the City of Washington.

In the selection of President for the new year the Nominating Committee honored a representative from the South, who is well known, not only for his contributions to our literature, but also by the active interest which for many years he has manifested in the affairs of the Association.

The chief point of interest in the meeting centred in the first annual report of the Trustees of the *Journal*. The exhibit, while not very flattering, was thought to fully justify the Association in continuing, for another year, the publication under the existing arrangements.

At the close of the first day's session, gloom was cast over the Association by the announcement of the death of its venerable and beloved ex-President, Dr. Samuel D. Gross, and as the sad event was announced each Section took action towards honoring his memory, and the Association subsequently, in general session, paid a feeling tribute to the distinguished surgeon, who, ripe in years and full of honors, had just passed away.

The social features of the meeting were not neglected, and receptions at the Executive Mansion by the President, and at private houses were largely attended. Harmony and good feeling universally prevailed, and the Washington meeting will be long remembered as one of the best in the history of the Association.

THE DEATH OF DR. S. D. GROSS.

THIS country has had many eminent surgeons, but among these only two who, each in his day, have stood forth conspicuously above their fellows as the great representatives of American surgery. One of these, Philip Syng Physick, has been numbered with the dead for half a century, and the other, Samuel D. Gross, has just passed away.

There will be sorrow in our land among the profession from the Atlantic to the Pacific, from Maine to Texas, as the tidings reaches them of the death of the great American surgeon. Nay, more, wherever the science of medicine is known, his fame has gone, so that his death will be deplored not only in obscure hamlets and in distant isles, but in the crowded capitals of the world.

A grand life has ended; a great worker, working on until near four score years, has ceased from his labors; the cunning hand that for the saving of life guided the swift scalpel amid living tissues is motionless; the lips which for nearly half a century have been opened to give wise instruction are mute; the noble form which seemed to typify the greatness of the indwelling soul is forever prostrate; and the brain which was so richly stored with all professional knowledge is forever powerless.

Dr. Gross's life-work is done; and how great that work has been! In Cincinnati, in Louisville, in New York, and in Philadelphia he has been a medical teacher, and the thousands he has taught are scattered over the length and the breadth of the land. He has been recognized as the greatest teacher of the principles of surgery our country has ever had. His lectures, always carefully prepared,

and delivered without manuscript, save brief heads of the different parts of the discourse, were models of simplicity, and clearness of language, and completeness, and were delivered in a most impressive manner; he taught with authority, and, therefore, with power.

Dr. Gross, almost from the beginning of his work as a medical teacher lecturing to large classes, and lecturing for so many years, has been the teacher of more physicians than any one upon the continent. When we add to this the influence exerted by his writings, especially by his surgery, Dr. Gross has wielded a great and extensive power—greater and more extensive than that of any predecessor, in this country, at least.

As a practitioner, he was kind and devoted to his patients, shrinking from no exposure, and from no sacrifice of time and rest in their behalf. Other operators may have excelled him in mechanical skill, but none in wise judgment, and in hearty devotion to the interests of his patients.

He was in every element of his being and life a doctor, thoroughly devoted to his profession, constantly striving to advance its interests, and to promote the welfare of its individual members. How many a doctor, whether private pupil, or simply an attendant upon his lectures, or even without any previous acquaintance, has had from him kind words, wise advice, a helping hand. He has done much, by his words and by his example, to implant hope, stimulate ambition, to incite men to work, and thus rise to usefulness and honor, as the just reward of honest labor. To-day the American medical profession occupies a higher position because of the living influence and work of Dr. Gross.

Among his colleagues in the profession he was regarded with the greatest love and esteem. In the American Medical Association he was an irresistible power. When he rose to speak, what a hush of eager expectation; how every eye was turned to look upon that noble presence, the grand brow with its seal of intellectual power, the silver hair that seemed to tell of wisdom, the calm, kind face lighted with a genial smile expressive of a benevolent heart. Children playing with one who afterward became a famous monarch and conqueror in ancient times, as if with prophetic inspiration, crowned him king; but who, having seen Dr. Gross in the American Medical Association, or in other medical bodies, has not felt that he was a king amongst men, noble as the best of earth-born monarchs.

Few men have contributed as much as he has to medical literature. His writings extended over the field of obstetrics and pathology, as well as surgery, and the great work of his life, his *System of Surgery*, will stand an enduring monument of his surgical judgment and lore. When we join to the books he wrote, his contributions to periodical literature, to medical societies, and his public addresses, the amount of his literary professional work appears immense. His advancing years did not hinder him from placing on record the valuable experience of his long professional life, for within a few weeks of his death he prepared two very able papers, one for the American Surgical Association, and the other for the Obstetric Section of the American Medical Association, which he purposed reading before the respective bodies, but, alas, the hand of fate has ruled otherwise.

Dr. Gross was one of the most genial of companions, one of the most generous of hosts; his large knowledge of men and affairs, his extensive study of books, especially of those belonging to the profession, made his conversation both interesting and instructive, while his hospitality was proverbial.

He was the recipient of many and great honors. He was the founder of the Pathological Society of Philadelphia, of the Philadelphia Academy of Surgery, and of the American Surgical Society, and president of each of these bodies. He has been president of the State Medical Society, and of the American Medical Association, and of the International Medical Congress which met in Philadelphia in 1876. From the three great seats of learning in Great Britain he has received its highest honors — LL.D. from Oxford in 1878, from Cambridge D.C.L. in 1880, and LL.D. from Edinburgh in 1884, and from the University of Pennsylvania last week the title of LL.D. He was a member of various learned societies both in this country and in Europe.

Probably the most pleasing tribute paid to the worth and work of this noble man was the complimentary dinner given him by the profession of this city just five years ago. No one who was present can forget that memorable occasion; how heartily all bore willing tribute of admiration and love to the guest of the evening. The following passage in Dr. Gross's address was eminently characteristic of the man, of his work, and of his faith: "Oh! for a glance at the profession half a century hence, when man, enlightened and refined by education, and redeemed from the thraldom of ignorance and superstition, shall reflect more perfectly than he now does the image of his Maker." That was the spirit in which Lord Bacon believed medicine should be exercised, "For the glory of God, and for the good of man's estate."

Dr. Gross's great success is to be attributed to his constant work, to his indefatigable industry. Quite as much as any man in the profession he illustrated the truth of Velpeau's dying words: *Il faut toujours travailler, mes amis.*

Chance is one of the smallest elements, if element at all, in honorable professional success.

"The heights by great men reached and kept,
Were not obtained by sudden flight,
But they, while their companions slept,
Were toiling upward to the light."

There is thus no mystery in the grand success of Dr. Gross's life. He labored faithfully and systematically, and had the just reward of his toil; in all positions and in all duties he was true to the profession, and the profession was true to him, honoring, admiring, loving him in life, and in death revering his memory.

On a subsequent page will be found a complete biographical sketch of Dr. Gross.

THE SANITARY SUPERVISION OF TRANSATLANTIC STEAMERS.

The extremely unsatisfactory condition of the medical service on transatlantic steamers, upon which we commented last week, is an evil which demands prompt remedy. The danger which constantly threatens the country from the introduction of infectious diseases, against which no suitable sanitary precautions have ever been instituted, either before embarkation, during the voyage, or at the ports of entry on this side of the Atlantic, is a question of very serious national concern, and, therefore, should very properly enlist the attentive consideration and judicious intervention of the General Government.

There is no doubt as to the frequent dissemination of infectious diseases throughout the country from lack of efficient marine medical service, and want of rigid application of necessary sanitary regulations at the ports of departure and entry and on shipboard. Instances have again and again been reported of outbreaks of disease clearly and definitely traced to persons infected previous to embarkation or during transit. So notorious did this fact become in 1882, as regards smallpox, that the National Board of Health was obliged to interfere with such limited authority as it possessed, to the end that the passengers arriving from infected places should be inspected and vaccinated when deemed to be insufficiently protected. This action, however, was not at all satisfactory, and had to be supplemented by an inspection service of immigrants, instituted at different points in the west. In the spring of the same year smallpox, scarlet fever, and measles were introduced in one of our ports through inefficiency of the medical and sanitary regulation of the transatlantic steamer service.

The effects of this common neglect of precautionary measures are palpable and far-reaching. The remedy, if left to the option of the ship-owners, will not be applied, as experience has proved. The authoritative intervention of the Government is required to guard the country from the development and spread of disease introduced from abroad. This may be accomplished, as has been suggested, by requiring all persons coming to the United States to show evidence of having been properly vaccinated at least fourteen days previous to embarkation; by insisting that vessels carrying passengers shall provide suitable hospital accommodation, and necessary assistance for the care of the sick; and by establishing a competent service of marine medical officers, who, being entirely independent of interested influences, will see the law observed throughout the voyage, and will be responsible to the Government for the faithful discharge of their duties and their intelligent coöperation with the quarantine authorities.

NEW TEST FOR PEPTONES.

Since some of the most delicate tests for albumen are rendered of doubtful value because they also produce reactions with peptones, the recent announcement to the Academy of Natural Sciences of Philadelphia, by Dr. N. Archer Randolph, of a new test for peptones is of great importance. It is based upon the fact that if the acid nitrate of mercury, Millon's reagent, be added to a cold aqueous solution of potassic iodide, a red precipitate of mercuric iodide always appears. If, however, either the peptones or biliary salts be present, the precipitate of nascent mercuric iodide assumes a yellow color.

In order to render the test sensitive to minute quantities of the substances in question, it is necessary to limit the quantity of potassic iodide employed. To each five cubic centimetres of the suspected fluid, which must be cold, and either neutral or faintly acid, two drops of a saturated solution of the reagent should be added, thoroughly mixing the whole. Now if four or five drops of Millon's reagent be added, and peptones or biliary salts be present, the yellow color appears. The question as to the presence of biliary salts is easily eliminated.

By this test, Dr. Randolph has been able to detect peptones in the proportion of 1 to 17,000 parts of water.

THE ACTION OF SALICYLATE OF SODIUM UPON THE UTERUS.

The conclusions of Dr. Balette (*Thèse de Paris*) are that salicylate of sodium, in the ordinary therapeutic dose, calms the pains of dysmenorrhœa, apppears to promote menstruation, and causes its reappearance in amenorrhœa. In four cases of pregnant women, in which the medicine was given in large doses, abortion occurred in two; but no such result was observed in other cases of pregnancy in which the remedy was administered in moderate quantity.

SOCIETY PROCEEDINGS.

THE AMERICAN MEDICAL ASSOCIATION.

Thirty-fifth Annual Meeting, held at Washington, May 6, 7, 8, and 9, 1884.

(By Telegraph.)

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, MAY 6TH—FIRST DAY.

GENERAL SESSION.

THE Association was called to order by A. Y. P. GARNETT, M.D., of Washington, Chairman of the Committee of Arrangements, who, after prayer, introduced, in the absence of the ex-President, Dr. Atlee, the PRESIDENT, DR. AUSTIN FLINT, of New York, and then delivered an *Address of Welcome.*

THE COMMITTEE OF ARRANGEMENTS

then presented a report. The list of receptions tendered the Association was announced. It included receptions by the President of the United States, the Medical Profession of Washington, Mr. W. W. Corcoran and the Board of Trustees of the Corcoran Art Gallery, Commissioner and Mrs. Loring, Chief Justice Waite, the Surgeon-General and Staff of U. S. Army, the Hon. George F. Edmunds, President *pro tempore* of the Senate, and Hon. John G. Carlisle, Speaker of the House of Representatives, and by a number of other prominent citizens. An invitation was also given the Association to visit the National Insane Asylum and the Hospital in connection with it.

Letters were reported from A. Pearce Gould, F.R.C.S., and other distinguished medical men of Europe, to whom invitations to attend the meeting of the American Medical Association had been sent.

THE REPORT OF THE COMMITTEE ON REGISTRATION

was read in full, and the election of the delegates who were therein registered confirmed, a motion to suspend the reading of the report not being sustained.

A letter was received from

DR. JOHN L. ATLEE,

ex-President, expressing regret at his inability to be present, which was ordered printed with the *Transactions.*

The ex-presidents of the Association were invited to seats on the platform.

THE PRESIDENT, DR. AUSTIN FLINT, then delivered the

ANNUAL ADDRESS.

(See p. 523.)

DR. J. M. TONER, of Washington, moved a vote of thanks to the President for his admirable address, and that the address be requested for publication. Unanimously adopted.

He also offered the following resolution concerning

DR. S. D. GROSS,

which was also unanimously adopted by a standing vote.

Whereas, It has come to the knowledge of this Association that one of its former presidents and a surgeon of world-wide reputation is confined to his room by illness, therefore, be it

Resolved, That the American Medical Association expresses to Dr. S. D. Gross its heartfelt sympathy in his illness, and the sincere wish for his speedy recovery and preservation for many years to the enlargement of the world-wide reputation and justly merited honors to which he has attained.

On motion, the above resolution was telegraphed to Dr. Gross.

DR. RICHARDSON, of Georgia, stated that he had just left the bedside of the very ill and honored ex-president of the Association, and that when he asked him for any message that he might desire to send, the reply of Dr. Gross was, in a feeble voice, "Give them my love!"

DR. SAYRE, of New York, made a motion that a committee be appointed to invite the International Medical Congress, which is to meet in Copenhagen, to select the place of its next meeting in this country.

DR. GARCELON, of Maine, moved that the Address be referred to a committee of five, to take action upon the various important questions concerned in it, and report to the Association as soon as possible. This was amended so as to read "a committee of seven," and adopted.

The Association then adjourned.

SECTION MEETINGS.

SECTION ON PRACTICAL MEDICINE.

The Section met in the Congregational Church, Cor. of 10th and G Streets, Washington, at 2.30 P.M., DR. J. V. SHOEMAKER, of Pennsylvania, *Chairman*, in the Chair.

DR. E. G. JANEWAY, of New York, read a paper on

THE DANGER OF RELYING TOO MUCH UPON SO-CALLED PATHOGNOMONIC SIGNS OF DISEASE.

It is often a very brilliant thing, he said, to make a snap diagnosis, but it is not safe to do so; for many so-called pathognomonic signs of special diseases are found, on closer inspection, not to be so in reality. For instance, optic neuritis, conjoined with headache, used to be considered as a pathognomonic sign of cerebral tumor. This is not so. We know that it only means that there is some increased pressure in the brain. You must also eliminate Bright's disease of the kidneys. Volitional tremor is thought by some to be very characteristic of multiple sclerosis, but a similar condition is observed in patients who are under the influence of metallic poisons such as mercury, and also in those who have partaken freely of alcoholic stimulants. We often find considerable difficulty in cases of coma, in endeavoring to decide whether it is of hemorrhagic or uræmic origin. The variations in the temperature of the body are here a valuable help in our investigation; but they are not sufficiently certain to found a positive conclusion upon. The existence of heart murmur, or the absence of it, does not positively settle the point as to whether there is an embolus in the brain or a hemorrhage; and albumen in the urine is often associated with these lesions. The author went on to consider the so-called pathognomonic signs of other diseases—referring to heart and chest disease. It is not wise to rely too much upon these signs, but to take the whole bearing of the case in making the diagnosis.

DR. FRANK DONALDSON, of Baltimore, in opening the discussion, spoke of cardiac murmurs. He had

known of cases in which the autopsy showed marked stenosis of the mitral orifice which had presented no murmur during life.

Dr. Janeway said that in some cases of pleurisy of slight grade bronchial breathing is not present, and he had seen people much misled by it. In regard to mitral stenosis, he thought that it could sometimes be detected by a long first sound with a slightly blubbering character, even when there was no murmur.

Dr. Austin Flint, of New York, then read a paper on

THE CLINICAL STUDY OF HEART SOUNDS.

This field of research is, he said, a comparatively uncultivated one. In 1858 he read a paper on this subject before the American Medical Association in Washington. This paper which he was now reading he designed to be supplementary to the former one. The views he then expressed, as to the value of the study of heart *sounds* as opposed to *murmurs* (or adventitious sounds added on to or replacing the normal sounds), he still holds. Cardiac murmurs are very important, and they are being carefully studied, but the sounds are too much neglected.

He considered the ordinary division of cardiac sounds into two kinds—the first, or systolic; the second, or diastolic, to be very incomplete. He thought the proper classification would be to say there are five sounds—two of which are disastolic and three systolic.

The diastolic are (1) the aortic and (2) the pulmonary, heard in the right and left second intercostal spaces respectively. The systolic are (1) the mitral, (2) the tricuspid, and (3) the sound caused by the propulsion of the heart against the chest walls, which he would call the impulsion.

This last is heard best at the apex, and determines the length and intensity of the first sound of the heart, and gives the booming character that is heard with this sound. The impulsion sound is heard over only a limited area. The best place to hear the mitral sound proper is in the fourth intercostal space, far enough to the left to eliminate the sound caused by the impulsion. Here the sound is of a purely valvular character. The tricuspid sound is heard at the base of the xiphoid cartilage. Its maximum also is found where the effect of the impulsion of the heart can be eliminated.

Changes in the aortic sound. Incompetency of these valves gives rise to a diastolic murmur. But this murmur furnishes evidence of nothing more than the simple fact that there is an incompetency. Of the extent of the incompetency it furnishes no index whatever. This information must be obtained by the strength or weakness of the aortic sound which is heard along with the murmur, as compared with that of the semilunar valves on the right side, provided these be under normal conditions, or, better still, by noting the character of the impulsive sound of the left ventricle. If this be much interfered with, it is a sign of marked overfilling of the left ventricle, and of a considerable degree of insufficiency.

The aortic sound may be diminished also by the lessened quantity of blood sent into it by the left ventricle, as in cases of mitral disease. It may be increased in one of two ways: by the increased force of the systole of the heart, or by increased pressure in the systemic arteries, as, for example, in contracted kidney. This last cause, which is so much dwelt upon by many authorities as to be taken as almost pathognomonic of contracted kidney, Prof. Flint looked upon as being very doubtful. In some experiments undertaken by Dr. C. F. Roy, in which he abruptly cut off a considerable part of the general circulation by tying a main artery leading to the part, there was hardly the slightest effect produced on the aortic sound. As a matter of clinical experience, he knew that this state of the aortic sound did exist without the disease in the kidney, and *vice versâ*.

Changes in the pulmonary sound. This may be increased or diminished. Skoda pointed out the increase in the sound that is noted when the right ventricle is hypertrophied. Besides this the sound is intensified by anything causing obstruction in the circulation of the blood through the lungs. Increased blood pressure is met with in the pulmonary circulation in various diseases of the lungs, such as pneumonia, capillary bronchitis, emphysema, pleurisy, etc., and the amount of increase in the intensity of the pulmonary sound is a gauge of the amount of obstruction in the lung. When the heart is beating more rapidly than usual, as after exertion or in mental excitement, the pulmonary sound is more increased than the aortic from this same reason.

As to the significance of diminished intensity of the pulmonary sound, Dr. Flint would not say much. It would be present in regurgitation, which, however, is an extremely rare affection. The absence of the sound in aortic trouble is also of little practical moment.

Changes in the mitral sound. Heard at the place recommended by him at the beginning of the paper, the mitral sound is short and valvular. A systolic murmur here denotes simply incompetency of the mitral valve, but gives no information as to the degree. The weakness of the sound heard with the murmur will give a clue to this. The sound will also be weak when there is fatty degeneration or dilatation of the heart. In overfilling of the left ventricle, the excursive movements of the mitral valve are interfered with, and are lessened. The tension of the valves during the systole will, under these circumstances, be not sufficient to occasion much sound, for the intensity is in proportion to the excursive movement of the valves. In anæmia the sound is intensified. In cases in which there is a presystolic murmur, and the sound is more intense, it shows that the curtains of the valves adhere to one another, leaving a buttonhole opening. In these cases the action of the valves is strong, and there may be no systolic murmur.

Impulsion sound. This generally predominates very much in healthy persons. It may be increased, decreased, or lost. As it is an ex-cardial sound, and is not transmitted, it is heard over only a limited area. It has a specially booming character in hypertrophy. It is diminished in fatty degeneration and in softening of the tissues of the heart, in fevers—when it serves an important purpose in indicating the need of stimulants, etc. In pericarditis, it is lost during the stage of effusion. In these cases, the aortic sound may be louder at the apex than the mitral.

Tricuspid sound. Weakness of this sound is of slight importance. A thrombus in the right ventricle has been known to extinguish the sound altogether. In hypertrophy of the right ventricle it is intensified, and this is a better sign of this condition than the increased inten-

sity of the pulmonary sounds, since that depends so much on the variations in the blood-pressure in the pulmonary artery. Disease of this valve is rare, except as a congenital trouble.

DR. F. C. SHATTUCK noticed that Dr. Flint ignored the muscular element in the production of the first sound, which is regarded as so important by many. There is a difficulty in the theory that contracting muscles make appreciable sound. In hypertrophy following aortic disease, the first sound is sometimes wanting.

DR. JAMES C. WILSON, of Philadelphia, said that, in Germany, emphasis had been laid upon the study of heart *sounds* as well as of murmurs, and referred to the work of Felix v. Niemeyer. There is some doubt as to the part played in the production of the first sound by the contraction of the muscles.

DR. RICHARD MCSHERRY, of Baltimore, entered into the consideration of the general progress of exactness in our methods of diagnosticating cardiac affections, from the time when the stethoscope was called a "divining rod" by the old physicians, to the present day.

At this period the announcement of the death of PROF. S. D. GROSS, of Philadelphia, was made, and a motion was put to adjourn out of respect to his memory. Prof. A. Flint said that he had been intimately associated with Prof Gross for many years, and felt sure that he would be the last man to wish the proceedings of this convention to be suspended. The motion was lost.

DR. GARLAND, of Massachusetts, spoke of the importance of eliminating the effect on cardiac sounds of the respiratory movements. In cases of any doubt always examine the heart during forced inspiration and forced expiration.

DR. DONALDSON, of Baltimore, thought it doubtful whether impulsion could be considered a *sound*. It adds to the intensity, but is hardly a sound *per se*. He denied the muscular element in the production of any sound capable of being heard by ordinary methods. He then entered at length upon the origin of the presystolic murmur, which he was rather inclined to consider, with Leaming, to be produced at the commencement of the systolic sound, and not by the contraction of the auricle, which was so slight and weak.

DR. JANEWAY, of New York, said that in cases in which there was a presystolic murmur, the auricle was hypertrophied and its contractions were therefore stronger—there was also felt a presystolic thrill.

DR. J. S. LYNCH did not agree with Dr. Flint in regard to the absence of increased aortic sound in cases of contracted kidney. He noticed that Dr. Flint assumed increased tension in the pulmonary artery to be the cause of increased intensity of the pulmonary sound. Why, therefore, did he deny a similar cause in the production of an increased intensity of the aortic sound? He also noticed that Dr. Flint had taken no account of the systolic vibrations of the aorta in the production of the first sound of the heart. It was this, Dr. Lynch thought, that gave the first sound its booming character.

DR. FLINT said that he would not reply to the remarks that had been made as to the cause of cardiac murmurs, nor even to the cause of cardiac sounds, as time was limited and he had confined himself to clinical questions exclusively. In regard to Dr. Lynch's objection to the inconsistency of denying increased pressure in the systemic arteries to be a cause of increase in the intensity of the aortic sound, he had no explanation; he based his conclusions on clinical facts.

DR. LOUIS A. DUHRING, of Phila., then read a paper on

DERMATITIS HERPETIFORMIS.

Under this name Dr. Duhring described a most protean form of skin disease which had hitherto been classed under numerous different names, and had often been left nameless. One form of it had been described by Hebra as impetigo herpetiformis, as a rare and grave disease of which Hebra had had five cases, four of which had died. This, however, was only one form of the disease. In Dr. Duhring's hands the disease, while very intractable, had never ended fatally. He described several varieties, as the pustular, the vesicular, etc. As the disease is so protean in its forms, and certainly herpetic in character, he considered the name he had adopted answered it the best of any. All forms have certain things in common; there are malaise and considerable constitutional disturbance for several days before the appearance of the eruption and intense itching, which continues till the lesions have been ruptured. There is considerable febrile action. The eruption appears mostly over the anterior part of thighs and trunk. It is confined to neither sex, but appears mostly in adult life. It is certainly a systemic disease, and is very intractable and extremely liable to recur.

The next paper was on the

ETIOLOGY OF PERICARDITIS,

by DR. JAMES WHITTAKER, of Ohio. This disease is more often overlooked than suspected, and it is often latent, owing to the fact that frequently the local symptoms are slight, and where there is no history of rheumatism it is apt to be overlooked. Rheumatism is the most frequent single cause, but it does not cause the majority of all the cases. Of the frequency of pericarditis, the author quoted statistics showing that about four per cent. of autopsies give evidence of the existence of pericarditis, which is really higher than the proportion of endocarditis; clinically, endocarditis would seem to be more common. Pericarditis should not be classified as primary and secondary, but as mechanical and infectious—the first arises from injuries and from extension of inflammation from contiguous parts, etc.; the second, which is the true pericarditis, occurs in diseases dependent upon the existence of a microörganism. Rheumatism heads the list, then pyæmia, septicæmia, typhus and typhoid fevers, scarlatina, etc., malignant dysentery, cholera—in short, all diseases that have a mycotic origin. Three cases have been reported as occurring after vaccination. Infantile pericarditis has generally been referred to puerperal disease in the mother having extended to the child. It proves fatal in the first sixteen days of life. Endocarditis is frequently associated with pericarditis. The treatment medicinally should be anti-mycotics, cold, and rest.

DR. PRENTISS'S paper on *The Pharmacopœia* was, on account of the sickness of the author, read by title and referred to the Publication Committee.

DR. G. V. BLACK, of Illinois, read a paper on the

PRODUCTION OF POISONS BY MICROÖRGANISMS.

The association of certain germs with many diseases is pretty certain, but how they cause or modify disease is not explained. The author proceeded to show how

in all living things—plants and animals—there must be digestion, effected by some fluid secreted by the organism which will act as a solvent—there must be absorption of this material and appropriation of it to the needs of the life, and then the throwing off of the waste material. He said that in all forms of life (except the egg and the seed) excretion was of two kinds—one corresponding to the respiratory execution, which was rich in oxygen, and one corresponding to urea, which was poor in oxygen. In the yeast plant there are, *e.g.*, the carbonic acid, which is the respiratory excretion, and the alcohol, which corresponds to the urea. In plants the alkaloids, which are deposited in the unused part of the tree, are the true analogues of urea in man. The higher plants consume the smallest amount of food in proportion to the amount of structure building; they, therefore, excrete little. The case is just the reverse with the lowest forms of vegetable life. This general process he called remolecularization. These excreta are generally poisons to the animal or vegetable excreting them. But the poisonous character of the microörganisms varies as do the alkaloids found in trees and plants. The poison in the microörganisms corresponds to the alkaloids in trees and plants. It is their excreta that renders them dangerous. Before their true effect on the organism can be known, these excreta must be separated and analyzed.

Dr. Traill Green, of Penna., then read a paper on

THE NEW CHLORATE,

in which he praised the chlorate of sodium, thinking it superior to the potassium chlorate in every case in which the latter is useful, as being more soluble and far less irritating to the stomach. It can be given in larger doses, and, therefore, is more efficacious. As a local application in poisoning from the mercury vine, in the proportion of 4 to 12 grammes to 500 cubic centimetres of water, it is most satisfactory; also as a local wash in scarlatina. In conjunctivitis, and in irritations of mucous membranes ending in the skin (piles, etc.), it is most soothing. He thought the sodium salts in every way preferable to the potassium salts, and illustrated the difference in the irritating qualities of sodium and potassium salts, in the use of bicarbonate of sodium in burns, which answers well, while no one would think of using bicarbonate of potassium for the same purpose. In conclusion, he said that if any physician would try the effect of substituting sodium chlorate for potassium chlorate in his practice for one month, he felt sure that they would discard the potassium for the sodium. He had seen a case of angina yield to sodium chlorate that had resisted the potassium salt.

Section on Surgery.

The Surgical Section assembled at 2.30 P.M., with C. T. Parkes, M.D., of Chicago, in the Chair.

On motion of Dr. Keller, of Arkansas, it was decided to limit each speech in the discussion of the several papers to five minutes, speakers to have a second hearing only by consent of the Section.

The only paper read was that of Dr. Frederick S. Dennis, of New York, on the

TREATMENT OF COMPOUND FRACTURES.

In advocating any special kind of treatment, the speaker said, there are several salient points to consider. First, the method should be a safe one, and proved to be such by the crucial test of experience. Second, it should yield results unattended by any septic infection, by shortening, and by deformity. Third, it should be a simple one, unaccompanied by compound splints and cumbersome apparatus.

As essential for the attainment of good results, by whatever method, the author gave these rules: Immediate fixation, absolute cleanliness, and arrangements for thorough drainage when necessary.

Immediately after the injury has been sustained, he said, the wound should be carefully washed with a solution of carbolic acid, or irrigated with a solution of the bichloride of mercury, and the plaster-of-Paris bandage immediately applied. The bone, if it protrudes and cannot be reduced, should be sawn off with the chain-saw. A fenestrum is cut through the bandage to permit free drainage. This was the method employed by the author, and from its use he reported that primary union had occurred in a number of cases, without a sign of suppuration, and without the use of a fenestrum in the bandage. When suppuration does occur, however, the keynote to success is to keep the parts free from septic irritation, which is accomplished by free drainage and frequent cleansing with antiseptic solutions. When the granulating surface is pale and unhealthy in appearance, a poultice sprinkled with red cinchona bark should be applied. When the parts are healthy, iodoform may be used.

The author then defined what is meant by a compound fracture, stating that the entrance of air to the seat of fracture is an essential condition to its definition, and that, hence, the wound through the soft parts is produced by the injured parts within pushing out. The difference in the manner of union of simple and of compound fractures was treated of. In submitting his report to the Section, the author said that he would endeavor to show that the result was at least as good as that obtained from any other plan of treatment. It was unattended in any case with non-union and deformity, and his records, as regards shortening, were as satisfactory as any, and during the process of repair there was as little disturbance of health as was found in any plan of treatment.

The speaker then reported 128 consecutive cases of compound fracture of various parts of the body, with a tabular statement of the results. The report may be summarized thus: Compound fractures of skull, 22 with 6 deaths. Of the 16 recovering, 10 were trephined. Compound fractures of thigh, 3; leg, 48; arm, 10; forearm, 13; lower jaw, 8; hand and foot, 19; ribs and nasal bones, 4; miscellaneous cases, 30. Deducting from these cases those who died from shock or within forty-eight hours after injury, he had 95 cases without a death. This mortality was lower, he showed from statistics, than that reported from treatment by the strictest antiseptic Listerian method.

Just at the close of the reading of this paper, the President was handed a telegram containing the sad intelligence of

THE DEATH OF DR. S. D. GROSS.

On motion, a committee was appointed to draft resolutions upon the death of the esteemed member, and the Section was adjourned until Wednesday afternoon.

SECTION ON OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

DR. J. F. CHISOLM, *Chairman*, called the Section to order, after which the first paper was announced, viz.,

NEOPLASMS OF THE LACHRYMAL GLANDS,

by DR. P. D. KEYSER, of Penna. He stated that he believed this disease to be of very rare occurrence, and, having had two interesting cases lately, he wished to give some of the results of his study of them. He then described the first one, in which the patient (aged fifty-five years) was found to have an almond-shaped lump over the eye-ball, which it pushed down, and pressure on which occasioned some pain. It had existed for several years. Vision 20.20 (old notation). Tumor diagnosticated as enlarged lachrymal gland. On removal it was one inch and a half in length by the same in depth, and twice the normal thickness.

Microscopical examination showed the new growth to spring from the centre of the gland, while the outer portion showed inflammation cells only.

After the lapse of two years, there had been no return. The study of these tumors, microscopically, was of interest as helping to decide the question of their origin; some writers maintaining that they always started in the gland itself, while an external origin, gradually invading the gland, was probable from some cases observed.

The second case was then described; patient aged forty-seven; tumor raising upper lid so that it could not be closed; pupil slightly contracted; vision 20.20; no pain whatever. At a later examination the tumor felt hard and firm; local applications had no effect. It was then removed, and Dr. Seiler made a microscopical examination of it. This showed numerous round-cells and a stroma, but no alveolar cells. A purely fibrous capsule enclosed the growth. This was in May, and by October of same year a second growth had appeared, twice the size of first.

This showed a different structure from the first, and was pronounced a round-cell sarcoma; no capsule found. A *third* growth ultimately formed in the same eye. The speaker said that these growths, when confined to the gland, gave a sure prospect of recovery by removal, but, extending into surrounding tissues, were apt to return.

DR. WILLIAMS spoke of the permanent ptosis which was apt to follow on the removal of these tumors, and had himself sometimes been inclined to attribute it to inadvertent cutting of the levator palpebræ. He thought the disease very rare.

THE CHAIRMAN stated that he had seen four or five of these growths, mostly of a malignant character, and related one case in which, in a young woman of twenty-three, it had existed from childhood, pushing the eye out so slowly that vision had been retained, though impaired. Microscopic examination showed calcareous deposit.

DRS. BURNETT and THOMPSON took part in the discussion, the latter describing a growth of the gland which returned rapidly after removal; the second tumor was hard, and squeaked under the knife. This was pronounced scirrhus by a microscopist in Indiana, but he believed this opinion to be incorrect.

DR. E. WILLIAMS, of Ohio, then read a paper on

DIAGNOSIS IN OPHTHALMOLOGY.

He spoke of the importance of thorough preparation on the part of medical men for the practice of this branch of medicine. He believed that no physician was qualified to practise in a special department without a broad general study as a ground-work. He gave a feeling account of the injury done to the public by ignorant pretenders in the science of ophthalmology, and eulogized the American Medical Association for its action in ruling out all advertising quacks. He believed that the remedy lay in greater care on the part of private physicians in recommending students as proper persons to study medicine. The colleges of the country were also to blame, he thought, as they too frequently "ground out from the screenings" material for the medical profession which might have achieved success in the mechanical arts, but made poor doctors. A more general knowledge of the principles of the science would also deter "general surgeons" from ophthalmic surgery, when not qualified for successful practice in that line.

Dr. Williams then referred at length to the important connections of disease of the eye with other general disorders, instancing retinitic albuminuria, ophthalmia neonatorum, and eye symptoms in disease of the brain and spinal cord.

He then described a case of sudden loss of sight in the right eye by a single lady who had just passed the climacteric period, which, with the hemorrhage detected in the affected eye, he attributed to the cessation of the catamenia, and consequent disturbance of the system. In internal strabismus of long standing he had made a rule to refuse to operate; incurable diplopia was likely to follow.

DR. KEYSER stated that he had operated with success in long-standing strabismus by cutting out a piece of the paralyzed rectus externus, and joining the severed ends.

DR. SAMUEL D. RISLEY, of Pennsylvania, then read a paper on

SYMPATHETIC NEURO-RETINITIS, WITH REMARKS,

in which he related the rise and progress of a typical case. This paper brought out an extended discussion, in which a number of the members joined, and all referred to the importance of sure guides to the ophthalmic surgeon in cases of threatened injury to a sound eye by spread of inflammation, and elicited somewhat divergent views on the subject, according to the individual experience of the speakers.

DR. STEVENSON related a case in which, by "sympathetic" irritation, inflammation was transmitted to the brain and meninges with fatal result.

DR. WILLIAMS spoke in favor of a conservative policy in these cases. He believed that harm had been done by a too sweeping application of the preventive treatment by enucleation; an eye might be saved that would be much better than no eye at all.

DR. WM. S. LITTLE related a case in which a patient stubbornly refused to submit to enucleation of an injured eye, became blind, as his surgeon predicted, and subsequently *recovered* the sight, the inflammation subsiding and leaving a useful eye. He has generally refused to operate in old people for "subjective traumatism" after injury sustained long before.

Dr. Thompson thought that while in addressing ophthalmologists of special training, these views might do no harm, yet he thought that the general public should not be treated with high-colored accounts of recovery after refusing to submit to operation as advised by the eye-surgeon, lest false inferences might gain ground to the detriment of ophthalmic surgery.

Dr. Hobby then related a case that had come under his care, and a portion of the time under Dr. Young's. He operated for relief from pain from the effects of a past iritis. The eye became subsequently violently inflamed, and, as the patient lived far from surgical aid, it was decided not to wait for sympathetic irritation but to enucleate. Pain set in in the other eye, which was relieved by broad iridectomy. He believed that when, at the earliest indications of sympathetic irritation, enucleation was made without preventing trouble, we should be taught not to wait for this irritation before operating.

Dr. Seely, of Cincinnati, said that he was glad to find that the gentlemen in this discussion repudiated the idea of an occult sympathy as causing this trouble, such "sympathy" being formerly a term to cover ignorance, and unwarranted by any analogy in pathology or medicine. It was not *sympathy*, but *transmitted disease*. In speaking against the needless removal of an injured eye, Dr. Little had exactly expressed his views. An eye might see well enough to guard its possessor against danger from a coming carriage, etc., though not capable of more distinct vision.

Dr. Carl Seiler, of Phila., then read a paper on the

USE OF MINERAL WATERS IN CATARRHAL AFFECTIONS OF THE MUCOUS MEMBRANE OF THE UPPER AIR-PASSAGES.

There are at Cresson three springs. 1. One a very strong iron spring, which, according to the analysis made by the Pennsylvania State Survey, ranks with the best so-called steel springs of Europe. 2. A ferruginous alum spring and a weak magnesia spring. These waters he used on a number of patients suffering from chronic catarrhal inflammation of the upper air-passages in the form of sprays applied locally to the diseased mucous membrane, and the iron and magnesia waters internally with proper regulation of the diet of the patients. He found that the ferric alum water had a decided tonic and stimulating effect in those cases of atrophic nasal catarrh which were complicated with pharyngitis sicca and chronic laryngitis, and that the beneficial effect of the local application was very soon apparent.

The iron water he found to have no very decided effect upon these cases, but to be of great value in cases of follicular pharyngitis, and in the milder forms of hypertrophic nasal catarrh, as well as in cases of ordinary simple chronic laryngitis and bronchitis. The magnesia water locally applied gave no results whatever, but he found it a valuable adjuvant in the treatment of patients suffering from lythæmic inflammations of the mucous membrane of the upper air-passages. In these cases the patients were directed to drink the water freely, and its slightly diuretic effect soon became apparent. The iron spring also is somewhat diuretic in its action, but is chiefly valuable as a tonic, particularly in cases with feeble digestion.

The Chairman here said that it was his painful duty to announce the

DEATH OF DR. SAMUEL D. GROSS.

After a resolution expressive of their sense of the loss thus sustained, the Section adjourned.

Section on Obstetrics and Diseases of Women.

The Section met at 2.30 P.M., The Chairman, Dr. T. A. Reamy, of Cincinnati, presiding.

Dr. R. S. Sutton, of Pennsylvania, presented a paper on

DESPERATE SURGERY AMONG WOMEN; THE PROPER FIELD FOR IT; WHO SHOULD AND WHO SHOULD NOT ATTEMPT IT.

Desperate surgery, he said, means operations endangering life, and in women it is chiefly intra-abdominal. Its dangers are not to be denied, as is shown by American statistics. The proper place for these operations is not in the general hospital with its pus-soaked walls, or the modern dwelling with its defective sewage, or roadside cottage with its health-bringing air; there cannot be found the indispensable nurse, and the surgeon may be a league away. These conditions render such a locality unavailable.

The material elements of safety are: Large airy apartments, no zymotic germs, sun and air space, perfect sewage, quiet city neighborhood, a conscientious nurse, but necessarily a trained one, and the surgeon near his patient. All of these conditions are secured in a private hospital, and with them we can equal the success of Keith or Tait, by whom they are practised. Statistics show that the best results are obtainable in a private or special hospital.

The general practitioner who is exposed to the poisons of scarlatina, diphtheria, and erysipelas, is not warranted in assuming the responsibility of these operations, and by so doing destroys life and makes himself liable to criminal prosecution. The obstetrician encountering puerperal peritonitis and other zymotic diseases, has no right to imperil a woman's life. The gynecologist may be the minister of death whilst attending a case of uterine cancer. The clothing of the practitioner from exposure to infective diseases may be the deadly agent. The history of the past and the judgment of the present decide the operator to be a specialist, and exclude him from general practice. Dr. Sutton concluded with the assertion that, for successful abdominal surgery, the absence of all zymotic disease poison, and the presence of perfect cleanliness and good nurses are essential.

Dr. Engelmann, of St. Louis, then spoke of the importance and difficulty of blending theory and practice. He thought that Dr. Sutton's views are theoretically true. The late Dr. Hodgen, an acknowledged able surgeon, lost most of his ovariotomies. He attributed it to the fact of his having at the same time practised general surgery and medicine. He thought that the chief law of success—"absolute cleanliness," was necessary; and that it was best carried out in a private hospital. He had seen an influx of sepsis, apparently from the presence of a single gentleman at an operation, conveyed to the patients that had been and were operated on in a hospital where the most severe abdominal operations had resulted previously in but a slight or no rise of temperature. Dr. Engelmann insisted on the greater value of a "cleansed" than of a trained nurse.

The specialist endangers the success of his operations when he must take the general practitioner as his assistant. If the specialist can achieve absolute cleanliness, he must do it. Even in the English hospitals there remains much to be improved. The private hospital of Dr. Martin is by no means a model one, and he thought his success had been due entirely to skill and cleanliness. Dr. Martin's new hospital is to have a room for major and one for minor operations, and will be so constructed as to be easily flooded, when necessary, with a proper disinfectant.

DR. DUNLAP referred to his experience of over forty years, and said that, theoretically, the statements contained in the paper are true. One of the main factors of success had been, however, omitted. This is the condition of the patient's mind when removed from her home and left in a hospital. He insisted on the importance of the woman's conviction of recovery after the operation, and did not think the practitioner a walking magazine of death and destruction; yet he is careful of cleanliness, the value of the purifying influence of the air in removing the poisons of infectious diseases that may have penetrated the clothing. During 1881–2, almost every one of his ovariotomies died. He lost three cases in succession. Since March, 1883, he has operated twenty-two times, with but two deaths. One of these was in a woman of seventy years; the other, sixty-four and broken down. He is particular to thoroughly clean the wound, and treat his hands and instruments in the same manner. He favors the semi-reclining posture for the patient, which is of great importance for drainage. He does not favor the use of carbolic acid in the abdominal cavity, because it prevents the natural absorption of poured-out fluids; at the same time it often interferes with healthy kidney action.

In answer to a question as to the cause of the severe mortality mentioned, he said that he thought it due to atmospheric influences passing over areas of country. His other operations in general surgery had been also unfavorable at that time.

At 3.40 P.M., the

DEATH OF DR. S. D. GROSS

was announced, and, in honor to the memory of the great surgeon, the Section took a recess.

Upon reconvening, DR. QUIMBY, of Jersey City, referred to the two extremes of treatment and precaution advised in this operation. He takes a middle ground. Believing want of cleanliness one of the greatest dangers, he does not consent to set these operations apart as the work of special persons. During an epidemic of smallpox, he had attended cases of confinement with the only precaution of changing the clothing, and attending his obstetric patients last. Cleanliness of hands and hair was also practised, and he failed to observe any disastrous results.

In reply to an inquiry of Dr. Sutton, he said that he had opened the abdominal cavity six or seven times, with a mortality of three.

DR. SUTTON, in conclusion, said that the statement of the low foreign mortality and its causes had not been refuted. His own first seven cases were fatal. After having observed the practice abroad for eighteen months, and having again had four failures in succession, he perceived his error and opened a private hospital. His seven ovariotomies therein performed have all been successful, and his highest temperature rise has been 101.5 F.

DR. J. TABER JOHNSON, of Washington, then read a paper on

THE EFFECTS OF TRACHELORRHAPHY.

He wished to draw attention to the immediate and the remote effects of the operation.

In some cases the operation is unwisely or unskilfully done, or oftener than is needed. Emmet now does one operation where formerly he would have done ten. This is because he first attempts the cure of endometritis or endocervicitis. In having the unfortunate result of a complete stenosis of the cervix, the fault is with the operator, not the operation. The frequency of laceration is not increased. When the operation is indicated and well performed it is one of the greatest operations of the age.

DR. GARCELON, of Maine, endorsed several of the author's points. The operation has no effect on pregnancy and conduces to fertility. There are two important reasons for performing the operation: 1. It reduces uterine hyperplasia; he operates in all cases of increased growth whether a laceration exists or not. 2. The scissors must be very sharp; one cut for each side suffices. 3. The parts must be absolutely approximated.

DR. WOODWARD, of Vermont, avoids pelvic cellulitis by digital examination; if on any part of the vaginal surface tenderness is produced, he does not draw the neck towards the vulva, as is usually done, but operates with it *in situ*.

THE CHAIRMAN, DR. REAMY, said that we ought to operate in all perceptible lacerations, and do so without awaiting the appearance of symptoms. Epithelioma is seen in its frequency and analogous causation on the lower lip of men. He was of the opinion that Emmet is forsaking his most brilliant operation.

WEDNESDAY, MAY 7TH—SECOND DAY.

The Association was called to order at 10 A.M., by the PRESIDENT, who announced, in affectionate terms,

THE DEATH OF DR. S. D. GROSS,

and appointed the following committee to consider and report what action should be taken by the Association thereon: Drs. T. G. Richardson, of Louisiana; L. A. Sayre, of New York; J. H. Packard, of Philadelphia; F. H. Hamilton, of New York; Moses Gunn, of Chicago; W. T. Briggs, of Nashville; and I. Minis Hays, of Philadelphia.

THE PRESIDENT then announced the following as the committee to consider the propriety of inviting to meet in the United States in 1887

THE INTERNATIONAL MEDICAL CONGRESS:

Dr. J. S. Billings, of U. S. A.; Dr. L. A. Sayre, of New York; Dr. R. H. Fitz, of Mass.; Dr. I. Minis Hays, of Philadelphia; and Dr. H. F. Campbell, of Georgia.

Also the following

COMMITTEE ON THE RECOMMENDATIONS CONTAINED IN THE PRESIDENT'S ADDRESS:

Drs. N. S. Davis, W. W. Dawson, W. T. Briggs, T. F.

Prewitt, D. W. Stormont, J. L. Cabell, and H. B. Ransom.

The following were then announced as having been appointed to constitute the

NOMINATING COMMITTEE:

Alabama, Jerome Cochran. *Arkansas*, P. O. Hooper. *California*, F. W. Hatch. *Colorado*, Jesse Hawes. *Connecticut*, G. L. Porter. *District of Columbia*, J. W. H. Longjoy. *Dakota*, H. Galloway. *Delaware*, W. Marshall. *Illinois*, E. P. Cook. *Indiana*, J. B. Haney. *Iowa*, H. C. Huntsman. *Kansas*, F. F. Dickman. *Kentucky*, W. H. Mather. *Louisiana*, T. G. Richardson. *Maine*, F. C. Hayes. *Massachusetts*, Charles H. Savory. *Maryland*, J. S. Lynch. *Mississippi*, B. A. Duncan. *Minnesota*, D. Leassure. *Missouri*, N. F. Essig. *North Carolina*, C. J. P. Hague. *New Hampshire*, S. P. Mercer. *Nebraska*, J. W. Parsons. *New Jersey*, Joseph Parrish. *New York*, J. W. S. Gouley. *Ohio*, W. M. Beach. *Pennsylvania*, J. B. Murdoch. *Rhode Island*, J. H. Eldridge. *South Carolina*, William Huger. *Tennessee*, J. H. Pope. *Vermont*, H. D. Holton. *Virginia*, Alexander Harris. *West Virginia*, George Beard. *Wisconsin*, William Fox. *U. S. Army*, J. R. Smith. *U. S. Navy*, N. S. Bates. *U. S. Marine Hospital*, Walter Wyman.

The report of the Committee on Resolutions to secure more competent

MEDICAL AND SANITARY SERVICE ON BOARD TRANS-OCEANIC PASSENGER VESSELS

was read by A. N. BELL, M.D., Chairman. The report was briefly as follows: After conference, correspondence, and due deliberation, a bill was prepared and introduced by the Hon. Henry W. Slocum. The report referred to the contrast existing between the percentage of deaths on sea during the four years ending with 1873 and the four ending with 1883. During the former period there were 1,064,180 passengers carried, and 1333 deaths, or a percentage of .73 per cent. per thousand of the total number. For the corresponding period ending with 1883, the passengers numbered 1,127,215, the deaths reaching 1558, or .85 per cent. per thousand. This difference of .12 per cent. means that 225 lives would have been saved in the latter period had the sanitary conditions in that period been as good as in the former. In conclusion, he stated that the mortality is now three times as large as it should be, or would be, if the sanitary conditions of vessels were properly provided for.

DR. PRATT, of Michigan, moved that the report be accepted, and the committee be continued, to report one year from the present time.

DR. IRVIN spoke at great length upon the manner in which a similar bill is working in England, where he said that he was the first agitator of the movement.

The report was received and the suggestion adopted.

DR. PRATT then presented the following:

Resolved, That the American Medical Association, now in session, urges upon Congress the necessity of providing suitable legislation to secure the well-being of immigrants coming to this country, and to protect our own public health.

THE ADDRESS IN MEDICINE,

by the Chairman of the Section of Practical Medicine, DR. J. V. SHOEMAKER, of Philadelphia, was then read. The Address was referred to the Section on the Practice of Medicine.

Drs. Battsford and Stevens,

DELEGATES FROM THE CANADA MEDICAL ASSOCIATION,

were invited to seats on the platform.

DR. THADDEUS A. REAMY, of Cincinnati, the Chairman of the Section on Obstetrics, then delivered

THE ADDRESS IN OBSTETICS.

(See p. 530.)

EXPERIMENTAL MEDICINE.

The following resolutions were then presented by Dr. Henry H. Smith, of Pennsylvania, on behalf of Dr. H. C. Wood, of Philadelphia.

Whereas, It appears that an effort is being made to restrict, by legislative action, the practice of investigation in medical science by experiments on animals, and,

Whereas, In the opinion of this Association, such restriction is not needed for the guidance of medical men in their investigations, and would be an injury and a hindrance to the pursuit of knowledge and the improvement of the medical art, therefore,

Resolved, That a standing committee of seven be appointed by the President of the Association, to be known as the Committee on Experimental Medicine of the American Medical Association, charged with the duty of opposing, by all legitimate means, any interference with the progress of medical science by unwise or ill-considered legislation.

DR. KEYSER, of Philadelphia, explained the methods of procedure adopted by the antivivisectionists of his city, and the cards sent to physicians by them.

DR. DALTON, of New York, spoke of the movement in Philadelphia, and showed the absurdity of the position occupied by the antivivisection agitators.

The resolutions were then adopted by a unanimous vote.

THE CHAIR then announced, as the committee called for in the resolutions: Drs. Horatio C. Wood, William Pepper, James Tyson, of Philadelphia; Christopher Johnston, of Maryland; J. C. Dalton, and Austin Flint, Jr., of New York; and J. S. Billings, of U. S. Army.

MEDICAL ADVERTISING.

DR. ATWOOD offered a memorial with reference to the methods of advertising now pursued by our colleges. He said that if it is reprehensible for the physician to advertise, it is equally so for an association of physicians. He claimed that great harm is done by the advertising of free dispensaries, and he regretted deeply that so many men of *inferior* attainments, connected with colleges, succeed in practice above their superiors who are not so fortunate in position. Adopted.

ELEVATING THE STANDARD OF MEDICAL EDUCATION.

A resolution was offered recommending that the colleges all require a preliminary examination of applicants for admission, a course of three years, and a thorough final examination, including tests of skill in

various departments. After some discussion, a motion to lay the resolution on the table was made, but lost. Finally, the resolutions were adopted.

DR. PACKARD, of Philadelphia, moved that the Association take up for consideration, after the addresses for Thursday morning, the

AMENDMENTS TO THE CONSTITUTION

offered and laid on the table at the meeting of the Association at St. Paul, two years ago.

THURSDAY, MAY 8TH—THIRD DAY.

GENERAL SESSION.

The Association was called to order by the PRESIDENT at ten o'clock.

TIME OF ANNUAL MEETING.

DR. KELLER, of Arkansas, called attention to a mistake made by the Secretary. A few years ago when he introduced a resolution leaving the date of the annual meeting at the option of the Association, instead of restricting it to the months of May or June, this resolution had been laid on the table for a year or two, but at the last meeting it was unanimously passed. He had been informed that the Secretary had instructed the Nominating Committee that this resolution had not been adopted. He therefore moved that the Secretary be instructed to correct the mistake.

The Committee appointed at the last meeting to petition Congress to provide a suitable

FIRE-PROOF BUILDING FOR THE SAFE-KEEPING OF THE ARMY MEDICAL MUSEUM AND LIBRARY,

reported that they had presented to Congress resolutions setting forth the present inadequate protection provided for these valuable collections, and asking prompt action on the bill introduced, but no action as yet had been taken. An appropriation of ten thousand dollars per annum was also asked for the support of the library, and five thousand more for the publication of the catalogue. The report was adopted and the committee continued.

DR. GEORGE M. STERNBERG, U. S. A., moved that

"We earnestly petition Congress to make suitable appropriations for the prosecution of scientific researches relating to the

CAUSES AND PREVENTION OF INFECTIOUS DISEASES OF THE HUMAN RACE,

to be expended under the direction of the National Board of Health, and that a permanent detail of one medical officer of the Army and one of the Navy be authorized for the prosecution of researches of this nature.

"*Resolved*, That a committee of five be appointed to present copies of this resolution to the Speaker of the House, to the President of the Senate, and to the Chairmen of the Committee on Public Health of the House and of the Senate." Adopted.

Drs. G. M. Sternberg, I. Minis Hays, A. H. Gihon, J. E. Reeve, and John C. Dalton were appointed as the committee.

DR. KELLER asked attention to a resolution in regard to

CREMATION,

offered by him in Cleveland, and referred to a committee to which was also referred that part of the President's Address regarding the invitation to

THE INTERNATIONAL MEDICAL CONGRESS

to meet in 1887 in this country. The committee reported that they found the sentiment almost unanimous in favor of the invitation. It was therefore recommended that a committee of seven be appointed to present an invitation at Copenhagen, and, if accepted, with power to make all necessary arrangements, and the committee was authorized to draw upon the Treasurer for the preliminary expenses, not exceeding five hundred dollars. They also suggested Washington as the place of meeting.

DR. J. M. TONER presented the

REPORT OF THE BOARD OF TRUSTEES OF THE ASSOCIATION JOURNAL.

The contract for publication had been given to Newell & Co., of Chicago, and by a fortunate coincidence the editor chosen resided in the same city. The *Journal* had been commenced, and although like all new undertakings it had been somewhat trammelled by lack of funds, its good effect had been largely felt in stimulating members of the Association to pay their dues, and in largely increasing the income of the Association. He further believed that the present year would end with a surplus in the treasury. He then called upon Dr. N. S. Davis, the editor, to make his report.

DR. DAVIS reported that arrangements had been made for the publication of the *Journal* immediately after the last meeting, but that on account of unavoidable delays the *Journal* was late in appearing, and was a little late in its issue during the first three months. In accordance with the estimates made last year, 3500 copies were printed at each issue, but before the fourth issue the number was increased to 3800, and had been continued at that rate until the present time. The total weekly circulation is 3436, of which 2171 go to members. Of subscribers for the present year, 650 have paid, leaving 552 who have not paid. It is thus seen that the circulation has considerably exceeded the estimate made. Immediately after the meeting of the Association in Cleveland, circulars were sent to all the medical schools of the country, large drug manufacturing houses, and medical book publishers. In reply, a large number of advertisements was received, but many of them were of such character as to be precluded by the rule adopted by the Board of Trustees. Notwithstanding the restriction alluded to, quite a number of page advertisements were accepted. The income from this source for the first three-quarters of the year was about $1000; and at the end of the fourth quarter it should reach over $1200.

For the first nine months the total income was $10,345. This might be somewhat reduced by losses, etc. The total receipts from subscribers was $2293. On account of the fact that certain subscribers paid but four dollars each, the other dollar being paid to the person securing the subscription, there might be an apparent discrepancy in the figures between the number of subscribers and the amount received therefrom. If all advertisements be paid for, the total receipts would be $18,547.50; the total amount drawn from the Treasurer of the Association for publication purposes was $8171.26; that would make annual expenses $10,891.25, leaving a balance in the treasury of $1650.25

as result of the first year's publication. Deducting therefrom the necessary expenses of the Association, there will be over $500 still left in the treasury. As a result of the publication of the *Journal*, the number of members paying dues had been fully double that of any former year. On account of the need of a weekly journal west of the Alleghanies, a large proportion of the subscribers came from that section.

DR. J. M. TONER then resumed his report. In the opinion of the Trustees, the report of the editor showed the *Journal* to be in a satisfactory condition; it had been conducted with economy, ability, and judgment; the best interests of the Association had been kept in view, and its dignity maintained with rare discretion. It is believed that the experience gained during the past year, with the increased funds, will enable the editor to do better work in the future. If all the available funds were placed in the work of the *Journal*, the result would be seen in an even more satisfactory periodical. Early this year, Dr. Davis had presented his resignation, but after correspondence with the Trustees, he acceeded to their earnest request and withdrew it. Dr. Davis had informed them that while he would do the best he could for the *Journal* during the coming year, at the end of that period he would absolutely resign. Bids had been received for the publication of the *Journal* for the coming year from various firms, but the bid of the present publishers had been considered most suitable, and the publication had again been put in their hands.

DR. JOHN H. PACKARD stated, in presenting a minority report, that in no other way could he fulfil the duty resting upon him as one of the Trustees. He had no intention of reflecting on his colleagues, and was without hostility towards the present editor: he had no desire to hamper an enterprise in which for four years he had been warmly enlisted, and disclaimed any personal motive. From the majority report of the Trustees it would appear that the expenses of publication of the *Journal* had been met. He had, however, in the beginning of this year, received an official letter from the President of the Board in which he stated that the editor had not drawn his salary, and would abstain for some time from taking any; of this he expressed strong disapprobation. It was not only from a financial aspect that he dissented from the majority report. In his opinion the *Journal* has not approached anywhere near the standard to which the organ of the Association should attain. The defects of the *Journal* are not those consequent on a new enterprise, and are not decreasing.

The object of the *Journal* was not merely to journalize the transactions, not merely to spread out the minutes of the Association or papers read. The object is to make a strong, wide-awake, high-toned periodical, well equipped in every respect, to be a medium of communication between members all over the country. A thoroughly trained corps of editors is requisite; access must be had to large libraries, and where there is opportunity to secure auxiliary work such contributions should be liberally paid for. Facilities for mechanical execution are essential to real success. None of these requirements seem to have been possessed. Due respect for the interests of the Association compelled him to state this as his sincere and deliberate judgment. The report concluded by recommending that the resignation of Dr. Davis as editor be accepted, and that the publication office of the *Journal* be transferred to some eastern city, Washington, Philadelphia, or New York.

DR. HYATT then moved that the minority report be laid upon the table. The yeas and nays being called for, the roll was called, and the motion carried by 191 yeas to 74 nays.

A motion to adopt the majority report was then carried.

The Nominating Committee then presented the following list of

OFFICERS FOR THE ENSUING YEAR:

President.—H. F. CAMPBELL, M.D., of Georgia.

Vice-Presidents.—J. S. LYNCH, M.D., of Maryland; D. D. MERCER, M.D., of Nebraska; J. W. PARSONS, M.D., of New Hampshire; H. C. GHENT, M.D., of Texas.

Time and Place of Next Meeting.—New Orleans, on the last Tuesday in April, 1885.

Judicial Council, to fill vacancy, 1886, J. K. Bartlett, M.D., of Wisconsin.

To fill vacancies caused by expiration of term of service, J. H. Murphy, M.D., of Minnesota; J. M. Toner, M.D., of Washington; W. Brodie, M.D., of Michigan; H. D. Holton, M.D., of Vermont; A. B. Sloan, M.D., of Missouri; W. B. Ulrich, M.D., of Pennsylvania; W. M. Beach, M.D., of Ohio.

OFFICERS OF SECTIONS:

Practice of Medicine.—H. D. DIDAMA, M.D., of New York, *Chairman;* G. M. GARLAND, M.D., of Massachusetts, *Secretary.*

Obstetrics.—R. S. SUTTON, M.D., of Pennsylvania, *Chairman;* J. T. JELKS, M.D., of Arkansas, *Secretary.*

Surgery.—DUNCAN EVE, M.D., of Tennessee, *Chairman;* E. B. KING, of Pennsylvania, *Secretary.*

Ophthalmology.—JOSEPH A. WHITE, M.D., of Virginia, *Chairman;* EUGENE SMITH, M.D., of Michigan, *Secretary.*

Diseases of Children.—JOHN H. POPE, M.D., of Texas, *Chairman;* S. S. ADAMS, M.D., of District of Columbia, *Secretary.*

State Medicine.—E. W. SCHAEFFER, M.D., *Chairman;* J. M. MCCORMICK, M.D., of Kentucky, *Secretary.*

Oral and Dental Surgery.—A. W. HARLAN, M.D., of Illinois, *Chairman;* J. EWING MEARS, M.D., of Pennsylvania, *Secretary.*

Trustees of Journal.—H. F. CAMPBELL, M.D., of Georgia; J. H. PACKARD, M.D., of Pennsylvania; LEARTUS CONNOR, M.D., of Michigan.

Necrology.—J. M. TONER, M.D., of District of Columbia, *Chairman.*

The report of the standing Committee on Meteorological Conditions was presented by DR. N. S. DAVIS, Chairman.

THE AMERICAN SURGICAL ASSOCIATION.

Fifth Annual Session held at Washington, April 30, May 1, 2, and 3, 1884.

(Specially reported for THE MEDICAL NEWS.)

THURSDAY, MAY 1ST—SECOND DAY.

THE Association was called to order at eleven o'clock.

Reports of Committees being in order, DR. JOHN H. PACKARD presented the

TREASURER'S REPORT,

which showed a balance on hand of $1325.25.

THE END-RESULTS OF EXCISION.

DR. P. S. CONNER then offered the following:

Resolved, That a committee of three be appointed to obtain, so far as may be possible, reports relative to the end-results of excisions made for gunshot injury during the late war.

In the absence of DR. S. W. GROSS, of Philadelphia, his paper on

GASTROSTOMY, ŒSOPHAGOSTOMY, INTERNAL ŒSOPHAGOTOMY, COMBINED ŒSOPHAGOSTOMY, ŒSOPHAGECTOMY AND RETROGRADE DIVULSION IN THE TREATMENT OF STRICTURES OF THE ŒSOPHAGUS,

was read by Dr. J. Ewing Mears, and will be published in full in an early number of THE MEDICAL NEWS.

Dr. HENRY F. CAMPBELL, of Georgia, said that the paper was the best *résumé* upon the subject of operative measures in the treatment of œsophageal obstructions which we possessed. In his opinion, strictures of the œsophagus are, as a rule, not cicatricial, but tetanic from spasmodic contraction of the muscular fibres. Even in strictures produced by caustic alkalies, the cicatricial formation is exceedingly superficial, and the constriction depends mainly upon the muscular contraction excited by the irritation of the stricture. In order to dilate a contraction of this kind, the œsophagus must be taken by surprise. A large ball on the end of a whalebone only excites a more energetic contraction, but if a soft "rat-tail bougie" is passed down it acts somewhat as would a bolus of food. Almost immediately after the passage of a small bougie of this kind, fluids can be taken. Then after daily treatment in this manner for a week, a larger size of bougie may be used. A number of bougies of the pattern used by the speaker were exhibited.

In reference to the results of gastrostomy, he did not think the statistics very flattering, and he believed it better to allow the patient to die without undergoing this operation, since death is inevitable.

DR. JOSEPH W. THOMPSON, of Paducah, Ky., then read a paper on the

SURGERY OF THE HAND, ESPECIALLY AS APPLIED TO RAILROAD INJURIES.

He first spoke of the great importance of the hand, both in its function and as a means by which the intellect and genius of man is perfected. The progress which is being made in machinery carries with it increased perils to the hand, making it important that we should possess a thorough knowledge of the anatomy and surgery of that organ. Every resource of investigation should be brought to bear, in order to establish a conservative practice.

Attention was then called to the *inflammatory affections* of the hand, and the importance of prompt and free incision where swelling and effusion require it.

Wounds of the palmar arches are among the most difficult injuries we have to contend with. In this regard, the propriety of cautiously enlarging the wound so as to secure the injured vessels was discussed, and the importance of acute flexion of the forearm upon the arm was insisted upon. In *caries*, a free incision down to the bone will usually suffice; in necrosis, the detached portions of bone must be removed.

Resection of the metacarpal bones has proved a successful practice, especially when carried only to the extent of removing fragments of bone and smoothing sharp ends. Resection of phalanges, except of the distal row, is seldom admissible. In other cases, amputation is preferable. Excision of the carpal bones is of doubtful propriety, and can hardly be considered an established operation.

In amputation of the thumb, forefinger, and little finger, the stump should be made as long as possible, but a more useful hand is left by removing the middle and ring fingers at the metacarpo-phalangeal articulation. In this connection the essayist reported two cases of incised wounds, in which the hand was almost severed, and exhibited photographs illustrating the almost perfect repair attained in the functional movements.

In conclusion, antiseptic treatment of the hand was discussed. The author stated that in his experience, both as chief surgeon to the Chesapeake and Ohio and Southwestern Railroad, and in his private practice, he had found the properly applied antiseptic dressing act not only so as to prevent fermentation in the wound, but also as an anæsthetic, rendering the use of opiates usually unnecessary. It is his practice to use, for the first two dressings, about a two per cent. aqueous solution of carbolic acid, then to envelop the hand in absorbent cotton saturated with a ten per cent. solution of the acid in olive oil; a roller bandage being applied over this, and the dressing allowed to remain undisturbed from six to ten days.

In order to bring the subject of hand injuries more fully before the Association, the President called for the paper, by DR. JAMES MCCANN, of Pittsburg, entitled

CLINICAL OBSERVATIONS ON SEVERE RAILROAD INJURIES OF THE EXTREMITIES,

He referred to the variations in form and degree of the shock following injuries to different portions of the body. Attention was also called to the importance of not being deceived by the apparent cessation of the hemorrhage after a crushing injury, for the apparently slight oozing is often sufficient greatly to prolong shock or even cause death if uncontrolled.

Railroad injuries of the extremities were divided into two classes; the first comprising injuries involving skin, fascia, muscles, and bones, the nerves and larger blood-vessels escaping serious damage; the second including cases in which the nerves and vessels are all damaged, and the integrity of the limb destroyed. In injuries near joints the gravity of the case is greatly increased, also by its involving the joint, though never so slightly. Wounds of the elbow and wrist are, however, an exception to this rule, and even severe injuries to these joints may be well recovered from. Although there must be exceptions to all rules, it is generally best to use every effort to preserve a limb, regardless of the extent of the injury, if the arterial pulsation can be felt in the extremity, but if this is lost and the hemorrhage is arterial, it is better to amputate at once. Attention was called in this connection to the fact that a limb may be com-

minuted so as to necessitate amputation without any apparent injury to the integument having been sustained. In the management of these injuries the indications are first to arrest the hemorrhage. For this the tourniquet should *never* be applied. Various other methods were recommended. All wet or soiled clothing should be removed. The patient should be covered with warm blankets, the head placed low, and perhaps the foot of the bed elevated, and, if shock is severe, brandy or the aromatic spirit of ammonia administered. Transfusion may be necessary. The wound must be thoroughly cleansed and closed, or dressed open according to the requirements of the case.

The question of primary or secondary amputation, the author believed to be, as a rule, capable of the same decision as in military surgery, viz., the primary is preferred, but cases differ to a great extent in this regard. He was of the opinion that an attempt should be made in every case of comminution to save life by amputation, no matter how small the chance of recovery, unless it would positively lessen the chances. No such rule as that formulated by Erichsen can be relied upon—abandoning to death all adults suffering from a form of injury necessarily fatal without amputation. No rule can be laid down to govern the mode of amputation. It should, however, be early and rapid. All living tissue should be saved. Disarticulation at shoulder or hip is unjustifiable. In support of the value of immediate amputation, the author appended a table of the statistics of the Western Pennsylvania Hospital, from January 1, 1877, to December 31, 1883, including one hundred and twelve amputations for railroad injury.

A large number of cases were reported somewhat in detail, and appendices were added to the paper showing the nature of injuries most common, their treatment, and the results in different parts of the United States.

Before proceeding to the discussion of these two papers, the President called for remarks by Dr. Nancrede, as a close of the discussion of his paper on

SURGICAL INTERFERENCE IN CEREBRAL ABSCESS.

DR. NANCREDE stated that there were but two or three points to which he wished to call attention. One was that, in all the cases he reported, a normal, or even a subnormal, temperature invariably accompanied the formation of a cerebral abscess; and where the abscess was cranial, but not cerebral, or, in other words, was secondary to some other intracranial inflammation, as a circumscribed arachnitis, we have an elevation of temperature; but even in these cases, when the brain substance became involved, the temperature at once fell to the normal degree, or beyond it.

Then, again, he was not aware that the aspirator-needle had heretofore been pushed into the brain substance, where pus was not discovered, by mere section of the dura mater; and although in his case he did not succeed in withdrawing pus by the aspirator, it came up through the opening left after withdrawal of the needle, and relieved the immediately dangerous symptoms. In reference to the case reported by Dr. Campbell, in which respiration ceased immediately after, and apparently in consequence of, the evacuation of a large abscess, he said that there are so many ways of performing artificial respiration that he was reluctant to agree with the former speaker in regard to the cause of death.

In concluding his remarks, the speaker stated that he saw no reason why brain abscess could not be treated just as ordinary subcutaneous abscess with fair result. One such case, he said, had been reported by Dr. Brinton, of Philadelphia. Brain abscesses sometimes exist a long time without proving fatal. An important fact in this connection is that, although the result of operative interference is not as good as could be desired, yet there is no such thing as a recovery without surgical interference.

DR. JOHN H. BRINTON, of Philadelphia, stated that the case referred to by Dr. Nancrede was that of a young man who had his skull fractured by an accident while coasting. The bone was somewhat comminuted. He trephined and removed the fragments. The case did well for a few days; then symptoms of compression arose. He had the impression at the time that abscess was forming. The temperature was normal or slightly subnormal. In order to relieve the symptoms of compression, and, if possible, give vent to the pus, he laid open the dura mater, by a free crucial incision opposite the opening made by the trephine. He did not introduce a probe. This operation he made at two o'clock; at three or four, violent convulsions set in, and continued until eight. At the expiration of that time, a copious discharge of pus occurred from the wound. For some time, it gradually increased in quantity, and became thicker. After a few days, the symptoms subsided, and the boy made a complete recovery.

A discussion of the papers on

RAILROAD INJURIES OF THE HAND

was then called for.

DR. T. F. PREWITT, of St. Louis, agreed with the statement that in amputations of the hand, as much as possible should be saved. There seemed a little incongruity, however, between this statement and that made in regard to the middle and ring fingers. Sometimes it is very difficult to decide what course to pursue.

DR. L. MCLANE TIFFANY said that an amputation at the first phalangeal joint left, as a rule, a useless stump. But this might easily be avoided by simply stitching the divided tendon into the wound of the integument. Union occurred by granulation, and the union of the end of the tendon with the cicatrix gave fair movement of the finger.

DR. B. B. BONTECOU remarked that it made but little difference how much the fingers are mangled; they can be saved provided there is an artery and a vein left to carry on the circulation. He also spoke of the importance of making deep incisions, in order to relieve the embarrassment of the circulation where the return of venous blood was interfered with.

DR. D. MACLEAN, of Detroit, thought the expedient of stitching the tendon into the wound a good one in many cases, but he doubted whether a stump of this kind would be in reality of much more use than otherwise. He had never seen a patient with much motion of a stump, and the usual complaint is that they are painful or otherwise troublesome. He had several times reamputated stumps simply because they were too long. In regard to the ligation of the radial or ulnar artery, he said that such a procedure is almost never necessary, compression answering every purpose.

DR. P. S. CONNER made it a rule, he said, never to make a primary amputation of the hand, no matter what

the extent of the injury may be, and in so doing he believed much could be saved that would be otherwise lost. Where a distal phalanx can be saved by the removal of the bone, it should be saved. In the case of laboring men, more service can sometimes be rendered by amputating regardless of appearance at the metacarpo-phalangeal articulation, but if the patient is a head-worker, a more æsthetic operation is to remove the metacarpal bone also.

DR. NANCREDE spoke very favorably of the use of a solution of the bichloride of mercury as an application to lacerated wounds, especially on account of its antiseptic powers. He reported several cases in which its use had enabled him to save limbs that would have otherwise surely been lost.

DR. H. F. CAMPBELL strongly recommended the ligation of the main arterial trunk as a means of preventing inflammation and swelling.

DR. E. H. GREGORY, of St. Louis, agreed with Dr. Thompson that flexion of the limb was not sufficiently resorted to for the arrest of hemorrhage. He had been in the habit for years of relying largely upon it. To arrest hemorrhage, he said, it is not necessary strongly to flex the limb, but only enough to compress partially the vessel. The pulse at the wrist should not be made to disappear. His method is partially to flex the arm, then to bind it to the chest, as for a fracture of the clavicle, with adhesive strips and a roller bandage.

DR. JOHN H. PACKARD, of Philadelphia, related the case of a man who was twisted around a shaft in such a manner as to produce an injury very closely resembling a railroad injury. The arm was badly mangled and the skin torn from the shoulder so as to render the formation of flaps impossible. Thinking it not right to permit the man to die simply because he could not make an amputation *secundum artem*, he decided to amputate at the shoulder-joint. The flaps were made as if the integument were present. The skin was then drawn as closely as possible and the wound granulated, resulting in a good recovery. He did not believe that enough cicatricial tissue was present to give any great inconvenience, although there would probably be an occasional ulceration for some time to come.

DR. W. W. DAWSON called attention to the value of morphia hypodermatically administered to counteract shock, stating that he always relied upon it and thought it preferable to alcoholic stimulants. He also inquired whether Dr. McCann had made use of elastic compression to keep down inflammation and swelling.

DR. MCCANN stated that he had been accustomed to the hypodermatic use of morphia to relieve pain, but had not used it in large doses or directly with a view to prevent or relieve shock.

DR. JOHN H. BRINTON, of Philadelphia, then read a paper entitled

A REPORT OF TWO CASES OF INTRAUTERINE FRACTURE, WITH REMARKS ON THIS CONDITION, AND REFERENCES TO FIFTY-ONE CASES ALREADY REPORTED.

He stated his belief that the accident referred to was of more common occurrence than is generally understood. The first case reported was that of a strong, healthy, farmer's wife, aged twenty-five, who gave birth at term to a female child, being delivered with forceps. The right leg of the child was deformed. In the fifth month of her pregnancy the mother had fallen, striking on her right side. Two or three weeks later she had a more severe fall. After neither fall was there any hemorrhage, but she complained of great pain on the right side of her abdomen after the second fall. The right leg of the child was shorter than the other at birth. The deformity was greatly relieved by a subcutaneous division of the tibia and adjustment of the fragments.

The second case was that of a woman thirty-five years of age, who, when eight months gone, struck her abdomen forcibly against a tub-handle. She was delivered at full term of a child, with unmistakable evidence of an overlapping fracture of the clavicle.

He held that in all cases in which the deformity is great relief should be attempted by surgical means.

DR. MACLEAN inquired whether injuries to the mother, severe enough to produce intrauterine fracture of the limbs of the fœtus, were ever so severe as to produce abortion.

DR. GREGORY stated that there was in the St. Louis Medical College Museum, the skeleton of a fœtus in which *every* bone has been fractured, partial ossification of the fractures having occurred later.

DR. BRINTON stated that a number of such cases are on record, but that he had omitted them in his report, inasmuch as they were believed to be due simply to imperfect ossification.

DR. N. SENN, of Milwaukee, then read a paper entitled

EXPERIMENTAL RESEARCHES ON CICATRIZATION IN BLOODVESSELS AFTER LIGATURE.

The paper was divided into twenty-four parts or heads, as follows:

1. The history of ligature. 2. Histology of bloodvessels. 3. Intermediate ligature. 4. Immediate or direct ligature. 5. Scarpa's ligature. 6. Double ligature. 7. Momentary ligature. 8. Temporary ligature. 9. Permanent ligature. 10. Aseptic ligature. 11. Thrombosis after ligature. 12. Organization of thrombus. 13. Formation of cicatrix in bloodvessels after ligature. 14. Formation of cicatrix by adhesive or plastic inflammation. 15. Formation of cicatrix from fibrin. 16. Formation of cicatrix from white blood-corpuscles. 17. Formation of cicatrix from red blood-corpuscles. 18. Formation of cicatrix from immigration of corpuscles. 19. Formation of cicatrix from endothelia. 20. Formation of cicatrix from connective tissue. 21. Primary union in bloodvessels after ligature. 22. Experiments. 23. Remarks. 24. Practical suggestions. The experiments upon which the paper was based were made upon sheep, an animal considered by the author preferable to the dog or other animals generally made use of.

Under the head of practical suggestions the following conclusions were drawn:

1. All operations on bloodvessels should be done under antiseptic precautions.

2. Aseptic catgut ligature is the safest and most reliable agent in securing provisional and definitive closure of bloodvessels.

3. A thrombus after ligature is an accidental formation which never undergoes organization, and takes no active part in the obliteration of the vessel.

4. The intravascular or definitive cicatrix is the ex-

clusive product of connective tissue and endothelial proliferation.

5. Permanent obliteration in arteries takes place in from four to seven days; in veins in from three to four days.

6. In ligating vessels in aseptic wounds, the vessel-sheath can be opened freely without compromising the integrity of the vessel tunics, and such procedure renders the operation safer and easier of execution.

7. The double aseptic catgut ligature should be preferred to the single ligature in ligating large arteries in their continuity near a collateral branch, and should always be employed in all operations of tying varicose veins in their continuity, as the safest and most effective measure in producing definitive obliteration.

FRIDAY, MAY 2D—THIRD DAY.

DR. MACLEAN, of Michigan, said that if the conclusions of the preceding paper were correct, many of the views heretofore entertained must be altered. It has generally been considered unsafe and bad practice to ligate the common femoral, even for aneurism, because it was thought impossible to secure the formation of a clot. Now, if Dr. Senn's conclusions are correct, it is not necessary to have a clot formed, but union takes place directly between the walls of the vessel, without reference to the clot.

DR. H. F. CAMPBELL stated his preference for the silk ligature over the animal, saying that he would be afraid to trust the common femoral to a catgut ligature.

DR. H. E. GREGORY, of St. Louis, also expressed his preference for the silk ligature, and he had no doubt that the silk ligature will be absorbed if left long enough. He has seen the loop almost entirely removed by absorption.

DR. W. A. BYRD agreed in the main with Drs. Campbell and Gregory in regard to the security of the silk ligature, but he also used the animal ligature, being careful to get only the best imported article. In amputations, however, he trusted exclusively to torsion, and has not used ligature in an amputation for three years. Listerism had never impressed him deeply.

DR. BILLINGS, U. S. A., remarked that the distinction drawn between animal and silk ligatures was an improper one, inasmuch as silk is an animal product, and was in reality only a better form of animal ligature. It is difficult, however, to get a pure silk thread, because all thread is either dyed or bleached. He thought further that American surgeons ought not to be too severe in their criticisms of Listerism, in the face of the support it receives from surgeons abroad. Nowhere, perhaps, was there so good an opportunity for testing the efficacy of a system of this kind than in the hospitals of St. Petersburg, and there we find that whereas the amputation of even a finger was attended with great danger before its introduction, the very gravest of operations can now be performed with impunity under its use. It is abroad, in those countries which have crowded and filthy hospitals, that its power is best illustrated.

DR. B. A. WATSON said that he had been in the habit of using catgut ligature for the last ten years, and that he trusted it with the same confidence with which Dr. Gregory trusts the silk. He believed that suppuration is, in most cases, the cause of secondary hemorrhage, and not the failure of the ligature.

DR. NANCREDE called attention to the danger of applying too closely the results of experiments on animals to the human subject. For some unaccountable reason the dog was most commonly selected as the subject of experiment, whereas everybody knows that the results of wounds in the dog are vastly different from the results of the same operation on man. The abdomen of a dog if opened will close by first intention and without any great inflammation, while in the human subject the risk of inflammation is very great.

DR. SENN, in closing the discussion, expressed his belief that secondary hemorrhage was nearly always the result of inflammatory changes at the seat of the ligature.

DR. MOSES GUNN, of Chicago, read a paper on

THE PHILOSOPHY OF MANIPULATION IN THE REDUCTION OF HIP AND SHOULDER DISLOCATIONS,

in which he first reviewed the method proposed a third of a century ago by Dr. Reid, of Rochester, New York, and explained the mistake made by those who supposed that Dr. Reid's method was not new. It differed from former methods in being not merely a method of manipulation, but a definite plan of manipulation. Just what the method was, however, does not seem to be well understood. The manipulations are often practised somewhat vaguely, without a clear conception of the nature of the difficulties to be overcome; and it was to the consideration of these difficulties that the author now gave attention. He emphasized the statement of Dr. Reid that, even in operating upon the cadaver, with the muscles all loose, a part of the capsular ligament was torn away in reducing a dislocation of the hip, and stated that he had called attention to the fact that the resistance given by the untorn portion of the ligament was the great factor in the hindrance of a reduction of this dislocation. A number of cases were reported in this connection, and this rule given for the reduction: For the easy reduction of a dislocated hip or shoulder, the limb should be placed in, as nearly as possible, the same position as that which most frequently characterizes it at the instant of escape.

DR. DAWSON, in opening the discussion, said that it had always been a matter of wonder to him whether the capsular ligament was really torn or only stretched. In old cases, like one that Dr. Briggs had told him about a few minutes before, in which the hip was dislocated for eleven months, what was the condition of the ligament at the end of that time? Was it still torn? It seemed to him that much more frequently the capsule yielded and did not tear. He then reported the case of a little boy upon whom he had tried every method conceivable to reduce a dislocation of the hip, but failing, decided upon making a subcutaneous division of the capsular ligament, as suggested by Dr. Frank H. Hamilton. He introduced a rather small knife, cautiously and gently, but scarcely had it touched the ligament when it snapped. This necessitated an enlargement of the opening in order to remove the broken knife-blade. This done, he severed the ligament and reduced the dislocation without difficulty. He was, however, unable to retain the bone in place, and the child died a few days after, apparently from exhaustion.

DR. BRIGGS, of Nashville, reported more fully the case which had been referred to.

Dr. P. S. Conner, of Cincinnati, inquired whether the author of the paper had ever made a post-mortem examination of a hip-joint soon after the occurrence of a fracture? His reason for asking was that his attention had been called a few years ago, when reviewing the subject, to an article by Adams, who showed that it was only necessary to have the head of the bone slip out over any part of the capsular ligament to produce any form of dislocation with which we are acquainted. The bone is therefore most liable to slip out at the weakest point of the capsular ligament, and this point we find in the inferior anterior portion, where the bony rim is almost entirely wanting. He had satisfied himself by experimentation that after allowing the head to slip out at this point, it was possible to produce any of the various forms of dislocation. He could understand very well how a button-hole rent could let the head of the bone out in young children, but he could not comprehend such a condition in the adult.

Dr. Gunn replied that he had never had the opportunity to see a post-mortem examination of a hip-joint soon after a dislocation had occurred, and he did not believe it possible to get the head of the bone out of the hip-joint by passing it over the capsule without tearing the ligament.

Dr. Pancoast stated that he had proved conclusively to his own mind that it is impossible to stretch the capsular ligament. The ligaments about the hip-joint are not only placed so as to hold the bones in position, but they are reinforced in such a way as to prevent the least possibility of stretching. They are composed almost entirely of white fibrous tissue with only a trace of yellow fibres, as if for the purpose of preventing the possibility of any yielding.

Dr. George W. Gay, of Boston, read a paper on

TRACHEOTOMY IN CROUP,

in which he first referred to the difference of opinion that prevails in the minds of leading surgeons with reference to the advisability of the operation in membranous croup. All kinds of treatment have been followed by such bad results that many surgeons considered operative procedure unjustifiable. In the opinion of the author, however, every chance should be given the patient, and he believed that if the operation were more frequently performed the benefit would, in the long run, far outweigh the evil. He then endeavored to show from the records of the Boston City Hospital for the last twenty years, and from other sources, that the results of the operation were not so unsatisfactory as they have been supposed to be, and that many more can be relieved by timely resort to tracheotomy. The term croup he used in its genuine sense as meaning an acute laryngeal obstruction to respiration due to the presence of a false membrane, with two varieties, the membranous and the diphtheritic. Much of the doubt that is entertained in regard to the justifiability of tracheotomy is due to the confusion of these two forms. Prominence was given to the symptoms, glandular enlargement, nasal discharge, and albuminuria, as of value in the diagnosis of the diphtheritic form. He believed not only in an acute, non-contagious membranous form of croup and a similar contagious form, but also in a form often fatal in which no membrane was formed. After reviewing the literature of the subject in regard to the mortality with and without operative interference, the following reasons were given for its use:

1. The disease is always dangerous, and very often fatal.

2. The results obtained from medical treatment alone are extremely unsatisfactory.

3. Tracheotomy gives more relief, and saves more lives, than any other method known to the profession.

4. It seldom hastens death, and still more seldom causes it.

5. Finally, it affords the friends the great and lasting satisfaction of knowing that everything possible has been done for the patient.

Dr. Pancoast inquired in regard to Dr. Gay's method of cutting through the thyroid isthmus, and also whether he had ever excised a piece of the trachea, instead of inserting a tube, stating that he had pursued that method in a number of cases.

Dr. Tiffany spoke in favor of the use of anæsthetics in this operation, believing ether the best agent for the purpose. He had, in one or two cases, resorted to the excision of a piece of the trachea. He considered a definite diagnosis between the forms of croup out of the question.

Dr. Dawson stated that it had been his custom to operate almost entirely without hemorrhage. After incising the skin, he literally scratches his way down through the tissues with a blunt, grooved director, until the trachea is reached.

Dr. L. A. Sayre, of New York, complimented the author upon his recommendation to blow air into the trachea by means of a tube passed beyond the seat of obstruction instead of trying the dangerous expedient of sucking the membrane out. He also narrated a case which he had met many years ago in crossing the plains. A child was dying from croup. By covering the upright posts of the bed with a quilt, and passing steam under it, he was able to give the child a steam bath, and saved its life.

Dr. Fifield, of Boston, believed there was another factor to be considered, inasmuch as the diphtheritic membrane, no matter how severe the symptoms may be during life, is not found entirely to fill the trachea after death. He recollected having seen his father open the external jugular vein in several cases of croup with excellent result. He further remembered having submitted to the same operation at his father's hand, when suffering from that disease in boyhood. The venesection, he said, was followed by a free expectoration of the membrane.

Dr. Tiffany stated that he had once opened a trachea which was completely occluded by the membrane, the child having expired a few minutes before.

Dr. Gay closed the discussion with the statement that he had never excised a portion of the trachea, and did not favor the method. He used to scratch his way to the trachea, but had come to pay less regard to the hemorrhage, as he had never seen it severe.

On account of the absence of Dr. John S. Coleman, of Augusta, the Secretary read the conclusions drawn in his paper on

THE MULTIPLE WEDGE PRINCIPLE IN THE TREATMENT OF ORGANIC STRICTURES OF THE URETHRA.

The conclusions were as follows: 1. In the treatment

of organic strictures of the urethra, urethrotomy, whether internal or external, and also the method by divulsion, are attended by serious risk to the patient on account of hemorrhage, pyæmia, and uræmia. 2. Strictures treated by these methods are no less liable to recurrence than those treated by gradual dilatation; indeed, unless followed by persistent dilatation, they are subject to early relapse. 3. That gradual dilatation, although slower, is almost free from danger, permanent in its result, and on the whole the best method. 4. The multiple wedge principle devised by the author, viz., that of introducing side by side and one at a time successively a number of filiform bougies, whether applied to the interrupted or the continuous method, offers the easiest, safest, and best method for effecting the solution or absorption of the inodular tissue, and for removing the obstruction.

DR. SAYRE stated that the method described in the paper had been in use for a number of years in the hospitals of New York, but that he was not aware until now that it had been introduced by the author of the paper.

DR. PANCOAST stated his preference for urethrotomy, and exhibited a urethrotome which he highly recommended for the ease with which a stricture could be located and incised by its use.

DR. J. EWING MEARS, of Philadelphia, then read

A CONTRIBUTION TO OUR KNOWLEDGE OF THE PATHOLOGY OF TRIFACIAL NEURALGIA, WITH THE REPORT OF A CASE IN WHICH THREE INCHES OF THE INFERIOR DENTAL NERVE WERE EXCISED.

An examination of the literature relative to neuralgia of the fifth nerve, he said, has shown that in those cases in which resort has been had to the employment of surgical procedures as methods of treatment, no investigations, or, if any, very imperfect investigations, have been made to determine the character of the pathological changes which have been present, and upon which the morbid conditions have been founded. He therefore submitted the report of a case in which free neurectomy was performed and in which a careful study was made of the diseased structures removed.

The patient, a German, aged fifty years, had consulted him eight years and a half preceding the time of operation for an intense neuralgic pain involving the left inferior dental nerve. She soon passed out of his care. The methods of treatment prescribed by various physicians failed, and four years later she again consulted him. He now proposed neurectomy to the patient, but she declined and again sought other advice. At the expiration of four years more she again returned, and expressed readiness to submit to an operation. The disease had now assumed the epileptic form, the paroxysms occurring at intervals of a quarter and half a minute. The operation was done, and three inches of a somewhat swollen and reddened inferior dental nerve were removed. The patient was permanently relieved, and the wound healed promptly.

The author then gave the result of experiments showing the area of distribution of the nerve removed, indicated by complete anæsthesia, slight swelling, and a slight increase of surface temperature, and a photograph was exhibited having the anæsthetic area delineated in ink. The portion of nerve removed was hardened, and longitudinal sections of it made. Lithographic prints of these sections were also exhibited, showing the pathological changes consequent upon the disease. These consisted in some increase of connective-tissue sheaths investing the fasciculi as well as of the trabeculi dividing them, and a change in their regular arrangement. Here and there scattered through the connective tissue are minute yellowish-white dots, the significance of which has not been determined, but it is believed to be a fatty degeneration. The chief changes were in the nerve-tubes themselves, the axis-cylinder not being well made out. The medullary sheath was swollen. The changes were most marked near the inferior dental foramen.

With reference to the cause of trifacial neuralgia, and in explanation of its frequency in comparison to similar affections of other nerves, he believed it was best explained by reference to the exposed condition of the nerve. The lesion, he further believed, is, as a rule, peripheral—in its origin at least—although it cannot be questioned that central lesions sometimes do produce the affection. The question of the involvement of Meckel's ganglion the essayist did not consider of great importance, since he believed that the involvement of branches connecting with the four cervical ganglia by continuity of structure more likely to occur than any involvement of the ganglia themselves. In conclusion, the various methods of treatment, nerve-stretching, neurotomy, etc., were considered, the author expressing his belief that neurectomy was not only preferable, but imperative.

DR. CHEEVER stated that he had excised portions of the inferior dental and of the infraorbital nerves, but had not been favored with as good results as Dr. Mears. It was the rule in his cases that the pain returned. He had tried also several other operations. One operation he especially asked attention to was cutting of the condyle of the inferior maxillary bone, dissecting up the nerve to the foramen, then drawing it out and cutting it off. In one case he had wounded the middle meningeal artery just as it entered the foramen, but secured it with little difficulty. He did not attack the Gasserian ganglion, but scraped away all the nervous tissue he was able to find in the field of operation.

DR. PREWITT reported a case in which he removed an inch and a half of the inferior dental nerve, giving only temporary relief. He had not yet attempted another operation. The speaker also reported another case, a woman over fifty years of age, who had suffered a long time from severe neuralgia of the right infraorbital nerve. He removed the portion of the nerve found in the orbit, without cutting away any of the bone. She was only partly relieved. Pain returned and appeared in the nerve of the other side.

DR. MACLEAN reported the case of an old gentlemen who came to be operated upon, asking to have the nerve exsected. The operation was performed, and the relief has proved permanent for six years.

DR. PANCOAST stated that he had had a great deal of experience in cutting out nerves, with generally good success. He referred to an expedient which his father had used, viz.: drawing the nerve out as far as possible, so that when cut the stump would be drawn in beyond the point of compression in the bony canal.

DR. DAWSON reminded the Association of the cases

he reported during the discussion of a similar question last year in Cincinnati.

DR. HUTCHINSON reported a case in which he had tied the common carotid artery for a neuralgia which resisted all other procedures attempted, with the result of giving immunity from the disease for four years.

DR. MEARS, in closing the discussion, stated that his object in writing the paper was chiefly to get points that had been observed by the Fellows in reference to the etiology and pathology of the disease. He did not place much importance upon the operation done in the case reported, because he did not think it would answer in a great many cases. In order that the disease may be treated more scientifically further investigation of its pathology and etiology is needed, and it was to this end that the author had prepared his paper.

DR. WILLIAM A. BYRD, of Quincy, Illinois, then read a paper on

TREPHINING FOR INSANITY CONSEQUENT UPON A DEPRESSED FRACTURE OF THE SKULL.

After referring to the comparative frequency of the operation of trephining for epilepsy, the result of injury, the author spoke of the few cases in which the operation has been performed for the relief of insanity. He had found, in a careful review of the literature by at least fifteen different authors, the operation mentioned by but one—Gross. Prof. Briggs had performed the operation in three cases.

One case had been operated upon by the essayist, in 1883, for insanity gradually developed as a result of an injury received eighteen years before. The skull was found much thickened. A piece an inch and a half in diameter was removed. She made a good recovery from the operation, but her mental faculties improved for three weeks, then became progressively worse.

Thus, of the four reported cases, one died; one improved for a short time, then became progressively worse; and two recovered. This result, the author believes, indicates that the operation should be resorted to oftener, and very much earlier, than it has been heretofore. Dr. Briggs, since his arrival, reports another successful case.

SATURDAY, MAY 3D—FOURTH DAY.

DR. W. T. BRIGGS, of Nashville, read a paper on

THE TREATMENT OF EPILEPSY ARISING FROM INJURIES OF THE HEAD, WITH SPECIAL REFERENCE TO USE OF THE TREPHINE.

Reference was made in the introduction to the brilliant results arising from experiments on animals in the elucidation of the essential nature and pathology of epilepsy. Little was known of the disease until, in 1850, Marshall Hall enunciated his theory of the reflex action of the nervous system, and pointed to the medulla as the centre of this reflex system. Since that time various men have given attention to the subject; notably, Brown-Séquard, Schroeder Van der Kolk, Nothnagel, Myers, Kussmaul, Zenner, and Donders, and of them and their works the author gave a careful review. He next spoke of the time usually intervening between the receipt of injury and the development of epilepsy, and the significance of pain and tenderness over old injuries when associated with epilepsy. The following statements were emphasized: That epilepsy is, in the present state of our knowledge, essentially a functional disease; that two factors are necessary in the production of every case of epilepsy, and must *always* be present, viz., increased susceptibility of the reflex centres and a peripheral irritation; that the author had confined his remarks to those cases arising from injuries of the head which demand operative measures; that such injuries may involve the scalp only, or the cranial vault without fracture, but most frequently with fractures resulting in direct pressure or subsequent pressure, by osteophytes growing from the new bone between the fragments; that in case the point of irritation is situated in the scalp, and the attack is clearly referable to it, the excision of the scar, including the irritable fibrillæ of nerves, should be effected; that if the point of irritation is set up by osteo-sclerosis or hyperostoses of the cranial bones, the trephine should be used and the point of irritation removed; and that, if from depressed fracture of the cranial bones, or osteophytic growths from them, the trephine is demanded.

The statistics collected by Billings and Stephen Smith were given, showing 92 American cases in which trephining had been resorted to, of which 63 were cured, 13 ameliorated, 2 not changed, 14 died. From his own practice 30 cases were given, of which 25 were cured, 3 ameliorated, 1 not changed, 1 died, showing that the mortality is not greater than that of other operations of equal magnitude. He indulged the hope that the mortality may be still further reduced, and asserted that the use of the trephine in such cases is as legitimate as is lithotomy for the removal of stone. The treatment after the operation is important, for the increased irritability invariably established continues for a long time, ready to burst forth into active disease from other peripheral irritation.

As guides to the performance of the operation, the following points were given:

1. The operation should be done as early as possible.
2. It should be thorough and complete.
3. It should be carefully and cautiously done.
4. The wound should be dressed after the open method.
5. Careful after-treatment should be instituted to prevent destructive inflammation.

DR. L. A. SAYRE, in opening the discussion, reported a case to which he had applied the trephine, expecting to find an exostosis but, instead, ound a considerable excavation, the bone being much thinner over a circumscribed area than was normal. Through this excavated area he was also so fortunate as to find the line of the original fracture. The patient thus operated upon was permanently cured, so that he went through the war without any return of it, and is now a policeman in New York. In reference to the pathology of this case, the speaker said that he was at a loss to account for the good result that followed the operation, unless the removal of a button of bone had in some way relieved some embarrassment of the circulation.

DR. CAMPBELL remarked that he believed the bad results reported by many as following trephining for epilepsy were due to the fact that the button removed is too small. Instead of a piece an inch in diameter being taken out, a piece double that size, or larger, should be removed.

Dr. Mears called attention to an expedient to which he had resorted. A boy, aged thirteen years, was brought to St. Mary's Hospital, in Philadelphia, to be operated upon for epilepsy following the history of a fall. Fearing that there was a hysterical element in the case, he had the patient closely watched until the true epileptic character was pretty certainly decided. He raised a V-shaped piece of the scalp, then dissected out the somewhat thickened and inflamed tissues underlying, and closed the wound by suture. Prompt union occurred, and permanent cure resulted.

Dr. Roberts inquired whether the author of either of the papers, or any other Fellow of the Association, had ever used the actual cautery for the relief of these cases of superficial irritation. He had used it once with good result, and recommeded it for the certainty with which it would destroy the abnormal irritability of the parts to which it was applied.

Dr. Byrd endorsed the remarks of Dr. Campbell in regard to the propriety of removing a large button of bone, and stated that if he had the opportunity of repeating the operation on the case of insanity which he reported yesterday, he would remove a piece two and a half instead of one and a half inches in diameter. He also reported a case which had been twice operated upon with the trephine at an interval of two years, with only temporary relief. At the end of another two years he came to him requesting a third operation. A large portion of one parietal bone had already been removed, and he decided to try medicine. He gave him a mixture containing the bromide and iodide of potassium, with the result of preventing a return of the affection while he continued to take the remedy.

Dr. Gouley advised going a step further in the use of the trephine, recommending its use in cases of painful cicatrices as soon as there was any complaint of pain or of compression, without waiting for the epilepsy to be developed. In this way, he thought, many cases of epilepsy would be averted. He had made use of this plan a number of times with no bad effects. On the other hand, he had seen the operation made for epileptic seizures without any benefit. A case of this kind was reported.

Dr. Briggs, in concluding, replied that he had never employed the thermo-cautery in operations of the kind referred to. Neither did he favor it as a method. If the irritation were in the scalp alone, he thought the knife could remove the irritable portion about as well as the hot iron, and if the point of irritation were not in the scalp, the hot iron would certainly fail to reach it.

Dr. Basil Norris, U. S. A., then read a paper entitled

EXTIRPATION OF THE ENTIRE TONGUE,

with a tabular statement of one hundred and twenty-six cases, giving the name of the operator, the date of operation, together with the results in each case, and various other remarks. In respect to authorities quoted, the paper was also exhaustive, referring to all the leading English, French, German, Italian, and American writers. An account of the various methods of performing the operation was given, and points of excellence emphasized wherever met. In regard to the advisability of the removal of the entire tongue, the author considers it not only justifiable, but highly commendable to the operator.

Dr. MacLean said that it had been a long time before he would undertake this operation, but that he had performed it in a few cases, and in a great many more had removed a large part of the organ. He spoke further of the cancerous destruction of the tongue in children. He believed that in most cases these were in reality syphilitic, or a cancerous degeneration following a syphilitic disease of the tongue.

Dr. McGraw expressed the belief that these syphilitic ulcerations are very liable to become cancerous. He also reported a case in which he had witnessed the transformation. A man had consulted him in the early part of summer. As there was a clear syphilitic history, he put him on the iodide of potassium. A few months later, he was compelled to split the tongue and remove a half of it. This, however, failed to check the disease, and it continued to grow in the submaxillary glands.

Dr. Campbell reported a case of hypertrophic glossitis in which he removed a larger part of the tongue with almost no hemorrhage.

Dr. Prewitt reported a case in which he had removed the tongue with the infiltrated glands beneath it, splitting the jaw and accomplishing the removal chiefly with the scissors without much difficulty, but he very nearly lost his patient from suffocation by the thick, ropy mucus that accumulated in his throat. To relieve this he had probangs made, and taught his patient to remove the mucus with them. He also employed a flexible stomach-tube to feed his patient. At the expiration of about a week a secondary hemorrhage occurred from the lingual artery just behind a ligature he had placed on it.

Dr. Tiffany stated that he had noticed the uniformity with which the Fellows who reported cases of extirpation of the tongue spoke of the fear of hemorrhage. He had been accustomed, he said, to make operations about the mouth with the patient lying on his abdomen, his shoulders being supported by two assistants and his head by a towel in the hands of a third assistant who stood behind one of the others. In this position, with the head turned toward a side light, any operation could be made with impunity, so far as hemorrhage was concerned, since the blood was carried forward and out of the mouth.

Dr. C. H. Mastin, of Mobile, then read a paper on

PROSTATIC CALCULI, THEIR PROBABLE CAUSES, WITH NOTES OF REMARKABLE CASES.

Renal and vesical calculi, he said, have, from the earliest history of our profession, offered a fertile field for pathological research, and those minute concretions which form within the follicles of the prostate gland have proved especially interesting, since their true cause has, as yet, not been thoroughly understood. These concretions, almost microscopic at first, gradually increase, yet rarely acquire any considerable dimensions, seldom becoming larger than an ordinary pea. Still, they accumulate in considerable numbers, studding the follicles of the gland, or when increasing in size they break down its parenchyma and collect in distinct cysts. They increase in size, doubtless, from a deposition on their surface, and when not escaping from the follicles cause absorption of tissue by direct pressure, and thus come into contact, forming considerable numbers collected together in one or more distinct pouches. Usually

we find several calculi, each seated in a separate duct; these are generally quiescent and give no evidence of their presence; doubtless they frequently escape along the ducts of the prostate into the urethra and the bladder, and are washed out by the urine. Again, these numerous concretions increasing in size may collect together and light up inflammation, cause constitutional disturbance, terminate in abscess with ulceration, and be discharged either through the rectum or perineum. It is possible that, not being discharged, they may become the nucleus of vesical calculi. This, however, the author considered not probable, since it is rare to find vesical calculi having a phosphatic nucleus encrusted with lithates. The generally accepted opinion of the development of these stones by the formation of concentric layers while yet held in the oval vesicles of the prostate was then reviewed. Notice was taken of the fact that the chemical composition of these calculi varies in the various stages of their development, and is at all times widely different from either renal or vesical calculi. Sassaigue gives as the chemical analysis of these stones in one hundred parts, basic phosphate of lime 84.5, carbonate of lime 0.5, animal matter 15.0 parts. The various ways in which this analysis and other points in the history of the formation of the vesical and prostatic calculi contrasted were pointed out. The author then called attention to several cases, remarkable for the large number of stones removed or for other features connected with them. Dr. T. Herbert Barker, he said, had removed, in 1843, from a laborer twenty-six years of age, twenty-nine calculi, aggregating 1681 grains Troy. The mass of these stones, as they were removed adhering together, measured over four inches in length. A similar specimen, but with no history, is catalogued in the collection of Guy's Hospital. Several other cases were referred to, including some which were reported as prostatic, but which upon closer inspection were undoubtedly of renal or vesical origin, and had simply lodged in the prostatic portion of the urethra—termed by the author secondary prostatic calculi.

A case was next reported in which the author had removed, so far as he had been able to ascertain, the first single stone of truly prostatic origin, and the several steps of the operation given. The calculus was also presented to the Association. It resembled very much in size and shape, the normal adult prostate. Its weight was four hundred and thirty grains Troy. A chemical examination of fragments broken off during extraction, was made by Prof. T. G. Wormley, who pronounced them calcium phosphate. A section of the stone had not been made because the author had desired to present it intact.

DR. GOULEY did not believe the occurrence of prostatic calculi by any means so rare as it is generally considered. Nachet, who has had more experience than any other living writer, speaks of prostatic calculi as occurring in nearly every case of enlarged prostate; what we recognize as adenoid prostate and in the soft prostate. The same author says that while the soft prostate frequently contains calculi, the hard prostate is more apt to contain cysts. The speaker further referred to the large number of prostatic stones usually found. One could not cut into one of these soft prostates without experiencing a sensation as of cutting through sand. They are very gritty, but very small. They frequently do not seem to do any harm. Why this is, he did not venture to say. The prostatic secretion is physiological, and so long as it is undisturbed, no harm ensues. If the description of this distinguished French author was correct, the speaker thought we must consider the disease referred to as another affection, inasmuch as these stones destroyed the prostate. In similar cases which had come under his observation, he had considered the stones found in the prostate simply foreign bodies lodged there. They do not occur, at least in cases in which the prostate is enlarged. He believed that, as Dr. Mastin had said, a distinction should be made between stones formed in the follicles of the prostate and those lodging there. He further recognized the great difficulty of making this distinction, and suggested the probability that the stone presented by the essayist, from the fact of its size and its being single, was truly of vesical or renal origin, having received its external coating while lying in the cavity it had formed in the prostate, and that if a section of the stone were made, it would be found to contain a nucleus composed of urates.

Reference was then made to the difficulty frequently experienced, in cases of this kind, when attempting to feel the stone with the sound, and several cases were reported in which he had been able to get the "click" only after persistent and repeated efforts with the aid of anæsthesia. In one case a man had carried one of these stones for twelve years, knowing that something was wrong.

DR. CAMPBELL reported a patient from whom he had removed at one time two hundred and ten stones, at another time, ten years later, fifty-eight stones, which he believed were of prostatic origin. He stated further that, according to his experience, five-sixths of the stones cut out of the bladder have a uric acid nucleus.

DR. GUNN thought that one of the late speakers attempted to put a straight-jacket on the term "prostatic calculi." He said that since it is customary to call all stones taken from the bladder vesical calculi, he saw no reason for not calling all stones taken from the prostate prostatic calculi. A renal calculus lodging in the bladder and receiving concretions there became a vesical calculus; so, he thought, a vesical or renal calculus lodging in the prostatic urethra, and there forming an excavation, should be considered a prostatic calculus.

DR. MASTIN said that inasmuch as Dr. Gouley admitted that stones from the bladder are coated with deposits of the various urates, the ammonio-magnesic phosphates, or combinations of these, but not with pure phosphate of lime—as the chemical examination of this one showed it to be—he must still insist that was purely of prostatic origin.

TELEGRAM TO DR. GROSS.

The following telegram was ordered sent:

"PROF. S. D. GROSS, Philadelphia.

"The American Surgical Association are unwilling to depart until they are able to learn whether their hope for the improvement of your health has been realized."

The following, recommended by the Nominating Committee, were elected

OFFICERS FOR THE ENSUING YEAR:

President.—WILLIAM T. BRIGGS, M.D., of Nashville, Tenn.

Vice-Presidents.—J. C. HUTCHISON, M.D., of Brooklyn, N. Y.; E. H. GREGORY, M.D., of St. Louis, Mo.

Secretary.—J. R. WEIST, M.D., of Richmond, Ind.

Treasurer.—JOHN H. BRINTON, M.D., of Philadelphia.

Recorder.—J. EWING MEARS, M.D., of Philadelphia.

Council.—HENRY F. CAMPBELL, M.D., 1885; HUNTER MCGUIRE, M.D., 1886; P. S. CONNER, M.D., 1887; J. S. BILLINGS, M.D., 1888.

Drs. E. M. Moore and Lewis A. Sayre were appointed

DELEGATES TO THE INTERNATIONAL MEDICAL CONGRESS AND THE BRITISH MEDICAL ASSOCIATION.

Washington was chosen as the place of the next meeting, to be held the last Tuesday in April, 1885, and to continue four days. Dr. Billings was appointed Chairman of the Committee of Arrangements.

DR. T. F. PREWITT, of St. Louis, then read a paper entitled,

TWO CASES OF MALIGNANT DEGENERATION OF ULCERS OF THE LEG; ONE EPITHELIOMATOUS, THE OTHER SARCOMATOUS; WITH THEIR BEARING UPON THE QUESTION OF THE LOCAL ORIGIN OF MALIGNANT GROWTHS.

The first case was that of a hod-carrier, forty-seven years old, who had suffered for twenty years from an ulceration of the leg resulting from repeated injuries. His general health was excellent. At the end of this time the sore presented an irregular cell proliferation on its surface. The granulations were removed, but not examined microscopically. Nearly two years later, however—in February last—he again returned, with a characteristic epitheliomatous bunch of granulations springing from the old sore, and the neighboring glands enlarged. He refused to have an amputation performed, and the tumor was excised. But as soon as granulation commenced, there was evidence of the epitheliomatous growth. Microscopic examination confirmed the diagnosis. The tumor is still growing, the glands remaining in about the original condition. The second case was a woman, sixty-seven years of age, tall and angular, weighing one hundred and fifty pounds. She had received an injury to the right leg fifteen years ago. Ulceration occurred on the inner side of the leg. Ten years ago a similar ulcer formed on the outer side. Two years ago, when first seen by the author, the surface was covered with scant granulations, the margins calloused, and the tissues around somewhat congested. Varicose veins were present in the upper part of the leg. Last October, the patient noticed a bulging of the lower part of the ulcer. A portion of the growth was excised, and pronounced by Dr. F. A. Glasgow probably a sarcoma. The whole tumor being removed later, it was pronounced by the same gentleman a fibro-sarcoma. The author expressed his belief that, had these two individuals never suffered from the ulcerations noted in the paper, they would have never suffered from the malignant diseases to which they became subject later.

After reviewing the arguments for and against the constitutional origin of malignant growths, the essayist drew the following conclusions:

1. All malignant growths are primarily local in origin.

2. While admitting a constitutional tendency to their development in a limited sense, it is in the same sense and no other that it applies to the development of benign tumors, as chondromas, lipomas, papillomas.

3. Long protracted irritation from any cause may lead to vicious cell-action and development of malignant growths, independent of the existence of any diathesis.

4. The infectiousness of cancer is mainly due to histological characteristics favoring dissemination of germs, rather than to any inherent zymotic quality or spermatic influence, as suggested by Creighton.

5. The recurrence of malignant growths long after removal is due, not to a new outburst, as it were, of the original cancerous dyscrasia, but to the slow development of germs thrown off from the original tumor, and remaining in the system, either at the site of the operation or elsewhere.

6. To argue that heredity, recurrence after operation, or infectiousness, one or all, proves a constitutional origin, proves too much, since all these may be alleged of benign tumors.

7. Early removal of suspicious growths, indeed of all neoplasms, as so earnestly urged by our distinguished ex-President, at our last session, gives the best assurance of complete immunity, or postpones longer the return.

DR. D. MACLEAN briefly reported a case in which a malignant disease of the bladder was due, as he believed, solely to a prostatic irritation by calculi, continuing over several years.

DR. RICHARDSON asked what ground there was for considering the epitheliomatous and sarcomatous conditions in these cases secondary, and why the author did not think that they had existed from the first, since we so frequently see these malignant growths lie a long time dormant.

DR. PREWITT replied that he did not believe a malignant growth would lie so dormant for fifteen or twenty years, as in these cases.

DR. HENRY F. CAMPBELL, of Augusta, then gave an extemporaneous abstract of his paper on

ARTIFICIAL RESPIRATION IN THE SITTING POSTURE.

The speaker described how he discovered his method of artificial respiration. It was one morning, when he was acting as prosector, while drawing his subject from the barrel of alcohol, holding him by the arms, that he was horrified to hear the man, who had been dead six months, take a deep snoring inspiration. He released his grasp, and as the body sank into the barrel, he gave a hoarse expiration! The speaker drew the inference that what would bring breath into a man six months dead would surely do so in the living. He had tried it with the most gratifying results in a number of cases since.

DR. DONALD MACLEAN then gave some clinical notes on

COMPOUND GANGLIA OF THE TENDONS OF THE HAND AND FOOT.

After speaking of the frequency of the affection, especially in the hand, and the views generally held in regard to its pathology, the author related briefly his method of treatment by division of the annular ligament. Just how this caused a cure, he could not state, but he believed that it was by relieving the embarrassment of the circulation, with the removal of pressure, so that the peculiar formation constituting the ganglion was absorbed. In reply to Dr. Gunn, the author stated that

he made no attempt to evacuate the sac of the rice-bodies it contained.

DR. W. S. TREMAINE, U. S. A., reported a successful case of

SUPRAPUBIC LITHOTOMY.

After referring to the infrequency of the suprapubic operation for the removal of a vesical calculus, the essayist reported the following case: J. McH., æt. three and a half years, of good family record, but delicate in appearance and small for his age; had never walked. He had suffered intensely since eighteen months old from retention of urine. The water passed drop by drop, and the pain was great, prolapsus of the rectum occurring at times from the violent efforts at micturition. A number of physicians failed to recognize the difficulty, until Drs. McNiel and Davidson, of the Buffalo Medical and Surgical Dispensary, discovered a calculus. The stone could be felt with the sound at the vesical neck, but the instrument could not be introduced into the bladder any distance. With the finger in the rectum the stone gave the impression of being as large as a hen's egg, and it was immovable. It was evident that extraction through the ordinary perineal section would prove impossible, and therefore the high operation was decided upon. An incision two and a half inches long was made in the median line, down through the linea alba. The peritoneum was carefully pushed back, the bladder opened, and the stone with great difficulty removed. The condition of the bladder was bad. A rubber drainage-tube was introduced, and the upper part of the wound closed. Prompt union occurred. The temperature ranged for several days from 101° to 102°, but the child made an excellent recovery.

A photograph of the calculus was exhibited. The stone weighed nine drachms, was two and five-eighths inches in length, and one and one-quarter inch in its largest diameter, being, in the opinion of the essayist, the largest stone ever extracted from a child of that age, with recovery.

In conclusion, the speaker referred to the accidents of lateral lithotomy as enumerated by Gouley, and showed that the suprapubic operation not only eliminated these, but was on the whole much safer and more easy of execution. The statistics, he believes, misrepresent the operation when they show a mortality against it. "It is safer as regards after-consequences, and is *the* method, the natural, safe, direct route to the interior of the bladder when section is necessary, and the burden of proof is on the advocates of perineal section to show wherein there are any advantages by the circuitous, dangerous, dark route." . . .

DR. GOULEY did not favor the operation. He said that with the present instruments for crushing the stone it would be almost never necessary. It would be performed only by operators at a distance from large cities, when they came in contact with large stones that they were unable to remove through the perineal incision, and were not able to get crushing instruments.

DR. GUNN said that while the suprapubic operation will succeed well in skilled hands, like those of the essayist, it was not a sufficiently safe one to be undertaken by the general surgeon.

DR. JOHN B. ROBERTS uttered the prophecy that within ten years the suprapubic operation would be the one in common use. It was the one that would be chosen by the young men in the profession in preference to one that seemed so fraught with difficulties as does perineal section.

DR. DAWSON agreed with the last speaker as to the probability of this operation growing in favor, though he did not expect its adoption to be so rapid. He further stated that in the western States many of the calculi are so hard as to render crushing, or even the use of the drill, out of the question.

DR. BRIGGS reported a case in which he had removed a stone of enormous size from the bladder of a boy nine years old by this method. But as the boy was in a moribund condition, and he had operated only at the earnest entreaty of the parents, only temporary relief was given, the urine continuing suppressed.

DR. JOHN B. ROBERTS, of Philadelphia, then read, in abstract, a paper on

THE LOCALIZATION OF PERINEPHRIC LESIONS BY MEANS OF CLINICO-ANATOMICAL STUDY,

stated that his paper was suggestive, rather than demonstrative or conclusive, and that he hoped the Fellows of the Association would investigate all cases of perinephric disease, which they met, with a view to definite localization. The lesions liable to involve this region, primarily or secondarily, are inflammation, abscess, cancer of the kidney, cystic degeneration, renal calculi, hydronephrosis, etc. The early recognition of the exact seat of such lesions can only arise from study of anatomical relations and clinical histories. The importance of such localizing knowledge will not be gainsaid in these days of nephrotomy, nephrectomy, and kindred operations. As the study of cerebral localization has now advanced beyond the stage of speculative physiology and has become of practical value to the physician and surgeon, so will the study that leads to localization of perinephric lesions become of future value. The symptoms and signs which must guide us in fixing the exact site are those due to extension of inflammation to adjacent structures, and those caused by increase of bulk at the seat of disease. These may be termed the localizing symptoms as discriminated from the inherent symptoms of the lesion itself. Although there are no dividing lines separating the perinephric area into tracts, it is convenient to speak of upper, middle, and lower anterior, and upper, middle, and lower posterior tracts. The speaker then discussed the varying symptoms likely to be produced by lesions in these different tracts, and from the clinical histories of cases reported by himself and others, and from anatomical study, deduced the following conclusions:

A table of symptoms of probable and possible value in localizing perinephritis and perinephric lesions:

All anterior regions: Pain, tenderness, swelling, œdema, pointing, etc., in front and side of abdomen.

All posterior regions: Pain, tenderness, swelling, œdema, pointing, etc., in loin.

Upper tracts: Pleuritic friction, pleural effusion, empyema, expectoration of pus, dyspnœa, suprarenal involvement, solar plexus involvement. If on right side, bilateral œdema of legs, jaundice, fatty stools, persistent vomiting, rapid emaciation, ascites.

Middle tracts: Albuminuria and casts; suprapubic, scrotal, or vulvar pain or anæsthesia; suppression of

urine; uræmia; pus in the urine; œdema of scrotum or varicocele (especially on left side).

Lower tracts: Flexion of hip; pain or anæsthesia of front, inside, or outside of thigh; retraction of testicle; pain at knee; scrotal or vulvar pain or anæsthesia, without accompanying albuminuria; unilateral œdema of legs; abscess or sinus near Poupart's ligament; constipation (if left side); involvement of chyle receptacle (if right side).

The discussion of the paper was postponed from lack of time.

UNSETTLED QUESTIONS IN RELATION TO INJURIES OF THE HEAD

was the subject of a short paper by DR. DAVID PRINCE, of Jacksonville, Illinois. The question chiefly discussed was the propriety of making exploratory incisions in cases of injury of the head in which it is doubtful whether or not the bone is depressed or even broken. In the opinion of the essayist, such incision was not only justifiable, but the duty of the surgeon. In cases of depression, in which the injury can be at once recognized through the opening in the scalp received at the time of injury, it is advised by high authority to elevate the depressed bone at once. When the danger from a simple incision of the scalp is so slight as it is now, with our improved antiseptic measures, should the suspicion of a depressed bone go unverified? Is it not better to investigate, and, if an injury is found, relieve it at once? The chief argument, at least for the innocence of the operation, lies in the power of antiseptics to prevent the occurrence of putrefactive changes in the wound. The speaker expressed his preference for carbolic acid over the newer and, as he believed, less efficient antiseptic agents. He further insisted strongly upon the superiority of the wet dressing as compared with the dry, and expressed in strong terms his distrust of dry dressings of any kind when applied to the scalp. It is impossible, he said, to secure a germ-proof contact between a dry dressing and a surface on which hair is growing as rapidly as it does on the scalp, and pushing up the materials employed. But he believed that if putrefactive changes have once developed in the recesses on either side of the dura mater, they cannot be overtaken by any kind of antiseptics not destructive to the tissues of the patient. To prevent this putrefaction, the author applies the carbolic acid solution every twenty minutes.

The following papers were read by title, and ordered published in the volume of *Transactions*: *Anæsthesia and Plaster-of-Paris Bandage in the Treatment of Sciatic Neuralgia*, by Dr. John A. Comingor, of Indianapolis, and *Practical Views of Neoplasms*, by Dr. E. H. Gregory, of St. Louis.

A paper by Dr. Fenger, on *Cerebral Abscess*, read by title, was ordered published in the *Transactions*.

A COMMITTEE ON NECROLOGY

was appointed, consisting of Drs. J. Ewing Mears, P. S. Conner, and J. S. Billings.

The committee to investigate the

END-RESULTS OF EXCISIONS DURING THE WAR,

are Drs. Conner, Ashhurst, and Norris.

PRESIDENT MOORE expressed briefly his deep appreciation of the meeting just closing, in which he said he had taken the part more of a spectator than of a participator. The papers have been good, he said, the work has been good, and we should all be satisfied with it as a whole.

He called attention to the fact that in the present meeting the Constitution had been entirely laid aside, inasmuch as thirty papers had been read instead of only six, or two each day as therein provided for. He earnestly recommended that in the future this clause of the Constitution be carefully complied with, since it would lead to the presentation of more carefully prepared papers and a more scientific discussion of them. "We should stand upon a higher and higher plane," he said, "until this Association shall rest upon a more lofty basis than it has ever stood upon before."

A vote of thanks was tendered to the President. The President-elect, Dr. Briggs, was then conducted to the chair, and after he had expressed his gratitude to the Association for the distinction conferred upon him, the session was adjourned.

OBITUARY.

SAMUEL D. GROSS, M.D.

ALTHOUGH in a measure prepared for the sad tidings, the medical profession will learn with deep sorrow that Dr. Samuel D. Gross expired on Tuesday afternoon, May 6th, at his residence in this city, after an illness of four weeks. There had been evidences of failing strength during the preceding three months, which finally culminated in derangement of his digestive powers, and in death from exhaustion. The autopsy, which was made by Professor Da Costa, Dr. J. Ewing Mears, and Dr. Orville Horwitz, disclosed marked gastric catarrh, with irregular thickening of the mucous membrane, fatty heart, and a large cyst of the right kidney. The brain weighed forty-eight ounces; its convolutions were numerous and its sulci deep.

The death of this truly great, noble, pure, and unselfish man closes a life of usefulness that was without a rival in the medical profession of this country, a profession that he honored as much as he loved. His loss will be deeply felt both at home and abroad by a large circle of professional and personal friends, and especially by the younger men, to whom he was always glad to render assistance and advice.

Dr. Gross was born near Easton, Northampton County, Pa., on July 8, 1805, and was, therefore, in the seventy-ninth year of his age. He received his early literary and classical education at the Academy at Wilkesbarre, and subsequently at the High School in Lawrenceville, N. J.; studied medicine under the preceptorship of Dr. J. K. Swift, of Easton, and afterwards became an office pupil of the late Professor George McClellan, graduating from the Jefferson Medical College in 1828. Immediately upon receiving the degree of Doctor of Medicine, he settled in Philadelphia, and employed his leisure hours, which are common to the life of every young physician, in close study and in translating from the French and German languages *Boyle and Hollard's General Anatomy*, *Hatin's Manual of Obstetrics*, *Hildebrand on Typhus Fever*, and *Tavernier's Operative Surgery*. But the master-mind which was destined to guide medical thought wherever the science is recognized, was not content to perform the almost mechanical work of translating, and in 1830, two

years after his graduation, he brought out his *Treatise on the Anatomy, Physiology, and Diseases and Injuries of the Bones and Joints*, in which, for the first time, attention was called to the use of adhesive plaster as a means of extension in the treatment of fractures of the lower extremity. In the same year he returned to Easton, where he remained until 1833, when he was made Demonstrator of Anatomy in the Medical College of Ohio. After holding this position for two years, he accepted the Chair of Pathological Anatomy in the Cincinnati Medical College, then newly organized, and delivered the first systematic course of lectures on Morbid Anatomy ever given in the United States. In 1832, before going to the West, Dr. Gross performed a series of experiments on hanging and manual strangulation, the results of which were published in the *Western Journal of Medicine*, and afterward incorporated by Dr. T. Romeyne Beck in his great work on *Medical Jurisprudence*. He also made numerous observations on the temperature of the blood and on the coagulation of that fluid as influenced by various circumstances.

During his residence in Cincinnati, his occupancy of the Chair of Pathological Anatomy enabled him to devote much of his attention to this subject, and in 1839, he brought out his *Elements of Pathological Anatomy*, which passed through two subsequent editions in 1845 and 1857. This was the first systematic treatise on this subject in the English language. After teaching in Cincinnati for four years, he was called to the Chair of Surgery in the University of Louisville, where he remained until 1850, when he was elected to the same Chair in the University of New York. While in Cincinnati and Louisville his pen was not idle. His *Experimental and Critical Inquiry into the Nature and Treatment of Wounds of the Intestines*, appeared in 1843, *Treatise on the Urinary Organs*, in 1851, a third edition being demanded, in 1876, and a *Treatise on Foreign Bodies in the Air-passages*, in 1854.

After remaining in New York for one year he returned to the University of Louisville, at the earnest solicitations of his former colleagues in that school. But a greater place was being prepared for him. In 1856 he was elected to the Chair of Surgery in the Jefferson Medical College, from which the distinguished Mütter had just resigned. This position, offered by his Alma Mater, was accepted, and the remainder of his long and useful life was spent in Philadelphia.

One year, in 1857, after coming to the Jefferson College, the great literary work of his life, his *System of Surgery*, appeared, the sixth edition of which was issued in 1882. His reputation as a teacher and surgeon was already established, and if anything were necessary to increase his national and foreign reputation, his *System of Surgery* at once and completely established it. Being at present the text-book in fully one-half of the medical colleges in America, and the acknowledged standard for surgeons throughout the country, it is scarcely necessary to more than mention it to the American profession. But the appreciation of this encyclopædic work is not confined to this country, as in 1863 it was translated into the Dutch, and, if we do not mistake, into the Russian language.

He was one of the five authors of *A Century of American Medicine*, published in 1876, the chapter on surgery being from his pen. He was one of the founders and editor-in chief of the *North American Medico-Chirurgical Review*, the publication of which was stopped by the War of the Rebellion, after an existence of five years. He was President of the American Medical Association in 1868, and of the Centennial International Medical Congress in 1876; was founder and first President of the Pathological Society of Philadelphia, of the Philadelphia Academy of Surgery, and of the American Surgical Association. He was a Professor of Surgery for forty-two years, during which period he dwelt with great emphasis on the guiding principles of that branch of medicine, and was the first to suggest or perform the operation of wiring the dislocated clavicle to the sternum or acromion process, the suturing of divided nerves and tendons, amputation high up in senile gangrene, a modification of Pirogoff's amputation, an operation for neuralgia of the jaw in old persons, deep stitches in wounds of the abdomen, and a direct operation for hernia by suturing the pillars of the ring. He was also the first to describe prostatorrhœa, and was the inventor of numerous instruments.

No American physician ever had so many or so great honors from celebrated institutions of learning as Dr. Gross. In 1872, Oxford conferred upon him the degree of D.C.L.; in 1861, the Jefferson College, of Cannonsburgh, the degree of LL.D.; Cambridge her LL.D., in 1880, and the University of Edinburgh and the University of Pennsylvania conferred the same degree in April and May, 1884. He was a Member or Fellow of a large number of medical societies and organizations both American and foreign, including the American Philosophical Society, the Imperial Medical Society of Vienna, the British Medical Association, the Royal Medico-Chirurgical Society of London, the Clinical Society of London, and the Pathological Society of London.

In addition to the works already mentioned, Dr. Gross was well known as a voluminous, clear, and entertaining writer for the medical press. His addresses, introductory and valedictory and his biographical memoirs of various medical men are numerous, including, among the last, those of Ambrose Paré, Ephraim McDowell, Daniel Drake, John Syng Dorsey, J. Cobb, Charles Short, Valentine Mott, and Robley Dunglison. While in Louisville he prepared an exhaustive report on Kentucky surgery, which was published in the *Transactions* of the Medical Society of that State, and in which he first established the fact that Dr. Ephraim McDowell was justly entitled to the honor of being the father of ovariotomy.

In 1882, after having taught surgery for forty-two years, he relinquished his laborious duties as an active teacher, and to the regret of his colleagues, the trustees of the institution, and the whole profession, he resigned his Chair in the Jefferson Medical College. As a teacher, a lecturer, and an operator, Dr. Gross was greatly respected and admired by his classes. He was an untiring student, systematic and economical of his time, and while punctually fulfilling his engagements as professor and practitioner, he was enabled to keep himself thoroughly informed in medical and general literature. His extensive knowledge of disease, added to a ready facility in diagnosis, enabled him to grasp at a glance the salient features of a case. He was never satisfied unless his work was thoroughly

done, and felt that in every case he had a triple duty to perform: first, and above all, to his patient; secondly, to his pupils; and, lastly, to himself. No surgeon was ever more alive to the responsibilities of his office, or more determined to perform them with an eye single to the best interests of all concerned. He was always a warm advocate of a higher grade of education, and a more thorough course of instruction for the student of medicine. Whether as surgeon, author, or lecturer, the stamp of his individuality has been indelibly impressed upon the history of science in America. He was never content simply to keep pace with the stride of scientific research, but has often been the pioneer to open up unexplored regions. With him, science and humanity have gone hand in hand, and, as a result, the technical and general literature of the century has been enriched by his works, and humanity made happier by the greatness of his heart.

Among his last contributions to his profession may be mentioned his paper on *The Value of Early Operations in Morbid Growths*, read before the American Surgical Association, in 1883; *Remarks on the Importance of Trained Nurses*, which appeared in The Medical News of September 15, 1883; a paper on *Wounds of the Intestines*, read before the American Surgical Association by his former pupil, Prof. Richardson, of New Orleans, April 30th; and one on *Lacerations of the Female Sexual Organs*, read, on May 8th, by Dr. Busey, before the American Medical Association. These last papers bear the stamp of that patient and untiring "research in the past, which lend to the learning of the present its highest value." Truly it may be said of him that he died in harness; and though the threescore years and ten had almost gone on to fourscore, his mind still retained the vigor with which it had worked for over half a century.

EDINBURGH.

(*From our Travelling Correspondent.*)

The Tercentenary Festival of the University of Edinburgh, which closed last night with a general illumination of the city, has been admirably managed throughout, and has made this place temporarily the centre of interest for the scientific and literary world. As remarked by Sir Alexander Grant, we could almost say now of the University of Edinburgh what was said of Portia:

> "Nor is the wide world ignorant of her worth,
> For the four winds blow in from every coast,
> Renowned suitors."

But while in the crowd of distinguished guests, delegates from other universities and from learned societies, and recipients of the honorary degrees conferred, all faculties were represented, and divinity, law, literature, science, poetry, and art each received due honor, it is no disparagement to all these to say that medicine was preëminent over all of them in the number and character of its representatives; and it is fitting and proper that this should be the case. During the last half of the last century, the medical school of the University of Edinburgh was the leading medical school of the world, and drew students from all civilized countries. To a considerable extent, this is still the case, and, with its fifteen hundred medical students, it is, if not the largest, as claimed by Prof. Fraser, certainly one of the three largest medical schools in existence.

At the luncheon given by the Medical Faculty in its new buildings, the scene, and the names of the speakers, reminded one vividly of the London International Congress of 1881, and the same may be said of the impressive graduation ceremony and of the banquet.

The new buildings of the Medical Department of the University attracted much attention on the part of visitors, and are well worthy of careful examination by all who are interested in medical education, since they may be taken as embodying in concrete form the latest views of experts in this matter. They are built of the gray stone of which all important buildings in the city are constructed, and are arranged around a large quadrangle, the entrance to which is through a fine arch which is a prominent feature of the principal front.

In these buildings the nine departments of anatomy, surgery, practice of physic, physiology, pathology, midwifery, chemistry, materia medica, and medical jurisprudence, are accommodated, each having its own amphitheatre or lecture-room, and its own laboratory or practical rooms. Special facilities are provided in each department for experimental work and original investigations by the professor and his assistants, the laboratories are well fitted up, and the whole structure is thoroughly fireproof. The new infirmary close by gives the means of clinical instruction, and when the size of the classes is considered—including about 1500 medical students—it is difficult to suggest improvement in the plans for their accomodation. It should be remembered in this connection, however, that a large number of these students receive a very considerable part of their instruction not in the University, but in the extra-mural school, which is an extremely important appendage to it.

The greatest and most imposing gathering of the Tercentenary was that for the reception of delegates and the conferring of honorary degrees, which took place in the great Synod Hall on Thursday, April 17th. Probably there has never before been gathered under one roof such a truly cosmopolitan assemblage of acknowledged leaders in philosophy, literature, science, and art. Every European State, except Spain, Turkey, and Greece, was represented, and delegates from both North and South America, from India, Japan, Australia, and the Cape of Good Hope were also present. The delegates from European universities and learned societies presented a quaint and attractive sight in their robes and caps, many of which were of colors and fashions adopted centuries ago. Among these were especially conspicuous the flowing green robe and high black velvet collar, worn by Professor Pettenkofer, the bright crimson of Professor Ollier, of Lyons, and the gorgeous yellow silk robe of Professor Mézières, of Paris. After the presentation of the delegates to the Chancellor, the latter proceeded to confer the honorary degrees awarded by the University, including sixteen D.D.'s and one hundred and twenty-two LL.D.'s. Among the recipients of the latter were the following medical men, viz.: George W. Balfour, President of the Royal College of Physicians, Edinburgh; Fordyce Barker, of New York; John S. Billings,

U. S. Army; Sir William Bowman; John S. Bristowe; Sir Andrew Clark; Surgeon-General Thomas Crawford; Professor John E. Erichsen; Professor S. D. Gross; Sir William Gull; Professor H. von Helmholtz; Dr. J. Henle; Dr. Joseph Hyrtl; Dr. Haldane; Sir William Jenner; Thomas Keith; John Marshall, President of the Royal College of Surgeons, London; Dr. H. Maudsley; Dr. H. Gueneau de Mussy; Professor Ollier; Sir James Paget; Professor von Pettenkofer; Dr. Priestly; Sir J. W. Reid, Director-General Medical Department, Royal Navy; Professor Saxtorph, of Copenhagen; Professor Schmiedeberg, of Strassburg; Dr. E. H. Sieveking; Dr. John Smith; Professor B. J. Stokvis, of Amsterdam; Professor Virchow; Dr. P. H. Watson, and Dr. Samuel Wilks.

Among the non-medical men who received the honorary degree of Doctor of Laws, the most conspicuous were: Lieutenant-General Alison, Prof. Cayley, Sir Samuel Ferguson, Mr. Flower, Prof. Franckland, Mr. Froude, Mr. A. Geikie, Prof. Haeckel, Prof. Jowett, Prof. de Laveleye, Sir Frederic Leighton, Baron de Lesseps, Hon. James Russell Lowell, Sir John Lubbock, Sir Henry J. S. Maine, Prof. Mézières, Prof. Pasteur, Count Saffi, Prof. Seely, Prof. Sidgwick, Sir James Stephen, Robert Browning, and Alfred Tennyson.

But if the sight of all these distinguished men was interesting and impressive, scarcely less so was the view which they had on the last day of the festival of some two thousand students gathered in the body of the same great hall, and welcoming with voices, sticks, and waving of hats their favorites among the guests, or the glimpse of the same students obtained by those who saw their torchlight procession, and to many of whom, no doubt, it gave rise to the thought put into words by Mr. Lowell—that it was a coming from the darkness to go into the darkness, yet keeping up the flame.

The great peculiarity of the Edinburgh University is that it was founded and has been maintained by the people, and not by church or king. It has, in Mr. Lowell's words, "gone near to the life of the nation," and it has been a part of the life of the city; it has been "our tounis collidge." And the crowning fame of the University has been, and now is, its medical school, with which the names of Monro, Cullen, Gregory, Bell, Alison, Syme, Christison, Simpson, Lister, Turner, and a long list of others well known in medical literature are indissolubly connected.

American physicians will heartily join in the sentiments expressed by Sir James Paget in proposing a toast to "Prosperity to the Medical School of the University of Edinburgh." He referred to the fact that its career has illustrated the value of rivalry, and that in the work of life an honest and earnest rival is often better than a cautious friend, and wished for it more pupils, more wealth, more museums filled with the treasures of science, a more abundant power of spreading knowledge, and more power in turning knowledge to the utility of men in the remedy of disease. This is the Alma Mater of American medical schools, which have in the main adopted its organization of chairs and methods of management, and which should bid it God-speed in the work which yet remains before it.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—At a meeting of the College of Physicians, held on Wednesday evening, May 7, Dr. J. M. DaCosta was elected President, vice Dr. Samuel Lewis, resigned.

UNIVERSITY OF PENNSYLVANIA.—At the annual commencement of the University, held on May 1st, the degree of M.D. was conferred on one hundred and one candidates; and Dr. T. G. Wormley delivered the Valedictory Address. On behalf of the Graduating Class, a full-length portrait of Prof. Alfred Stillé was presented to the University.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending April 26, 1884, indicate that remittent fever has considerably increased, that diarrhœa, dysentery, measles, and whooping-cough have increased, and that pneumonia, scarlet fever, cerebro-spinal meningitis, and inflammation of the kidney have decreased in area of prevalence.

Including reports by regular observers and others, diphtheria was reported present during the week ending April 26, and since, at four places, scarlet fever at twelve places, and measles at eight places.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 29 TO MAY 5, 1884.

HEGER, ANTHONY, *Major and Surgeon.*—From Department of Texas to Department of the East.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

HAPPORSETT, J. C. G., *Major and Surgeon.*—From Department of Texas to Department of the East.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

BENTLEY, EDWIN, *Major and Surgeon.*—From Department of the East to Department of Texas.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

MIDDLETON, PASSMORE, *Captain and Assistant Surgeon.*—From Department of Texas to Department of Missouri.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

KOERPER, E. A., *Captain and Assistant Surgeon.*—From Department of the East to Department of Dakota.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

DICKSON, J. M., *Captain and Assistant Surgeon.*—From Department of the East to Department of California.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

GIRARD, A. C., *Captain and Assistant Surgeon.*—From Department of Dakota to Department of Missouri.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

GIRARD, J. B., *Captain and Assistant Surgeon.*—From Department of Arizona to Department of the East.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

HALL, J. D., *Captain and Assistant Surgeon.*—From Department of Dakota to Department of the Columbia.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

HALL, WM. R., *Captain and Assistant Surgeon.*—From Department of Missouri to Department of Texas.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

CUNINGHAM, T. A., *Captain and Assistant Surgeon.*—From Department of the East to Department of Missouri.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

MCCREERY, GEORGE, *First Lieutenant and Assistant Surgeon.*—From Department of Arizona to Department of Dakota.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

COCHRAN, J. J., *First Lieutenant and Assistant Surgeon.*—From Department of Missouri to Department of Arizona.—*Par. 2, S. O. 101, A. G. O.*, May 1, 1884.

SCHUFELDT, ROBERT W., *Captain and Assistant Surgeon.*—Relieved from temporary duty in Surgeon General's Office, and ordered to report to Lieutenant-Colonel Basil Norris, Surgeon, U. S. A., Attending Surgeon, Washington, D. C., for temporary duty in his office.—*Par. 6, S. O. 100, A. G. O.*, April 30, 1884.

PHILLIPS, JOHN L., *First Lieutenant and Assistant Surgeon* (Fort Warren, Mass.).—Ordered to report for temporary duty to the Commanding Officer at Fort Preble, Me.—*Par. 1, S. O. 51, Headquarters of Department of the East*, April 25, 1884.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLIV. SATURDAY, MAY 17, 1884. NO. 20

AMERICAN MEDICAL ASSOCIATION.

THIRTY-FIFTH ANNUAL MEETING, WASHINGTON, 1884.

THE ADDRESS IN SURGERY.

Delivered May 8, 1884.

BY CHARLES T. PARKES, M.D.,

PROFESSOR OF ANATOMY IN RUSH MEDICAL COLLEGE, CHICAGO.

GENTLEMEN: The subject-matter of the remarks to be presented this morning was suggested to me by an article published in the *British Medical Journal*, in 1882, from the pen of "that good man among men, and great man among doctors"—J. Marion Sims. The article in question was an appeal for operative interference in penetrating gunshot wounds of the abdomen, in lieu of the "expectant treatment" so universally accepted and adopted by the profession, and which, in a few seemingly well-authenticated instances, has led to recovery. The appeal was uttered in behalf of the vast majority on the side of fatality attending these cases, and was based upon the deductions to be drawn from the recoveries, following operations for diseases affecting the viscera of the abdomen and pelvis, during which the most terrible injuries have been inflicted upon the contents of these cavities—the peritoneum exposed for hours, as well as brought in contact with all kinds of foreign and usually irritating substances.

It is scarcely necessary for me to affirm in your presence the fact that, with few exceptions, the older writers and surgeons advocate the "expectant treatment" in the management of these injuries, while the younger writers and surgeons favor operations, pinning their faith upon the wonderfully favorable results attending the practice of Listerism, the purest of antiseptic surgical methods.

During the past few months I have instituted and carried out, with the valuable assistance of Mr. J. McDill, and Drs. Anthony, Freer, and Bolles, a series of experiments for the purpose of ascertaining the results to be obtained by immediate operations after these wounds; with the hope that the relation of the attending circumstances and events would be interesting as well as useful, by adding to the data now in our possession other data from which may be determined more intelligently the course of action to be adopted when these cases come under our charge for treatment.

No attempt will be made to review the great question of penetrating gunshot wounds of the abdomen, which would lead me beyond the scope of the paper. Nothing but a fair recital of the history of the experiments, with some application of the conclusions to be drawn therefrom, will be undertaken. With this intent in view, there will be presented to you the accompanying phenomena, the manner of treatment, and results of thirty-seven intentional gunshot wounds of the abdomen, confining my attention entirely to my own observations and exhibiting to you such specimens as I have been able to preserve, taken from the animals, both of those which died and of those which were sacrificed, after recovery, to obtain the specimen. Experiments of like nature have been made upon animals by very many surgeons previous to the application of their convictions of the necessity of certain procedures to relieve disease or the effects of injury in the human body. No preparation of the animals selected for experiment was made, either as to choice of physical condition or surrounding circumstances, except that they were anæsthetized previous to being hurt. The wounds were produced by the ordinary Smith and Wesson revolver of 22, 32, 38, and 44 calibre, and by the 22 calibre rifle. The shots were given at short range, so the damage done by the bullet fairly represents the injury met with, either in military or civil practice, as the results of shots from the firearms now in use. At first, no attempt was made to give a definite direction to the course of the bullet other than that it should perforate the abdominal cavity. The results soon confirmed the fact so well known, that the larger number of patients suffering from such wounds never come into the hands of the surgeon, their injuries proving rapidly fatal.

This ending, we can readily understand, must be a common one when we bear in mind the construction and nature of the viscera contained in the cavity, especially their great vascularity, having vessels of immense size supplying them with and carrying away from them the blood necessary for their nutrition and the performance of their special functions; not to mention the main systemic artery and vein coursing through the cavity in a position rendering them readily liable to perforation, death following speedily.

It was also soon ascertained that a severe perforating and lacerated bullet wound of the viscera, such as of the kidneys, of the spleen, and of the pancreas, could not apparently be treated successfully in any other way than by an absolute removal of the injured organ, and notwithstanding the reported successful removal of almost every important organ of the abdomen by one surgeon or another, the conclusion was reached that some of these organs must be left in situ, in order that the functions of life may be carried on. Hence we were compelled to exert such control over the course of the missile as to have it produce a wound of the nature of those likely to come, and actually coming, under the care of the surgeon. So that the injuries became those confined to perforations and injury of the intestinal tube, with occasionally the injury of some of the larger special organs. It will not be amiss to recall to your minds, very briefly, some of the triumphs of abdominal surgery, and more especially to impress the fact that shot wounds of the cavity and contents present many questions of prime importance which are not met with in, and do not complicate, ordinary operations for disease or injury with any free external wound. The removal of the spleen for acute wounds nearly always results in recovery; so also one kidney has been removed successfully, either for disease or injury, often

enough to place the operation of nephrectomy among the list of justifiable undertakings. Again, wounds of the intestinal tube of all degrees of severity, up to complete division by the resection of portions of the entire calibre thereof, have been successfully treated by surgeons, as is proved by the experimental researches of Dr. Traverse, the eminent Prof. S. D. Gross, Dr. Bell, and others, and confirmed by the experience of many surgeons during operations upon the human being for diseases of these cavities. Still, in each of the examples mentioned, the circumstances were entirely different from what is found present in perforating gunshot wounds of the abdomen. In the former, the peritoneal cavity was clear of blood and other extraneous substances; the prevention of their entrance entirely under the control of the operator. In the latter, blood in large amounts was always found present, and the peritoneum was smeared with the contents of the intestinal tube, necessitating prolonged efforts to secure a cavity clear of all hurtful substances. Of necessity, the latter cases would be least likely to escape the probabilities and dangers of subsequent inflammation of the serous membrane.

Primary resection of portions of the intestinal tube, or entire removal of separate organs, are operations comparatively easy of performance, and are not necessarily attended with any damage to or exposure of any other portions of the abdominal cavity, outside of the immediate proximity of the site of the operation. Extravasation and hemorrhage should be entirely prevented and controlled; and the peritoneal sac can be maintained perfectly clean during the time of, and after, all the procedures required by the operation. After gunshot wounds, besides the resection or removal of any special organ required, there is great shock, and prolonged manipulation is necessary to obtain a proper cleanliness.

The recital in detail of each experiment would be tiresome and occupy too much time, so that your attention will be called only to the more important facts and circumstances determined by them. There will be published with the paper a somewhat extended account of each experiment, from which individual inferences may be drawn.

First comes the question of hemorrhage and damage to bloodvessels, as this is primarily the most common and certain cause of death, and demands the surgeon's first attention. In its excessive amount, occurring rapidly and suddenly, is to be found the explanation of the cases which are immediately fatal. This result will surely happen when the largest arterial trunks are severed by the bullet; further, its copiousness and persistency of flow, even when none but very small bloodvessels are divided, involve a matter of serious concern, if not a fatal issue, either from the amount of blood lost, or in predisposing to septic processes from blood decomposition. There is a remarkable persistency in the flow of blood following the severance of vessels in the abdominal cavity, perhaps dependent upon the laxity of the tissues through which these vessels course, the absence of pressure from surrounding soft parts, and the lack of the peculiar influence of the atmosphere, either from its weight or clot-producing power.

When the abdomen is opened immediately after the transit of a bullet, its cavity is found to contain a large amount of blood, the quantity, of course, being in proportion to the size of the vessels wounded, but always a disproportionately large amount, no matter what their calibre; further, the flow is still going on from vessels of all size. There seems to be slight disposition to the formation of an obstructive clot in the mouths of the smaller ones, and slow retraction or contraction of the walls of the larger. Bleeding stops only when the heart ceases to beat in a faint from excessive loss, or when the amount of blood is so large that by its bulk, and weight, and distention of the abdominal walls, it makes pressure sufficient to occlude the open vessels.

The conditions are very quickly altered after air is admitted through the abdominal section. Clots rapidly seal up the smallest vessel; the smaller arteries spurt less forcibly and soon cease beating; the larger ones contract and retract, just as occurs in the wounds of soft parts in other regions of the body. This is in accordance with and corroborative of the experience in hemorrhages occurring in abdominal surgery in the human being. Few of us have failed to see cases like this: A patient dies suddenly, with all the symptoms of acute prostrating hemorrhage. Post-mortem examination shows the abdominal cavity filled with blood. The blood is carefully cleared away in the search for the source whence it came; and when this is found, it is a matter of astonishment that such a vast amount of blood could come from so small a vessel. Perhaps it is a small vein of the ovarian venous plexus, or a minute vessel in the thin-walled sac of an extrauterine fœtation, or the partially closed vessels in the shrunken stump of a recently removed ovarian or other tumor, or some recently divided adhesions—all of them vessels which, in any other part of the body, would be no item of concern to the surgeon, or need any of his special care to prevent bleeding from them.

The lesson taught by these facts is of imperative importance in all operations upon these cavities; and, even if mastered, loses nothing by reiteration. Excessive hemorrhage being certainly the principal cause of speedy death in severe gunshot wounds in this region of the body, where evidences of its presence are plainly exhibited there can be no hope whatever of saving the lives of any of the wounded except by immediate abdominal section. This alone, by admitting air quickly, staunches the fast flowing current, and gives time for the application of the ordinary rules of surgery for the prevention of hemorrhage. In order to be safe from subsequent trouble, every divided bloodvessel must receive the surgeon's attention, occluding clots must be thoroughly sponged away, and in their stead must be placed the ligature or the sear of the actual cautery. If left without this restraint and the abdominal opening be closed, the same conditions are restored as existed previous to the section; and, as reaction comes on, bleeding will surely recur, and in large amount—leading to death from this cause alone, or furnishing a frequent source of septicæmia. This fact, again, is corroborative of the experience of ovariotomists, the most successful being those who take the greatest pains to staunch all bleeding before closing the abdomen.

Following a resection of three or four inches of bowel and a ligation of two large mesenteric arteries wounded by the bullet, there occurred a mortification of several inches of the entire intestine above the site of resection.

The mortified part corresponded with the distribution of the arteries wounded and ligated. This, assuredly, was an important fact to know, if at all likely to occur as the result of wounds of these arterial branches; even its accidental occurrence is a circumstance to be remembered. Its occurrence would surely add largely to the gravity of the cases in which it happened, probably necessitating a resection of a portion of the intestine corresponding to the area of distribution of the wounded vessel. The great freedom of anastomosis between the mesenteric arteries rather argues against their wounds being followed by any such hazardous result; still, the case recorded above required explanation. Two experiments were performed in order to determine whether destruction of the arteries alone was sufficient to lead to such mortification. Both demonstrated that a closure of two or three of the largest subdivisions of the main mesenteric vessel was not in itself sufficient to produce death of the portion of intestine supplied by them.

The complication of a complete resection of the bowel, with a ligation of two or more vessels, is the only explanation to be given of the case in which mortification occurred. The experiments prove that such result does not follow simple closure of the vessels by ligation.

The second item to be considered refers to the course of the bullet, and the character of the damage done by it. Nothing can possibly be more uncertain and erratic than the track of the missile through the body. A contracting muscular fibre, an edge of fascia, the elasticity of the skin, a surface of bone, or a distended knuckle of intestine, each and all of these at times present obstruction sufficient to divert it from the direct line of its flight. It is certainly astonishing what very extensive and severe lacerations of the intestine are produced by so small a bullet as one of calbre No. 22 (Fig. 1), the

Fig. 1.

entire circumference of the bowel at some points being mangled beyond recognition. Again, it is equally surprising how minute are the perforations made by the large No. 44. As a rule, the larger the calibre of the bullet the larger the wound.

An estimate of the direction of transit, based upon the points of entrance and exit, is purely conjectural, and furnishes no standard whatever by which we may judge of any supposed injury to any organs known to lie in such course. In one experiment the bullet made four openings through the abdominal walls, and did no damage other than contusion of two knuckles of the small intestine, and gouging the serous membrane. The animal had a remarkably deep furrow along the course of the "linea alba." The bullet entered the right side of the abdomen obliquely, two inches from the midline, perforated its walls, and, coursing to the left, furrowed the peritoneum in its passage, and was evidently deflected outwards immediately before reaching the linea alba, by a knuckle of intestine which it contused slightly. Here it made its first exit through the walls, passed to the left side of the midline, again perforated the abdominal walls, and, furrowing the peritoneum upon the left side, finally made its second exit through the abdominal walls three inches to the left of the linea alba. Near its place of final exit a second knuckle of intestine was found badly contused. The contusion was so severe and extensive that it was thought best to resect a length of one inch. The animal recovered.

In a second instance the bullet entered the cavity about two inches to the right of the linea alba, on a line with the umbilicus, with a direction upwards and to the left side. It made its exit nine inches to the left of the midline, and just at the lower edge of the last rib. On opening the abdomen the stomach was found greatly distended, entirely concealing the other viscera from view, and presented two large perforations in its walls about two inches apart, from which some blood, mucus, and food were found running into the peritoneal sac. The wound to the right, in the stomach walls, was the smaller and situated directly opposite the entrance perforation in the abdominal wall, having the same direction. The wound to the left in the stomach walls (two inches to the left) was the larger, very ragged, and had evidently been made by the bullet deflected forward at its first entrance into the stomach. After leaving the stomach the bullet impinged upon the inside of the abdominal walls just to the left of the midline, and then, instead of perforating them at that point, was again deflected upwards and to the left, merely furrowing the peritoneum along the remainder of its course to the point of exit mentioned. The wounds of the stomach were inverted, as it were, into the cavity of that organ, by bringing its peritoneal surfaces surrounding the wounds in contact with each other by means of the continued catgut suture. The abdomen was carefully cleansed of blood, etc., and the wounds in the walls closed in the ordinary way. The animal speedily recovered from the injury without any uncomfortable symptoms. During recovery from the effects of the ether, the animal vomited considerable quantities of blood, giving an additional evidence of the perforation of the stomach.

There were two cases in which the bullets perforated the abdominal walls, and in their transit did no injuries to the viscera, and in which the points of entrance were five and six inches apart. In each instance the only damage done was a furrowing and laceration of the peritoneum along their entire courses, the blood from the track of injury falling into the abdominal cavity. In one experiment the bullet failed to penetrate the abdominal walls, and was subsequently dissected from between the muscles. On opening the cavity quite a rent was found in the spleen, opposite to the seat of

the external bullet wound, from which blood was freely flowing. There was neither abrasion nor perforation of the peritoneum. This case may suggest the probable cause of death in some cases from non-perforating wounds. The laceration was evidently caused by concussion alone.

Other instances might be cited to illustrate the exceedingly great uncertainty as to the course taken by the bullet, and as to the organs probably impaired. They would also confirm the possibility of perforations of the walls without accompanying injury to the contents of the abdomen. Still, no instance was shown of failure to produce a wound thereof when the bullet's course lay among the intestines. Their safety followed deviation by glancing.

The wounds of the intestine may be many in number and situated very near to each other (Fig. 2), so that

Fig. 2.

one resection, including all the openings, will constitute the only operation that furnishes relief.

Again, the openings may be few in number and widely removed from each other; and if each wound is large, and the damage to the tube extensive, such as is usually produced by a 32, 38, or 44 calibre bullet, three or four resections are necessary. The latter are the most difficult cases to manage and most fatal in their results. The position of the point of entrance and exit of the bullet in the intestine is subject to immense variety even in simple cases. It may involve only the top of a knuckle of intestine, merely opening the cavity thereof. The points may be so near each other that only a half inch or less of intestinal wall separates them from each other. The bullet may merely cut off the mesenteric junction opening into the cavity more or less freely. The intestine is often perforated transversely near the middle, or longitudinally; in the latter case, the bullet entering at one point, courses along in the cavity of the tube for some inches and then makes its exit.

All of these varieties depend upon the situation of the intestinal folds, with reference to each other, at the time of the transit of the bullet. One case showed ten complete perforations in eighteen inches of length of the ileum.

Extravasation of the contents of the tube was present in every instance in which there existed the slightest degree of perforation. The contents were forced out into the peritoneal cavity or on to the surface of the intestines, if the wound was large, by the bullet itself and the normal tonic contractions of the bowels, and, if small, perhaps by the latter alone. This facility of extravasation agrees with my experience in wounds of the intestine in the human being. I have personal knowledge of two instances in which the medium sized aspirator needle was employed to relieve tympanitic distention of the tube with success, so far as getting rid of the gas was concerned, and giving great temporary comfort to the patient. Death ensued from the disease. Post-mortem examination in each case demonstrated the presence of fecal extravasation at the seat of the needle puncture. It would not be an arduous task to collate instances of this accident, in the practice of others, where this plan has been adopted. It is difficult to understand how any other result could follow a perforation, if there be contents at the seat of the puncture, when we remember how strong and constant is the action of the circular muscular fibre. It is stated that the protrusion or eversion of the mucous coat, which ensues very rapidly after complete division of the walls, acts as an immediate stopper to wounds of small size, say one-eighth of an inch in diameter. This may be true in incised wounds, but it was not shown to exist in a single one of the several hundred perforations coming under my inspection as made by the bullet. The latter tears away and lacerates the parts through which it passes, and perhaps paralyzes the muscular fibre in its immediate neighborhood, but, whatever the cause, there was no instance in which the eversion of the mucous membrane was sufficient to prevent extravasation. Recognizing the very deleterious influence of this material upon the peritoneal membrane, this fact of the great certainty of extravasation adds another point to the argument in favor of abdominal section in these cases, as furnishing the only means by which this source of trouble can be absolutely eliminated. As part of the extravasated material from the wounds of the intestine, it was an exceedingly common thing to find intestinal worms of all kinds and in large numbers, protruding from the rents or free in the serous cavity.

In the treatment adopted during these experimentations, it was found necessary to make an extensive external incision, freely exposing the abdominal cavity, in order that all the viscera might be thoroughly and carefully examined, and every wound brought within reach. In a majority of instances the median line gave space enough. In two, the bleeding vessels could not be reached without a lateral prolongation towards the flanks.

There was no reason to suppose that the extent of the incision added very much, if at all, to the gravity of the operation. After opening the abdomen, the intestines were all turned out, critically examined for perforation or contusion, the situation of these fixed, and the hemorrhage therefrom controlled by means of the snap forceps; after which, wounds of special organs were sought for. If the substance of the spleen or the kidney was found perforated, the organ was immediately removed after ligating its bloodvessels, the stump being

returned to the abdomen. If slight lacerations only at some point on the surface had been produced, these were closed by bringing peritoneal surfaces of the organ over the wound by means of the continued suture.

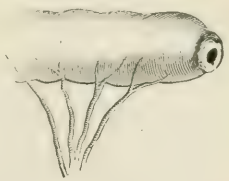
The peritoneal sac was then carefully and thoroughly cleared of blood and other extraneous substances by repeated sponging or irrigation. The intestines, which during this process had been protected by being enveloped in towels wrung out of warm water, were now cleanly sponged, while all unwounded portions were returned to the abdomen.

It seems to be of little consequence whether or not the intestines be returned to the cavity in any definite order—in fact, it is doubtful whether they are ever returned precisely to the same positions they originally occupied before being disarranged during the operation. Still, some care must be used in order to avoid the accident which happened in one experiment. After the divided ends of the intestine had been united, it was found that during the manipulation one of the ends had in some way been passed through an opening in the divided mesentery, so as to produce a figure-of-eight convolution in the tube. It was left in this shape. The animal recovered, and I have the specimen with me to demonstrate the perfectness and security of the union in the intestine at the place of reunion. The animal was sacrified, to secure the specimen, six weeks after the operation. The abdominal cavity was quite free from evidences of inflammation, except where those misplaced folds lay in contact with each other; at this point, slight peritoneal adhesion had formed between them.

Where several wounds occurred rather close together, severe enough to destroy a considerable portion of the integrity of the bowel, one resection was made to include all of them, even when the length of intestine removed measured ten inches or more. Where the points of injury were widely separated from each other, and extensive damage done at each point, several resections, of a length of the tube, just sufficient to include the injured portions, were made. In the former case, in which several inches or more of the tube were taken away, the mesentery was ligated as close as practicable to the intestine (Fig. 3), in sections corresponding to the number of bloodvessels going through it to the resected portions. The mesentery was then divided close to the intestinal wall. After this, the tube itself was separated and the wounded portion removed. One artery always needing ligation was found in the divided ends, at the point of junction of the mesentery with the intestine. Or a triangular section of mesentery removed with the point of the triangle away from the bowel. Before the final division of the intestine, its contents were pushed back out of the way, and compression exercised upon its walls by a pair of forceps or a temporary ligature, in order to prevent extravasation of its contents through the divided ends. The mark of constriction made by the forceps or ligature used to close the lumen of the bowel was to be plainly seen several days after the operation. The safest compression can be made by an assistant's fingers. Results soon demonstrated the paramount necessity of carefully selecting the place for final division of the intestine, in order to avoid sloughing of the edges approximating together, the results being best in those cases in which the division was made close to the point at which any given mesenteric artery approached nearest to the intestine, as compared with those in which the cut was made in the intervals between any two branches of these vessels, and this was seemingly dependent on the better supply of blood belonging to the former cases. Immediately after division of the intestine, there followed an instantaneous, regular, and considerable contraction of the calibre of the tube (Fig. 4) close up to the divided edge, caused by the action of the circular muscular fibre. The diameter was often diminished more than half by this contraction (Figs. 1, 2, and 3). This persisted for a time, but was soon followed by an eversion of the mucous membrane, which rolled out and over the constricted portion in a remarkable manner (Fig. 3).

Fig. 3.

Fig. 4.



This protrusion of the mucous membrane forms a serious obstacle to easy and close approximation of the ends of the bowel in the efforts to bring them together by sutures; and, when turned into the bowel during such procedure, diminishes its calibre considerably, although it was not demonstrated that the obstruction was ever sufficient to prevent the passage of the intestinal contents. Several efforts were made to get rid of it, and

overcome the seeming delay caused by its presence, but all these were finally abandoned. It was pared away with the scissors; it was dissected up from the other coats for a quarter of an inch from the edges, but the conclusion was finally reach that, instead of being a harm, its presence was useful in giving support, protection, and perhaps vascularity to the freshly sutured edges; at least, in all instances in which it was removed, the stitches were found torn out and union defeated. In no case in which it was left entire, did there fail to be union in some part, and no sutures gave way when properly applied.

In all instances in which a single perforation was severe enough to require a resection of the wounded part, it was found advantageous to leave, if possible, a strip of the bowel near the mesenteric junction (Fig. 5), taking out the

FIG. 5.

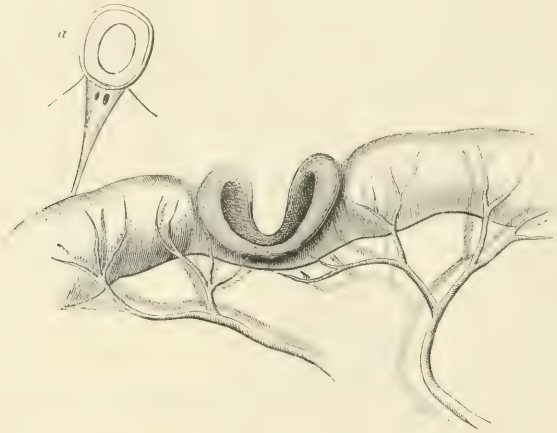


FIG. 6.

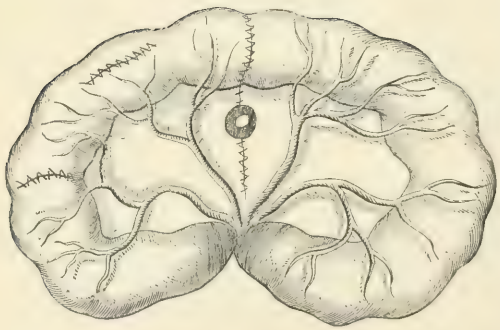

wounded portion by means of a V-shaped incision. The part left acted as a support to the wound; avoided division of the bloodvessels at this point; opposed the action of the longitudinal fibres, and in no instance in which this plan was adopted was there any appearance of separation of the wound or any displacement of stitches. In perforations through the stomach, the wound did well after drawing the peritoneal surfaces some distance from the edges thereof, over it (Fig. 6), by means of the continued suture, thus converting it into a linear wound. The same plan was adopted with success in abrasion and small perforations in the small intestines.

This way of treating the bullet openings in the bowel, is susceptible of much wider application than would appear possible at the first glance. I am quite well satisfied that it will safely take the place of excision, in not a few cases of quite severe injury. The torn edges of the wound can be turned in and peritoneal surfaces fastened together, even in large wounds, with perfect confidence in the result of safe and secure adhesion following. It seems probable that by far the greater number of successful cases will follow a single resection, even if that include a number of perforations, and involves eight or ten inches of bowel, in comparison with those cases in which several excisions are made of wounded portions widely separated.

Perforations passing through the mesenteric surface of the intestine were found the most difficult to treat, and even if slight seemed always to require a complete excision. A partial excision of this surface of the bowel resulted in an acute-angled elbow which never did well. The point of attachment of the mesentery with the bowel will usually be found the most troublesome to manage in applying the sutures in restoring a complete division. (Fig. 5, *a*.) It is quite difficult so to place the sutures as to secure a perfect reinversion of the mucous membrane, to bring serous surfaces fairly in contact with each other, and to get a sound junction.

The difficulty arises apparently from the manner in which the folds of peritoneum separate from each other

before passing on to invest the bowel, leaving a little triangular interval filled with loose connective tissue, fat, and bloodvessels. Now, if the suture fails to include the muscular coats of the intestine as well as the peritoneum at this point, the junction will surely give way and extravasation result. To make this point secure the greatest possible care must be taken in placing at least three sutures, this number being usually quite enough to include the troublesome area, and these should always be the first sutures applied. In placing the remaining sutures to complete the junction, after placing the three sutures mentioned at the mesenteric surface, it assists materially in the ease of application, saves time, and especially avoids trouble from the everted mucous membrane, to apply one at the most convex surface, and then one, half way down, on each lateral surface. After this is done the remainder can be introduced easily and rapidly. If introduced in a regular series, one after the other, all the way round, it is a very slow process, the mucous membrane is always in the way, the needle-openings in the intestines are apt to be uneven, and it is altogether the poorest plan of proceeding. The advantages mentioned as gained by taking the course suggested, are certainly all of them items of importance and have some bearing on the result; at best, these procedures will be found very prolonged and tedious. The material used by us for sutures was silk and catgut, the latter for the continued, the former for the interrupted, ligatures—No. 1 catgut, No. 2 silk. The needles were the full-curved, round needles and the ordinary sewing needle; the latter is the best. The sutures were introduced fully the third of an inch from the divided edges, made to include the peritoneal and muscular coats, and brought out just free of the edge on one side, and were then reintroduced close to the edge, and made to include about the same amount and kind of tissue on the other side, being very sure not to allow the needle to pass into the intestinal cavity. Howse, of London, proved conclusively, in his cases of gastrostomy, that the fact of entrance of the needle into the cavity of the tube, carrying the thread with it, made the difference between success and failure; cases dying from peritonitis and extravasation when the entry occurred, and recovery following when the thread included only the peritoneum and muscular coats.

Again, the everted tissue should be turned in before introducing the needle, so that it will pass through the rim of constriction; if entered too far away from the divided edge, too much tissue is turned into the intestine. When the mucous membrane was turned in and the suture tightened, two broad surfaces of peritoneum were brought in contact. This you will recognize as Lembert's suture (Fig. 6), with one change—Lembert directs that only one and a half line in width of tissue should be taken up by the suture. This amount of tissue will do very well in the closure of small slits, for which it was intended and to which it was applied, but complete resection needs a much firmer hold to withstand the strain of peristaltic movements. The fact is that it makes no difference whatever what kind of suture is used so that the principle of positively securing the application of two broad surfaces of peritoneum in contact with each other is certainly carried out. Jobert's, Gely's, and Czerny's double row of sutures were all given a fair trial; but none of them resulted as well as this. It never failed to be followed by good union when properly applied, with peritoneal surfaces brought together around the entire circumference of the intestine.

The greatest number of mishaps followed drawing the sutures too tightly, which, if done, leads to death of the applied edges and of course to failure. They must be drawn only sufficiently close to bring the surfaces fairly in contact, the subsequent swelling from obstructed circulation will hold the surfaces firmly together until glued to each other by the rapidly forming adhesive material. The interval left by the incurving of the edges of the bowel immediately after the completion of the operation, was found entirely obliterated, and the sutures covered up by effused lymph at the end of twenty-four hours. In one or two instances in which very small openings had been made in the bowel, they were occluded by passing a suture around the perforation, a short distance from its margin, pushing the wound into the cavity of the intestine, and then by tightening the suture the peritoneum was drawn together over it—a very satisfactory plan of procedure where circumstances will permit its application.

The question of the proper disposition to be made of the divided mesentery, after removal of some length of the intestine, is an important one to decide. No plan adopted proved entirely satisfactory. Previous to separation it was ligated in sections, or inclosed by a V-shaped cut (see Fig. 2); the part beyond the ligature is apt to mortify and thus prove a focus for fatal inflammation. The tissue of the mesenteric membrane is not very vascular, and the vitality of the distal portion of the stump is seemingly best provided for by causing it to adhere to surrounding vascular parts. In some cases the stumps were left free in the abdominal cavity; these all did badly, each showing mortification. In others the different sections were all included in one suture and then stitched to the bowel at the seat of operation, making as nearly as possible a continuous surface of mesentery.

These did much better, there being few instances of sloughing. When sloughing occurred it seemed to be dependent upon and to follow a too tightly fastened ligature. This method, above mentioned, of treating the divided mesentery is useful in another way; it gives support to the bowel at the point of resection; maintains the intestine in proper position by preventing bending, and also leaves fewer raw surfaces free in the serous sac. This last, a condition acknowledged to be the frequent source of serious trouble from faulty adhesion to surrounding organs, and from furnishing points from which septic absorption takes place.

A plan of dividing and treating the intestine and mesentery has been suggested to me as a possible improvement on those already noticed. It is really an application of the plan referred to above in single perforations. This is to make the separation through the intestinal walls three-eighths of an inch on either side of the mesenteric attachment, tear away the mucous lining of the retained strip of bowel, and draw the peritoneal surfaces thereof together by the continued stitch. This would avoid division of the bloodvessels going to the bowel, do away with the necessity of using ligatures, and leave no raw surfaces free in the abdominal cavity. The opening formed by its folding together where the

bowel ends are united should be closed by the continued suture.

Bleeding from slight lacerations of the spleen, kidney, or liver, can be controlled with actual cautery, lightly applied, perhaps the very best method to adopt. If the wound is a complete perforation of the body of the organ, the hemorrhage is very great, rendering extirpation of the entire organ apparently the only sure way of surmounting the difficulty.

Quite frequently the entire mass of the greater omentum seemed to require removal. The bullet in transit not only perforated it, here and there, but passed along between its folds as well, leaving injured tissue and blood-clots of considerable size in its track. These clots disseminated themselves in the meshes in such a way as entirely to prevent their removal without tearing the tissue to shreds. When this condition was present in any degree, the mass was amputated, after ligation, in sections. In a few instances, these stumps gave rise to trouble, either from recurring hemorrhage or mortification of distal end.

The circumstances under which these experiments were made, were such that it was absolutely impossible to carry ou full antiseptic appliances. The external incision was treated with iodoform and oakum or absorbent cotton, and with two exceptions healed by first intention. The bullet wounds through the abdominal walls were not probed nor disturbed in any way. Occasionally, when large and much contused, iodoform was poured on them. In only two instances did they suppurate or give rise to any trouble whatever, crusting over and healing rapidly. This result clearly enforces the rule of not disturbing the track of a bullet through the soft parts, unless the most urgent reasons call for interference. The damage of a serious nature is not in the abdominal walls but in the cavity; the nature of it can be better ascertained and the most satisfactory treatment adopted, after section through the linea alba, rather than by enlargement of the wounds of exit or entrance, if any surgical interference be instituted.

In gunshot wounds of any part of the body it is not the injured muscular tissue or fascia that causes grave concern, but the torn arterial trunk, or severed nerve, or fractured bone made by the missile, and here, too, incisions out of the course of the bullet-track often furnish the best exposure of the parts for manipulation.

None of the wounds of entrance were perpendicular to the surface of the abdomen. All were more or less obliquely directed through the component tissues of the walls, so that they were valve-like in character, and tended to close spontaneously. None of the cases presented any extravasation of the contents of the intestines through the external wounds, notwithstanding the lacerations of the tube were often very extensive, and considerable quantities of fecal matter were found in the peritoneal sac. The conclusion naturally follows that the discharge of such matters through the external openings is not of frequent occurrence after the wounds under consideration. The absence thereof is far from being proof of the non-occurrence of perforation of the intestine.

It can scarcely be expected that extravasation through the wounds in the abdomen will often happen as an immediate occurrence. This is most likely to occur, if present at all, several days after the injury, following adhesion of the bowel to surrounding parts, and the accumulation of considerable quantities of matter. There is no reason to suppose that interference with the adhesions to be met with in operations done some time after the injury, would be followed by any worse consequences than that which follows their disruption during the performance of operations for ovarian or other tumors. The hazard supposed to attend their severance is certainly exaggerated. With a clean cavity they will do equally well in all cases.

These experiments have not developed any data which will aid in the positive diagnosis of the severity or extent or kind of injury done to the viscera, or render such diagnosis less difficult than heretofore, previous to abdominal section. They go a step in advance of this by supporting the assertion that it is absolutely useless to expect immunity from penetrating injury of the intestine when the bullet has traversed the cavity. It seems —and is—infinitely more reasonable to subject the patient to the slight risk of an abdominal section, showing unwounded intestines, than to allow him to pass through the fearfully deadly peril of wounded intestines unrelieved, on the barren supposition that they may have escaped injury.

Some uncertainty is likely to arise, except in those cases showing extravasation of the contents of the bowel, or those in which the free loss of blood, as indicated by the usual symptoms accompanying such accidents, calls for aid. When doubt exists, and a critical condition of the patient argues severity of lesion, abdominal section surely seems to promise relief that can come in no other way. Exploratory incision of the abdominal walls has been done so often, and with so little hazard, as to entitle it to be classed as a procedure in itself almost destitute of danger. Such a conclusion is certainly supported by the results developed during these trials. The rule was, no trouble whatsoever from this incision.

No deduction can more justly or positively follow, as the result of these experiments, than that an incision *de novo*, through the linea alba, is the best method of procedure in the treatment of the class of wounds under consideration; a plan far preferable to enlarging either of the openings made by the bullet. It at once gives command over the entire cavity, therefore any lesion likely to result in harm is far less liable to be overlooked. It is the least vascular part of the walls; incisions thereof are more easily and perfectly coaptated than elsewhere, heal readily and soundly, and, as a consequence, the oncoming cicatrix is less likely to be followed by ventral herniæ.

39 animals were used in these experiments, exclusive of those dying from the effects of the anæsthetic. 2 of the 39 were used to demonstrate the effects of closure of the main branches of the mesenteric artery upon the nutrition of the intestines. Of the remaining 37, 3 cases died immediately after the shot, or from the effects of profuse hemorrhage, one having a division of the aorta just below the mesenteric artery; the second had a large laceration of the kidney, with a wound of the renal artery; the third, a laceration of both kidney and spleen. One case, No. 4, had tetanus three weeks after operation, and is given a special position, simply owing to the presence of this condition as a complication in the case. The post-mortem examination, as already mentioned, developed other conditions which would

have caused death, and which were, no doubt, the cause of the tetanic convulsions. 12 of the remaining cases died inside of twenty-four hours, either from severe primary or recurring hemorrharge, and the effects of the very extensive character of the wounds. 2 out of this 12 were cases requiring removal of the pregnant uterus, accompanied with many perforations of the bowel. Death in both occurred from secondary hemorrhage from uterine stumps, the ligature having slipped. 3 more had slight lacerations of the spleen and numerous perforations of the intestine. The spleen was removed and several inches of the tube excised in each case. In 3 others, from twelve to twenty inches of the bowel were excised, and many arterial trunks severed. 1 of the 12 had rapid mortification of five or six inches of the entire calibre of the bowel, apparently dependent upon the division of two large mesenteric arteries by the bullet, and also the resection of six inches of the intestine. The remaining 3 of the number dying inside of twenty-four hours are classified as having died of shock. In all of them the damage done by the missile was of excessive severity. The bullet was of large size (38 or 44 calibre), and the firearms possessing great penetrating and lacerating power. There was not manifested in any case any recognizable evidence of shock aside from that following great loss of blood. The transit of the bullet made no noticeable impression upon the pulse or respiration. In every instance in which signs of severe prostration became manifest, through change in respiration or weakening of pulse, there was found profuse hemorrhage to account for such condition. I am inclined to infer that the cases are exceptional, indeed, in which purely nervous shock will give rise to symptoms severe enough to mislead one to perform an unnecessary ventral section; rather, when severe constitutional manifestations follow the passage of a bullet through the abdominal cavity, good cause for them will be found, as soon as the cavity is opened, in wounded viscera or bloodvessels, and this course will often be the only possible way of either actually saving life or even prolonging it. None of these 12 cases could possibly have lived longer than twenty-four hours after the injury received. Most of them would have died much sooner without the control of hemorrhage alone made possible by the opening.

Two cases of the series were subjected to the expectant treatment. These cases were chosen because their injuries did not seem very severe; the hemorrhage was not great and the prostration not extreme. Both died: the first in one day; the other lived five days. Post-mortem examination showed extensive extravasation of the contents of the bowel and septic peritonitis. In one case an attempt was made to establish an artificial anus. The wounded intestine was resected and the ends fastened to the edges of the abdominal incision. The animal died of septic peritonitis in three days. This trial was made early in the experimentation, before any definite plan of procedure had been settled upon. This is the only experiment that has given rise to any regret, for I feel satisfied that with a fair junction of the bowel and a clean abdomen, the animal would have been saved. 18 of the 37 have thus far been accounted for; of the remaining 19, 10 died, and 9 recovered.

The 10 fatal cases lived from three days to three weeks. Peritonitis, from one cause or another, seemed to be the precursor of death. In 6 of them, mortification of the ligated stumps of the divided mesentery, together with mortification of the edges of the recently united bowel, was present. In the one that lived three weeks, death was the result of intestinal obstruction caused by the adhesion of a fold of the intestine to the stump of mesentery left free in the cavity. An acute flexure was produced at the point, against which the contents of the bowel had accumulated in large quantity. A rupture was found above this mass, through which extravasation had taken place. The inflammation was so intense that everything was matted together, and the specimen so horribly offensive it could not be preserved. There was no separation at the point of operation on the bowel; it was thicker here than elsewhere, but full distention with water was allowed without leaking. All of these cases demonstrate conclusively the necessity of great care in the manner of dealing with the divided mesentery, and in the application of the sutures which bring the separated bowel ends together. The remaining four furnished evidence of separation of the recently united parts of the intestine at the mesenteric junction. In all of them the thread failed to include the muscular and fibrous coat of the bowel, holding only the peritoneum; the result was extravasation, and death followed.

It may be a matter of surprise to you that the percentage of successful cases presented is so small—9 out of 19—so few out of so many. To me, knowing well the extremely adverse circumstances under which these experiments were performed, it is a matter of astonishment to have so many recoveries included in so few cases. It is suggestive to remember that all the recoveries followed the use of the modified Lembert's method of bringing the peritoneal surfaces together, while in many of the failures trials were made of other methods. Full six weeks have gone since the last case, followed by recovery, was subjected to operation. The first favorable case was treated four months ago. None of the animals present any evidence of being other than in their usual good health. The longest resection of intestine among the recoveries, measured over six inches, and included four perforations.

It is scarcely possible to do work of any kind under more disadvantageous surroundings than accompanied the performance of these experiments. The operative work was carried on, and the animals kept, in the prosector's room of a medical college during the winter session, in the midst of the odds and ends and bad hygienic conditions of such a place. No better accommodations could be secured, The labor has been purely one of experimental inquiry and not a striving after recoveries implying a choice selection of attending circumstances and special preparations to that end. Therefore I judge it proper and fair to claim the results as satisfactory. These results certainly indicate that a better showing is likely to follow where more satisfactory control can be had, over both patients and surroundings, than was present during these examinations. They clearly demonstrate that a hopeful expectation of recovery may be entertained after operation, and suggest the nature of the injuries produced, what accidents to avoid, and what treatment to adopt.

My confidence in coming before you with no better record is assured, when I remember that all of you are well aware of the great mortality of these injuries, under

all circumstances. It must be large surely, when Dr. Otis, in the *Surgical History of the War*, says that the authenticated cases of recovery can be counted on the fingers of one hand. It cannot be said that operative interference in these cases has as yet an established position. Still, perhaps, Dr. J. Marion Sims looked with prophetic eyes upon the future, when he closed the article already referred to with the following words:

"I have the deepest conviction that there is no more danger of a man's dying of a gunshot or other wound of the peritoneal cavity, properly treated, than there is of a woman's dying of an ovariotomy, properly performed. Ovarian tumors were invariably fatal, till McDowell demonstrated the manner of cure, which has now reached such perfection that we cure from ninety to ninety-seven per cent. of all cases. And by the application of the same rules that guide us in ovariotomy, to the treatment of shot wounds penetrating the abdominal cavity, there is every certainty of attaining the same success in these, that we now boast of in ovariotomy." (*British Medical Journal*, March 4, 1882.)

In a rather quaintly written but richly laden book on surgery by Herr L. Heister, Prof., etc., written in 1739, there occurs this passage:

"When the intestines are wounded but not let out of the abdomen, and therefore their wounds are out of reach, the surgeon can do nothing but keep a tent in the external wound, according to the rules laid down at Chapter V., and after this, bleed the patient if his strength will admit of it, advising him to rest, eat abstemiously, and to lie upon his belly; the rest is to be left to Divine Providence and the strength of his constitution. But the question may be asked here whether a surgeon may not very prudently, in this case, enlarge the wound of the abdomen, that he may be able to discover the injured intestine, and treat in a proper manner. Truly I can see no objection to this practice, especially if we consider that upon the neglect of it certain death will follow, and that we are encouraged to make trial of it by the successes of others. Sacherus, in Programmata Publico, Lipsiae, ed. 1720, mentions a surgeon who performed this operation successfully."

A period of one hundred years and more has rolled away since Dr. Heister published his belief and reported recovery, to the time when Dr. Sims expresses his convictions—over a century of doubts, timidity, uncertainty and gloomy misgivings, lightened only occasionally by some bold and resolute assertions. The future asks for action, and it is not unreasonable to assert that careful trials will accomplish successful results.

Avoiding any spirit of dictation, it seems proper to tabulate the following conclusions as an outgrowth of the experiments:

1. Hemorrhage following shot wounds of the abdomen and the intestines, is very often so severe that it cannot be safely controlled without abdominal section; it is *always* sufficient in amount to endanger life by secondary septic decomposition, which cannot be avoided in any other way than by the same treatment.

2. Extravasations of the contents of the bowel after shot injuries thereof are as certain as the existence of the wound.

3. No reliable inference as to the course of a bullet can be made from the position of the wounds of entrance and exit.

4. The wounds of entrance and exit of the bullet *should not be disturbed* in any manner except to control bleeding or remove foreign bodies when present. They need only to be covered by the general antiseptic dressing applied to the abdomen.

5. Several perforations o the intestine close together require a single resection, including all the openings. Wounds destroying the mesenteric surface of the bowel always require resection.

6. The best means of uniting the wounded intestine after resection is by the use of fine silk thread, after Lembert's method. It must include at least one-third of an inch of bowel tissue, passing through only the peritoneal and muscular coats, never including the mucous coat. The everted mucous membrane must be carefully inverted, and needs no other treatment.

7. Wounds of the stomach, small perforations, and abrasions of the intestine, can be safely trusted to the continued catgut suture.

8. Every bleeding point must be ligated or cauterized, and especial care devoted to securing an absolutely clean cavity.

9. The best method of treating the stumps of divided mesentery is to secure them to the intestine at the site of the resection; or, better, to leave the mesenteric surface of the bowel as indicated above. Still this requires further study.

10. *Primary abdominal section* in the midline gives the best command over the damage done, and furnishes the most feasible opening through which the proper surgical treatment of such damage can be instituted. Further, its adoption adds but little, if anything, to the peril of the injury.

11. Is not the moral effect of the assurance to the patient, that he will be placed in a condition most likely to lead to his recovery, a good substitute for the mental depression accompanying the general and popular conviction that his wounds mean certain death?

MEDICAL PROGRESS.

VESICATING LIQUIDS.—At the meeting of the Société de Médecine Pratique, on February 21st, M. DELTHIL presented a vesicating liquid composed of a solution of cantharides in acetic acid, which offers several advantages over the ordinary plaster masses. It is applied in coats by means of a brush. The first coat produces a rubefacient effect, the second a slight vesication, the third ordinary vesication, and the fourth very great vesication.

The advantages of this liquid are numerous: 1. Its action is limited and fixed; 2. Its uid state enables one to apply it to all parts of the body where its employment may be necessary; 3. It is more acceptable to patients, and its action is perhaps less painful than that of ordinary vesicants; 4. It acts more quickly than plasters; 5. The various effects may be obtained by adding to the number of coats; 6. Its advantages are especially seen when used on children.

The action of the liquid may be limited to the desired space by cutting an opening in a piece of cere cloth, as in the application of Vienna paste. Before applying it the surface of the skin should be washed in warm water, and then rubbed dry and red; after applying the desired number of coats, the spot is covered with wadding.—*Journal de Méd. de Paris*, April 5, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 17, 1884.

SCHOOL HYGIENE.

THE question of school hygiene, in which the people are universally and deeply interested, has of late attracted unusual attention, and its discussion is yielding important results. Careful and searching inquiries into the sanitary surroundings of school life, which are being conducted in many localities, reveal a condition of affairs too frequently at variance with the laws of hygiene and sanitary science. These investigations all tend to show that the regulation of school architecture, appointments, and management in accordance with the requirements of sanitary laws, is one of the pressing necessities of the day. Progress is being made in many directions, but it is insignificant when considered in relation to the vastness of the field yet to be improved. Prejudice, associated with a doubt of the need of the proposed innovations, and the cost which they entail, and ignorance of the real necessities of the case, are some of the obstacles to the readjustment of school construction and school administration in conformity with the established principles of hygiene. The remedy is diffusion of knowledge by persistent appeals to the public through the press and other agencies, the free exposure of existing faults, and the reconstruction of school boards and health boards in harmony with enlightened sanitary knowledge.

These remarks have been suggested by the results of a recent inquiry into the sanitary condition of the school-houses of Lynn, Massachusetts, which has revealed numerous defects, prominent among which are those in relation to the important particulars of lighting and ventilation. Massachusetts was among the first, if not the first State, to organize a State Board of Health, which from the beginning has made signal endeavors to improve the sanitary condition of the public schools. Other agencies have been at work, with this same laudable object in view. If in a State in which great attention has been given to the subject, notable examples of neglect of the fundamental principles of school hygiene are found to exist, as exemplified by the city of Lynn, it is fair to presume that elsewhere careful investigation is all that is needed to reveal equally bad, if not worse, examples of neglect.

New York and Brooklyn are now agitating this subject, in view of the unfavorable results of a recent sanitary inspection; and Philadelphia is disquieted because of the unsatisfactory sanitary condition of some of the public schools, which has been brought to light by a partial inspection by the Board of Health.

In Lynn a very prominent fault was insufficiency and objectionable arrangement of light. The construction of the buildings and the arrangement of the desks plainly indicated a want of information in regard to the ratio of window surface to floor space, and the proper arrangement of light required in school-rooms.

Especial attention was also given to the subject of ventilation. The amount of carbonic acid present in the air being taken as a measure of its impurity, it was found that in most of the rooms the air was *very bad*. Careful analyses showed the presence of from 12 to 29 parts of carbonic acid per 10,000 volumes of air, which is a rather startling exhibit when we reflect that 6 parts per 10,000 is the limit beyond which the air is unfit to breathe. In most of the rooms there were less than 200 cubic feet of air per scholar; in some the proportionate amount was only a little over 100 feet. This allotment would require a very frequent change of air every hour to supply the necessary amount of oxygen to each pupil, which it would not be possible to make without creating objectionable draught. The means of ventilation were found to be very inadequate. Under the above conditions of impurity, the air has a devitalizing influence; it enervates the system, impedes healthy development, and lessens the power of resistance against disease, and favors the chances of infection should disease-germs be present in the air.

The experience gained by the inquiry at Lynn is another argument in favor of regular, systematic inspection of schools by competent medical officers. The evils must first be detected before the remedy can be applied, and in no way can this be accomplished with greater certainty and better effect than by entrusting the hygienic supervision of schools to medical officers trained to the work.

DISCUSSION ON TUBERCULOSIS AT THE AMERICAN MEDICAL ASSOCIATION.

THE discussion on "Tuberculosis" at the late meeting of the American Medical Association failed to elicit any results of importance. It revealed, in the first place, that none of those who took part in it had been engaged in practically investigating the subject, except the author of the paper—Dr. Formad, Dr. Ernst, of Boston, and, perhaps, Dr. Welch, of New York; and of these, apparently, Dr. Formad alone had made extensive inoculations with cultures of the bacillus and with indifferent substances.

Dr. Formad's paper was imperfect in that it failed to present in a systematic way the results of his experiments, it having been deemed expedient for some reason that the publication of these should be, for the present, deferred. This, of course, weakened the position he took against the bacillus theory and against the view that tuberculosis is contagious or or even infectious. On the other hand, the replies of those who were arrayed against him consisted mainly in a criticism of his methods, against which some very unfounded aspersions were made, and of his results, in the discussion of methods of staining bacilli, and in the narration of a few facts bearing upon the contagiousness of tuberculosis.

Notwithstanding the fact that the almost unanimous voice of the Section was against Dr. Formad, the only *facts* adduced which actually tended to aid in the solution of the question were those drawn from his own experience by Dr. Traill Green, of Pennsylvania. This veteran member of the Association, characterized at once by his mature years, his ripe experience, and clear head, recalled his experience, of which he had had much, with those engaged in the making of grindstones, many of whom, entering the works with all the vigor and strength of youth, succumbed in a couple of years, despite all precautions, to tuberculosis due to the inhalation of the flinty particles thrown off in grinding the stones. On those dying thus he had made numerous autopsies, and found cavities of large size, together with the other well-known signs of tubercular phthisis. Here, certainly, he said, we have the operation of a cause distinct from the bacillus tuberculosis.

It became evident, too, from the discussion, how very few actual experimenters we still have among us, qualified by their own experience to sit in judgment on those important questions of pathology of which tuberculosis is one.

CREMATION.

THE adverse action taken by the British Parliament last week upon the bill for legalizing cremation, was more than counterbalanced by the practical endorsement of the system in the case of the illustrious Gross, whose remains were cremated at Washington, Pa., in fulfilment of the expressed wish of the deceased. This celebrated example of consistent advocacy of an innovation founded upon strictly scientific and sanitary principles will exert a world-wide and potent influence in favor of the practice, which has much to recommend it, and which is especially applicable to the great centres of population. That there should exist a deeply rooted prejudice in favor of inhumation is natural enough, since the custom has been universally adopted by Christian nations for many centuries. It is not to be expected that such a prejudice, founded upon a universal sentiment, and fostered by the influence of long-continued habit, will yield lightly to arguments based upon expediency and the teachings of sanitary science.

The difference between inhumation and cremation is merely that of mode, the ultimate results being the same. The disintegration of the body in either case is produced by oxidation. In the one case by the slow and corrupt process of putrefaction; in the other by the rapid and purifying action of intense heat, the constituents of the body being converted quickly and harmlessly into gaseous vapors and ashes by the oxidizing agency of fire. From a sanitary standpoint, the advantages of the latter method of disposal of human remains are incomparably superior to those fancied to be associated with the common practice of interment. The sudden transformation to a mass of unrecognizable ashes of the forms of those we have loved and reverenced in life, and love to think of as slumbering undisturbed beneath the sod, does violence to our feelings and shocks our tender sensibilities. But did we reflect upon the ghastly picture of what actually happens when the body is consigned to the earth, there would be less reason to decry a practice which is scientific, rapid, and complete in its execution, and which is devoid of danger to the living.

Cremation is beginning to be recognized as a necessity in very populous places. It rests upon the broad basis of verified sanitary principles, and must eventually succeed in its application among civilized people. The example which we have chronicled is notable because of the personage and of its exceptional character. It is a grand illustration of the influence of a conscientious conviction, derived from an unbiassed study of the question, upon a mind of extraordinary grasp and foresight, and possessed of courage which was not deterred from acting upon such a conviction in the face of widespread prejudice. This closing scene in the drama of a great and eventful life is characteristic of the man, and will not be without its lesson of instruction.

LABOR AND PUERPERALITY IN OLD PRIMIPARÆ.

How far childbirth and lying-in are unfavorably affected by the primipara being old when she first is

a mother, is a question to which considerable professional attention has been given, though probably not as much as it needs. We, therefore, turn with interest to a recent paper by Dr. F. Steinmann, of St. Petersburg, in the *Archiv für Gynäkologie*, 1884, Heft 3, in which he observes that the estimate of the time when a primipara is called old varies between twenty-five years (Fasbender) and thirty-five years (Mangiagalli), but he accepts that which most authorities have adopted—to wit, thirty years. By the way, it of course follows that when a woman marries at twenty-nine years she is an old bride, a truth which one would hardly dare to utter in polite society. Dr. Steinmann's cases are taken from twelve years' statistics of the Petersburg Maternity, during which time there were 28,279 deliveries, and of the women delivered, 645 were old primiparæ. Of the 645, a fraction over 69 per cent. were 30–34; 26.2 per cent. 35–39, and 4.2 per cent. 40 years and over: one of these was fifty-two years old.

A very instructive table of the general mortality of lying-in women and of old primiparæ is given, presenting some very marked contrasts. Thus, in 1875, when the general mortality was three a half per cent., that of old primiparæ was nearly fourteen per cent.; and, again, in 1881, when that of the former was only a half per cent., that of the latter was eight per cent. Certainly, the facts adduced by Dr. Steinmann, which also show a decidedly greater fœtal mortality occurring when primiparity is late, are a strong objection to late marriages.

CORROSIVE SUBLIMATE IN OBSTETRIC PRACTICE.

By general consent, corrosive sublimate has been accepted as the most useful antiseptic, or germicide, in obstetric practice, and its safety has not been disputed. Recently, however, Stadtfeld, of Copenhagen, has published in the *Centralblatt für Gynäkologie* a case in which death, believed to be due to mercurial poisoning, followed an intrauterine injection of corrosive sublimate, the strength of the solution being 1 to 1500. This is altogether an exceptional result, and, beside, the strength of the solution was greater than that commonly used for such injection.

Stadtfeld further objects to the corrosive sublimate because weak solutions, having neither taste nor color to indicate the character of the fluid, may cause serious mistakes; but, to prevent such mistakes, it has been proposed to color the liquid with a small quantity of methyl blue or fuchsine. Really, however, mistakes are almost infinitely improbable, for usually the bottle containing the corrosive sublimate solution is very much larger than a bottle having medicine for internal administration, and besides is plainly marked by the word *Poison*. If we are to reject all colorless and tasteless solutions of medicine which are dangerous in improper doses or uses, our therapeutics will become greatly restricted in some directions.

THE PROGRAMME AT THE LATE SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

We have already said that, on the whole, the recent meeting of the American Medical Association may be regarded as successful. At the same time there were some defects, the calling of attention to which at this date may serve to prevent a repetition next year. The chief of these was that the programme was over-full. It is creditable, of course, to a chairman of a Section to have secured a full programme, but he should, at the same time, see that those whom he invited to prepare papers, some of whom may have come a great distance for this purpose, shall have the opportunity of so doing. Experience has shown over and over again that very few papers offered at the Association can be disposed of in twenty minutes. At the late meeting, several occupied an hour, and some took even more time, including the discussions. This being the case, it is evidently impossible to dispose of nine papers, in a period of three and a half hours. It is evident, too, that one-half that number would have been fully enough for an afternoon's work, especially if one is on a subject calculated to invite discussion, as is always desirable.

Again, all remarks in discussion should be limited to ten minutes. Such remarks are not intended to be disquisitions, and if limited to points brought out in the original paper can easily be included in that time, often, indeed, in less, and where more time is taken, they oftentimes resolve themselves into mere repetitions. It is also objectionable to permit the reading, under the head of discussion, of written essays of considerable length, having in some instances no relation to the points brought out in the original paper, as was done at the late session.

Finally, no paper should be permitted to come up out of its place, or at a fixed time, to the exclusion or precedence of papers on the programme before it. Such a course is obviously unjust to those who happen to precede and who are excluded thereby from reading papers. The programme should be literally followed out in the order printed.

We venture to suggest that, if the above points are remembered at another meeting, it will prove, as far as scientific work is concerned, even more successful than the one just terminated; and there will be, certainly, less dissatisfaction on the part of those whose papers are of necessity left unread, and whose participation in the work gives character to the proceedings.

SOCIETY PROCEEDINGS.

THE AMERICAN MEDICAL ASSOCIATION.

Thirty-fifth Annual Meeting, held at Washington, May 6, 7, 8, and 9, 1884.

(Specially reported for THE MEDICAL NEWS.)

FRIDAY, MAY 9TH—FOURTH DAY.

GENERAL SESSION.

THE Association was called to order at 9.30 A.M.

DR. J. C. DALTON, of New York, offered the following resolutions on behalf of the Committee on

EXPERIMENTAL MEDICINE:

Resolved, That the Committee on Experimental Medicine be empowered and instructed to add to its number and efficiency by the election of associate members from different States, and that it report to this Association at its annual meeting, any matters relating to the subject of experimental medicine which may need the consideration or action of the Association.

Resolved, That in view of the attempts that have been or may be obstructed by restrictive legislation, in the progress of experimental medicine, this Association desires to express its earnest conviction that experimentation on animals is a most useful source of knowledge in medical science; that it is the means by which many valuable discoveries, both practical and scientific, have been accomplished; that its direction and supervision can be properly entrusted only to members of the medical profession; and that its restriction or prohibition by law would inevitably retard the advancement of medical science and the improvement of the medical art. Unanimously adopted.

The Committee on the

NOMINATION OF TRUSTEES OF THE JOURNAL,

reported that the names offered by the Committee were the same as those chosen by the Committee on Nominations as reported yesterday. However, as they believed the action of the latter committee was unconstitutional, they begged that the error be not permitted to go on the records of the Association, but that the action of the Special Committee be approved. A delegate then moved that it be declared the sense of the Association that the Trustees be nominated by the Nominating Committee, in the same manner as other officers of the Association are nominated.

DR. N. S. DAVIS stated that, by reference to the minutes of the Association, it would be found that special action had been taken as to the appointment of these Trustees, in the report of a committee of which Dr. Packard was Chairman, and which was adopted at St. Paul, in 1882, it being therein provided that the Trustees be appointed by a special committeee of seven appointed by the President.

The original motion was then withdrawn and a substitute adopted, that hereafter the appointments be made by the regular Committee on Nominations.

DR. AUSTIN FLINT, as Chairman of the Committee to draft resolutions on

THE DEATH OF DR. GROSS,

reported that it had been impossible to get the Committee together, and asked that the Committee be continued, with power to report in print.

The report of the Committee to consider the

RECOMMENDATIONS CONTAINED IN THE PRESIDENT'S ADDRESS

being called for, DR. N. S. DAVIS stated that some of the gentlemen appointed had left the city, and that the remaining members of the Committee considered it not expedient at present to take any action on the Code of Ethics. They believed that any declaration of this nature should be made only after due deliberation. Dr. Davis then presented, on his own responsibility, the following preamble and resolution:

Whereas, Persistent misrepresentations have been and are being made in regard to the Code of Ethics of this Association, therefore,

Resolved, That the President appoint a committee of five, of which he shall be a member, to report at the next meeting of the Association such explanatory resolutions as the committee may deem proper. Adopted.

DR. GARCELON, of Maine, stated that the Nominating Committee had failed to appoint a member of the Committee on Necrology for the State of Maine. He therefore nominated Dr. Seth Gordon, of Portland, and moved his election. Carried.

DR. DEERING J. ROBERTS, of Tennessee, then delivered the

ADDRESS IN STATE MEDICINE.

He defined the object of the Section to be the application of medical science to the good of the State. Reference was made to the recent and more remote discoveries in medicine, among others to the germ-theory of the origin of diseases. The honor of this discovery he attributed to two Tennessee physicians—Drs. Campbell and Thomas—who, he announced, had discovered the germ of cholera thirty years ago.

The power of sanitary medicine to prevent the spread of disease was illustrated by the recent limitation of the spread of cholera in the East, and of yellow fever in the South. Some remarks were made upon the importance of medical education. He expressed himself as very decidedly opposed to legislation to regulate the practice of medicine, and referred to the notable discoveries, etc., which were made before any such regulation was attempted, also quoting the remarks of the distinguished Daniel Drake, that little or no good is done by laws of that character, and that he did not think the laws of New York and Ohio, which in his time stood alone in that respect, were of any advantage to those States. He also referred to the more moderate views of Prof. Huxley on the subject. He approved of the work of the National Board of Health, as well as of that done by the Marine-Hospital Service, and regretted that any contest should have arisen between them. He then favored certain legislation in regard to medical and sanitary purposes, among other things suggesting the propriety of the President of the United States establishing a Health Department, the chief of which should constitute another member of his Cabinet, with compensation and rank the same as those of the present Cabinet Officers, and whose duty it should be to inspect the working of sanitary measures and suggest to the President from time to time such improvements as might be demanded, and to appoint all necessary assistants and officers.

MISCELLANEOUS BUSINESS.

It was then announced that Dr. Smith Townshend, who was appointed to represent the District of Columbia in the Committee on Necrology, was ineligible to the office, because he had not been a delegate to this meeting of the Association. Upon motion, Dr. Thomas Antisell, of Washington, was appointed in his place.

DR. CHANCELLOR, of Virginia, stated that his name had been placed on the Committee on State Medicine, but that, as he would be unable to serve on the committee, he respectfully requested to be relieved of the appointment.

THE PRESIDENT then announced the following as

THE COMMITTEE ON THE INTERNATIONAL MEDICAL CONGRESS,

which it was proposed should be invited to meet in this country in 1887: Drs. Austin Flint, of New York; I. Minis Hays, of Philadelphia; L. A. Sayre, of New York; Christopher Johnston, of Baltimore; G. J. Engelmann, of St. Louis; J. S. Brown, U. S. N.; J. S. Billings, U. S. A. The Committee was vested with power to augment its numbers.

DR. JOHN H. PACKARD, of Philadelphia, asked that

THE AMENDMENT TO THE CONSTITUTION

which was proposed at the meeting of the Association at St. Paul, in 1882, should now be brought before the assembly for action. The amendment, as read from p. 577 of the volume of *Transactions* for 1881, was "Members by application shall consist of such members in good standing in County or State medical societies as shall make application in writing for such membership." Dr. Packard had offered a paragraph in addition, so that it should read, "Membership shall be acquired by any one received as a delegate; or upon the application of any member in good standing of a State or County society recognized by this Association, the application being accompanied by a certificate from the President and Secretary of his society, testifying to the good and regular standing of the applicant. Members by application shall remain such so long as they shall continue in good standing in their local society and in this Association, and pay regularly their annual dues." The mover of the amendment stated that he believed a measure of this nature would increase the financial income of the Association to an extent that would aid it very materially in carrying out its objects.

DR. J. M. TONER, of Washington, objected to taking action upon this amendment, since it should have come up at the meeting last year, and, having failed in that, it was not allowable, he said, to bring it up now.

DR. J. S. BILLINGS asked, in order to adjust matters, that the amendment be now presented for action at the next meeting.

DR. KINLOCH finally moved that, since it was evidently the spirit of the By-Laws, if not the letter, that amendments be before the Association long enough to be thoroughly understood, and not for any arbitrary period, the amendment offered should be adopted. The motion was carried.

In reply to a question whether members by application should be entitled to a vote in the proceedings of the Association, it was stated that, according to the Constitution, none but delegates had that right.

DR. C. H. VON KLEIN, of Ohio, announced his intention to offer an amendment providing that the Association shall, in the future, no longer receive delegates who are not graduates of medical colleges which require a thorough preliminary education of their students.

SECTIONS TO NOMINATE THEIR OWN OFFICERS.

DR. FOSTER PRATT, of Michigan, moved the following:

Resolved, That the By-Laws be so amended as to require that each Section shall, in the future, elect its own chairman and secretary, other nominations to be made as heretofore.

MISCELLANEOUS BUSINESS.

DR. KELLER, of Arkansas, asked that his resolution on cremation be referred to the Committee on State Medicine. Granted.

DR. ROBERTS, of Tennessee, offered a vote of thanks for the invitation to visit the Museum of Hygiene, and moved that Congress be petitioned to place the Museum on a substantial financial basis; also to provide for it a new home. Adopted.

REGISTRATION.

A resolution was adopted requiring that the Committee on Arrangements and the Permanent Secretary shall provide a method of registration by which delegates may send in their applications and receive cards of membership by mail previous to the date of meeting.

THE NOMINATING COMMITTEE INELIGIBLE TO OFFICE.

A motion was made that it is the sense of the American Medical Association that it is not expedient for the Nominating Committee to nominate any of its own members for election to the offices of the Association.

IMMIGRATION OF THE DEFECTIVE CLASSES.

The resolution offered by Dr. Pratt in the Section on State Medicine was offered and adopted.

A motion was then carried to defer the remainder of the business until after the delivery of the addresses set for the day.

A motion was also passed requiring that the papers remaining upon the programme should be read by title and referred to the Committee on Publication.

DR. J. J. CHISOLM, of Baltimore, who was to have delivered the

ADDRESS ON OPHTHALMOLOGY,

stated that he had intended delivering an address, not so much on the subject of the recent advancement of this department, as to call attention to the need of a more general diffusion of knowledge in this important branch. There are many facts, he said, that have been well established by the specialists which should be in the possession of the general practitioner, but which are generally overlooked by him.

DR. WILLIAM LEE stated that the subject of his

ADDRESS ON DISEASES OF CHILDREN

was "The Recent Advances in the Study of the Infectious Diseases in Children." He regretted very much not being permitted to read his paper, as he considered the subject an important one. The paper was referred for publication.

DR. T. W. BROPHY stated that he had prepared his

ADDRESS ON ORAL AND DENTAL SURGERY,

and had taken for his subject "The Importance of Establishing in Our Medical Colleges a Chair of Oral and Dental Surgery." He also regretted being deprived of the privilege of reading a paper on a subject which he considered so important. The paper was referred.

THE REPORT OF THE COMMITTEE ON NECROLOGY

being called for, DR. J. M. TONER, the Chairman, stated that the works of the Committee had been published regularly in the *Journal* of the Association, and that hence his report had virtually been submitted. He stated, also, that, if agreeable to the Association, the Committee would continue that method of making their report.

STATE CONTROL OF MEDICAL EDUCATION.

DR. FRANZONI offered a resolution that in view of the fact that there was a movement on foot in some of the States to secure a better preliminary education of medical men, as well as to raise the standard of medical education, and in view of the importance of having the same standard adopted, it should be resolved that the members of the American Medical Association in the different States, should endeavor to secure the passage by Congress, or the several State Leislatures, of bills requiring candidates for the degree of M.D. to pass an examination, in all the branches of the medical sciences, before a board appointed for the purpose.

DIVISION OF THE SECTION OF OPHTHALMOLOGY AND OTOLOGY.

DR. CARL SEILER, of Philadelphia, offered an amendment to the By-Laws, providing for the division of the Section on Ophthalmology into two sections, one to include ophthalmology and otology, the other, laryngology, rhinoscopy, etc.

THE REPORT OF THE TREASURER,

DR. R. J. DUNGLISON, showed a balance in the treasury of $2212.07. The report showed no difference in the sources of revenue, except that subscriptions to the *Journal* and payments for advertisements therein, had been added. The report stated that it was the custom of a large number of members apparently to comply with the By-Laws by paying dues for about two years in three, instead of paying annually, and the Treasurer asked that a resolution expressing the sense of the Association in this regard, should be presented.

DR. BRODIE moved the following:

Resolved, That it is the sense of this Association that the continual payment of annual dues shall be necessary to the continuance of membership.

LIBRARIAN'S REPORT.

The Librarian reported that two hundred and forty-nine volumes have been added to the library during the past year, making a total of two thousand and sixty-six distinct titles, or about six thousand volumes, including pamphlets.

THE MEDICAL AND SURGICAL HISTORY OF THE WAR.

DR. J. C. GREENE, of Buffalo, offered the following preamble and resolution:

Whereas, The first edition of the *Medical and Surgical History of the War of the Rebellion* has been long since exhausted, being so distributed by the members of Congress at the time the several volumes were published, as to leave but a small number of volumes for general distribution; and

Whereas, Nearly every physician and surgeon desires to obtain the volume; and

Whereas, The third volume of the *Medical History* has not yet been completed, which is necessary to complete the entire work, therefore,

Resolved, That it is the desire of the American Medical Association that the third volume should be issued at the earliest possible date; also, that Congress be respectfully requested to issue an entire edition of the work known as *The Medical and Surgical History of the War of Rebellion*, to be disposed of at cost, plus the ten per cent. required by law. Adopted.

PLEURO-PNEUMONIA AMONG CATTLE.

DR. BEACH, of Ohio, presented the following resolution, which was adopted:

Resolved, That the members of the American Medical Association consider it important that proper legislation be had before the adjournment of the present session of Congress, to provide for the extermination of the disease among cattle, known as pleuro-pneumonia.

INTRODUCTION OF THE PRESIDENT-ELECT.

DR. HENRY F. CAMPBELL, of Augusta, the President-elect entering the hall, was conducted to the platform.

DR. FLINT in introducing him said: "I have had somewhat the feeling of an usurper since the last meeting. I have felt that I occupied a position to which I had no claim. But that feeling is somewhat ameliorated to-day by the privilege I have of introducing to you my successor. I can freely express the assurance, in which you will all join me, that the duties of the office and the interests of the Association will be well cared for in his hands."

DR. CAMPBELL, in reply said: "I cannot let those remarks pass without a reply. Instead of a usurper, he has honored the place and made the chair—the throne—that I am to occupy more noble. I am highly gratified at being elected the President of the American Medical Association, and I will endeavor to sustain the honor of my office, the dignity of the profession, and the ethics of the Association."

MISCELLANEOUS BUSINESS.

DR. GARNETT moved a vote of thanks to the Postmaster of Washington City for establishing a branch office in the place of meeting, for the Association.

DR. BRODIE offered a resolution that the Board of Trustees be authorized to procure hereafter a stenographic report of the proceedings of each meeting, to be published with the minutes of the Association.

DR. VON KLEIN offered a resolution that the custom of opening the sessions of the Association with prayer be dispensed with. A motion to lay the resolution on the table was unanimously carried.

DR. VON KLEIN offered a resolution that, as a fitting mark of respect to the late lamented Dr. S. D. Gross, the next issue of the *Journal* of the Association be draped with mourning. The resolution was referred to the Special Committee, previously appointed.

DR. LEASURE offered the following, which was adopted:

Resolved, That the Association protest against its members signing certificates as to the action and remedial powers of various proprietary or trade-mark preparations, mineral waters, etc.

A communication was read from the West Philadelphia Medical Society, protesting against the attempts of certain mercenary persons to lay aside the principles of the Constitution of the Association, and the Code of Ethics. A motion to lay on the table being lost, it was referred to the Judicial Council.

A resolution was adopted asking Congress to enact laws which shall require the labelling of all such articles as caustic potash or soda, concentrated lye, etc., as poison, and the regulation of their sale, the same as all other deadly poisons.

COMMUNICATIONS.

A communication from the New Jersey State Medical Society was partially read and referred to the Committee on Publication.

A communication from the St. Louis Medical Society relative to the methods of advertising in use by medical colleges was referred to the Judicial Council.

THE CHAIR announced the appointment of the following

DELEGATES TO FOREIGN SOCIETIES:

To the Canada Medical Association, Drs. William Brodie, W. S. Tremaine, E. N. Brush, and H. O. Walker.

To the British Medical Association, Dr. William Brodie.

To the International Medical Congress, and any other European association that the delegates may choose to attend, Drs. J. W. S. Gouley, of New York; H. D. Didama, of New York; C. C. Wyckoff, of New York; F. Hyde, of New York; W. H. Daly, of Pennsylvania; L. Friederich, of District of Columbia; J. M. Browne, U. S. N.; D. W. Prentiss, of District of Columbia; N. C. Husted, of New York; S. C. Busey, of District of Columbia; T. J. Gallaher, of Pennsylvania; C. Deveny, of Illinois; W. W. Johnson, of District of Columbia; A. M. Pollock, of Pennsylvania; J. S. Billings, U. S. A.; C. E. Vaughn, of Massachusetts; H. O. Marcy, of Massachusetts; J. V. Shoemaker, of Pennsylvania; E. C. Harwood, of New York; H. P. C. Wilson, of Maryland; J. C. Hutchison, of New York; J. F. Gabriel, of Virginia; S. C. Gordon, of Maine; T. L. Estabrook, of Maine; G. T. Stevens, of New York; S. J. Jones, of Illinois; E. M. Dent and Joseph Parrish, of New Jersey; Edward Boeck, of Missouri; Christopher Johnston, of Maryland; J. N. Quimby, of New Jersey; and Austin Flint, Sr., of New York.

THE DEATH OF DR. J. MARION SIMS.

A resolution offered to express the regret of the Association for the death of Dr. J. Marion Sims, and the sense of their loss, was unanimously adopted.

A MONUMENT TO BENJAMIN RUSH.

DR. GIHON called attention to the fact that among all the monuments to the memory of great men for which Washington is noted, there is not one to the memory of a physician. He, therefore, moved that the Association signalize its meeting in this city by providing for the erection of a statue of the eminent Dr. Rush, who was a member of the Continental Congress, a signer of the Declaration of Independence, and intimately associated in various ways with the early history of this country. He further asked that a committee of seven be appointed to consider the advisability of the project. Adopted.

RESOLUTIONS OF THANKS.

DR. BRODIE moved a vote of thanks to the Committee of Arrangements, and other committees, and to the ladies and gentlemen who have given receptions and done so much in various ways to make pleasant the stay of the Association in Washington.

DR. GARCELON, of Maine, moved that the Association return its sincere and heartfelt thanks to the retiring president for the graceful and efficient manner in which he had conducted the proceedings of the session.

DR. FLINT, in response, thanked the Association for the forbearance and coöperation he had received in his attempts to perform the duties of a presiding officer. He also congratulated the Association on the fact that the present had been the largest meeting ever held; on the amount and quality of sectional work that was done, and on the interest and ableness of the discussions in the Sections. "I therefore wish," he said, "the members a safe return home, and a continuance of life and of every happiness."

The Association then adjourned to meet in New Orleans the last Tuesday of April, 1885.

SECTIONS.

SECTION ON PRACTICE OF MEDICINE.

WEDNESDAY, MAY 7TH—SECOND DAY.

DR. R. HARVEY REED, of Ohio, read a paper on

IRRITATION OF THE CAPSULE OF GLISSON.

This is a periodical affection located in the liver or capsule, affecting the tunic of the liver and penetrating to the lobules of the organ, and often partakes of a rheumatic character. It is characterized by darting pains of a burning or boring character, coming on usually at night. It is not ushered in by a chill, nor is it accompanied by febrile disturbance, loss of appetite, headache, or constipation. It occurs sufficiently often to merit special attention, as Dr. Craig, of Ohio, says he has seen five cases in a year, and the author has observed it twenty-five times in six years. The affection generally attacks those who follow sedentary occupations, and is more frequently observed in women. It is a disease of middle life, is more frequent in those not addicted to alcoholic stimulants, and is often associated with rheumatism. Its onset is often insidious, the patient feeling, at times, slight pain in the hepatic region, to which he pays but little attention. With each return, however, the attacks become more severe and the intervals shorter. The history of a paroxysm would be somewhat as follows: The patient goes to bed well, is awakened by severe pain of the character above described, which in the less advanced stages of the disease will subside by morning, leaving the patient as well as usual. With each return the severity as well as the duration of the attack increases, and it sometimes lasts for several days. The pain is confined to the hepatic region, and is burning, boring, and lancinating in character. The tongue may be somewhat furred,

and there is sometimes vomiting, but there is no increase in the temperature, nor is there headache or jaundice. There is slight tenderness on pressure over the liver, it is not perceptibly harder, there is no change in the size of the organ, and no sign of hob-nail liver. The stools contain no gall-stones, and the urine is normal. In the later stages of the disease there may be a certain amount of emaciation. This disease must be differentiated from hepatic colic, interstitial hepatitis, congestion of the liver, perihepatitis, cirrhosis, and hepatalgia. Hepatic colic is excluded by the gradual onset and increase of the disease, by the occurrence of the attacks at night, whilst in hepatic colic they may occur at any time, especially after meals or exercise. The vomiting which so frequently accompanies the colic is generally absent. The absence of jaundice and failure to discover gall-stones in the stools complete the differential diagnosis. *Interstitial hepatitis* is differentiated from irritation of the capsule by its connection with alcoholic excesses; by the appearance of venous stigmata on the cheeks, etc.; by the presence of jaundice; the pain over the liver is constant instead of intermittent; there are nausea and vomiting on rising, and the loathing of solid food; diarrhœa alternates with constipation, and the urine is scanty; there is occasional pyrexia, and there is obstruction to the portal circulation, and enlargement of the liver, followed by contraction; there is often ascites, and a dry, harsh skin. Besides this, interstitial hepatitis is often the result of syphilis, while irritability of the capsule seldom is. In *congestion of the liver* there are enlargement, a continued sense of tightness in the hepatic region, jaundice, nausea, anorexia, furred tongue, headache, disturbances of digestion, vomiting, diarrhœa, dyspnœa, drowsiness, signs of portal obstruction, urine scanty and high-colored, temporary albuminuria. The attack continues without interruption. In *perihepatitis* there is peritonitis, and the inflammation may extend to the capsule of Glisson. It may arise from traumatic causes. It is ushered in with a chill, followed by fever, and there is much superficial tenderness.

Inflammation of the bile ducts occurs mostly in children and old persons. There is obstruction to the entrance of bile into the duodenum—jaundice; it is preceded by gastro-intestinal catarrh, the pulse is slow, and there is no bile in the stools; while in irritation of the capsule, the stools are normal. *Cirrhosis of the liver* can be readily differentiated by its history and signs. *Hepatalgia* is extremely rare, and occurs only in nervous women, being a purely functional disease. Irritation of the capsule may continue for years, and, if left to itself, has no inherent tendency towards recovery, but the prognosis as regards life is good. There are few diseases which yield more quickly to well-directed treatment. The author relies mostly on alkalies and bitter tonics—his favorite combination being bicarbonate of soda with pulv. hydrastis canadensis. Sodæ et potass. tart. and infusion of gentian are often serviceable. Mercurials are seldom useful. It should be remembered that it may be complicated by rheumatism, malaria, and disease of the liver, which must, of course, affect the treatment. Stimulants and condiments are to be avoided, regular habits enjoined, and active exercise according to the patient's strength advised. Baths containing chloride of sodium, conjoined with rubbing, are beneficial. During the attack, morphia may be used hypodermatically, and local application of heat affords relief. Anodyne treatment should be suspended as soon as possible.

DR. WILLIAM PEPPER, of Philadelphia, then read

A CONTRIBUTION TO THE CLINICAL STUDY OF EPILEPSY.

He said that our conception of epilepsy is necessarily broad and somewhat vague. It would be well to exclude, if it were possible, from the category of the affections grouped under this name, all cases in which there are definite anatomical lesions, but while this can be done in certain cases, *e. g.*, where there is a cerebral tumor, it is often impossible, and probably a large number of cases of so-called epilepsy are really associated with some anatomical lesion. He referred to a case of a physician who was forty-four years old when he died. When he was twenty-three years old he had received a severe injury to his head, which was followed by convulsions. He recovered and engaged in active practice. After eighteen years he had a convulsion following a period of over-work. After this, convulsions returned every four to six weeks without any cerebral symptoms. Bromides failed to produce any effect, but temporary recovery followed the use of the actual cautery and rest. A relapse occurred on returning to work; trephining was resorted to, and a depression of the internal table of the skull was found and raised; a spicule of bone was found pressing on the brain, in which were two small abscesses. These were certainly caused by the injury eighteen years before. Besides the difficulty of excluding anatomical lesions, it is sometimes hard to exclude hysteria, and the two conditions are sometimes combined.

One of the fundamental elements in the production of epilepsy is morbid instability of nerve tissue. Heredity has a marked effect, and so has nervous exhaustion from rapid growth or after severe diseases, as typhoid fever and scarlatina. A very frequent cause is shock, whether psychical, or from mechanical injuries, or, and this very frequently, sunstroke. Instability of the circulation through the brain is an important factor, as are also anæmia and cardiac disease; so also, prolonged peripheral irritation, as in protracted teething, undue sexual excitement, and intestinal irritations. Epilepsy is then not a distinct disease, but results from morbid instability and irritability in the gray matter of the encephalon. There are cases which are marked by progressive molecular changes, and more or less regular manifestations, but this is uncommon. The evil effect of habit is often seen in this disease, and unless the tendency is avoided, the attacks become more frequent. Sometimes the slightest cause is sufficient to bring on an attack, such as a noise or an indiscretion in diet—this last is a frequent cause, by impairing nutrition and lessening the stability of the nerve tissue, either by reflex action or by the blood being poisoned by the products of malassimilation.

It is not infrequently associated with lithæmia. It often follows scarlatina, either from exhaustion from the disease, of widespread tissue changes, or by inducing renal changes, which, while not sufficient to show the existence of albumen, are sufficient to cause a certain amount of toxæmia. Dr. Pepper called attention to the frequency of the prodromic signs which occur in epi-

lepsy, such as loss of appetite, pains in various parts of the body, changes in the appearance of the face, foul breath, digestive disturbances, and dwelt upon the effect of excitement in the production of the attacks, whether the excitement be from sexual intercourse or alcohol, from intellectual over-work (especially noted when there was competition, as in examinations), or from anxiety. Over-work or severe strain, especially when connected with cardiac disease, excessive heat, brilliant sunshine, bad air, all conduce to bring on an attack in those who are subject to epilepsy. It rarely happens that epileptics are in really good health.

In regard to the treatment, Prof. Pepper thought that while the bromides were of incalculable benefit, they had been used too much as matters of routine treatment, and had led to the overlooking of the still more important subjects of attention to dietetics and hygiene, and the administration of medicines on general principles. The bromides control, but do not cure epilepsy. The peculiarity of each case must be studied, and a suitable regimen must be inaugurated, and the primary, underlying, or provoking causes must be searched out and treated on general principles. Thus, lithæmia and anæmia must be met with appropriate medication, and very often it will be found that prolonged rest is most serviceable. This is especially the case where there is cardiac involvement. In these last cases, also, digitalis is often found useful. So also gastro-intestinal irritation must be treated when present. In these cases, silver nitrate, zinc, or arsenic is valuable. Where there is any local irritation it must be removed. Counter-irritation, as by actual cautery to the spine, is most useful, especially where there seems to be cranial involvement. It is specially useful in cases caused by sunstroke. Trephining should be done oftener than it is. The influence of adherent prepuce has been somewhat overestimated. Pure milk diet is often useful.

During the attack nitrite of amyl is most helpful, and is important for the breaking up of the habit. Returning to the bromides, he thought they often injured by irritating the stomach. He used them in the smallest dose that would have the desired effect. He had often seen enemas of chloral hydrate act admirably. This mode of administration is specially indicated in cases in which there is irritability of the stomach.

Prof. Austin Flint, of New York, in opening the discussion, presented

AN ARGUMENT FOR THE TOXICAL PATHOLOGY OF EPILEPSY.

He did not consider this out of place in this discussion; the treatment must, in the end, depend upon pathology. There is at present an absence of any distinct pathological doctrine on epilepsy. It has no established anatomical character. It is essentially a neurosis, without known causative conditions. There are no distinct prodromata to the attacks; the aura is mostly wanting, and has no special significance. The various theories maintained by Hughlings Jackson and others do not really furnish explanations of the disease. The field, then, is comparatively clear of old theories to be taken out of the way. There is a close analogy between epilepsy and states of the system produced by toxical agents, as uræmic convulsions. It is now generally accepted that these convulsions are caused by retained substances in the blood that should have been excreted by the kidney. But he remembered the time when the pathology of uræmic convulsions was as much a mystery as that of epilepsy is now. Sometimes uræmic coma, etc., simulate epilepsy so completely as to require an analysis of the urine to make a differential diagnosis; and again, when the epileptic attack is of long duration it may simulate the uræmic condition. This would seem to show that the pathology of epilepsy is toxical. The clinical history, the absence of ailments prior to the attack, the short duration and quick recovery, seem to point to the effect of a transient poison in the production of the seizures. This does not exclude, however, the effect of local conditions. Pathology has not yet given successful direction to the therapeutics of epilepsy. The more recent remedies introduced seem not to be curative, but to enable the nervous centres to tolerate the presence of the poison.

The *modus operandi* of the poison, as well as its nature and source, remains to be discovered. Then, when these are found out, we shall be able, with more hope of success, to discuss how to prevent the formation of the poison, neutralize its effects, and eliminate it from the system.

Dr. Eugene Grissom, of North Carolina, had seen a large number of cases of epilepsy, but they have generally been at an advanced stage of the disease. He considered it as often an organic affection, and it is usually inherited. It is generally preceded by eclamptic attacks during childhood, and shows itself about the age of puberty. It may represent chorea, or some wasting disease in the parent. It may occur in the offspring of syphilitic or scrofulous parents. It may be the last development in a long course of family degeneration, as in the royal house of Spain. No course of treatment can in one lifetime restore the injuries of generations. It is caused by innutrition of the nerve centres as opposed to malnutrition. The circulation itself is disordered, and the stimuli given to restore the organism to its normal condition may be transformed into excitants. When the disease is functional it is more hopeful. It is the more frequent form, and is protean in its manifestations. It is induced (1) by draughts on the vital powers of any kind; (2) irritation of the peripheral trunks. It is apt to expend its power chiefly on the most used muscles of voluntary motion. It is often associated with anæmia. The treatment calls for regular, systematic, but unfatiguing, exercise; for influences that will build up and develop the *whole man*. Special complications demand treatment adapted to these conditions. He recommended preparations of zinc when there seemed to be pneumogastric irritation.

Dr. James F. Hibberd, of Indiana, doubted the advisability of always administering drugs. Excluding cases in which one can recognize the existence of an exciting cause, he did not believe that epilepsy could be cured. Medicine, at most, will only arrest its manifestations for a time. Every individual has his own standard of health. When that is reached, all remedies should be stopped. He believes there is such a thing as a convulsive diathesis. Individuals who suffer from it will have epileptic seizures from causes that might produce only headache in an ordinary person.

Dr. J. J. Caldwell, of Maryland, doubted whether cases lasting for years could be of toxæmic origin.

DR. JAMES TYSON, of Philadelphia, recommended the use of a seton through the nape of the neck. He had known one case in which it was tried fifteen years ago, and there has been no relapse since.

DR. E. M. BARTLETT, of New York, also recommended setons, and united in Dr. Pepper's warning against the indiscriminate use of bromides.

DR. BALTEEN, of Massachusetts, had great faith in the use of bromides, but would vary the salt in different cases, using potassium bromide in plethoric cases, sodium and iron bromides in anæmic, and lithia bromides in gouty cases. He had seen good effects from physical influences, such as causing patients to use the spirometer, the peculiar noise seeming to affect their minds. He used wine of ipecac, five drops every three hours, in cases of disordered stomach.

DR. PEPPER, in closing the discussion, agreed with Dr. Flint in referring certain cases to a toxic origin, but did not consider that this explained all the cases. It is important to remember that the generation within the system of the products of malassimilation is capable of producing convulsions. He would reassert the supreme importance of attention to dietetics and hygiene, without which no drug is of any avail.

DR. J. C. WILSON, of Philadelphia, then read a paper on the

DIAGNOSIS OF TUMORS OF THE ANTERIOR MEDIASTINUM.

He described this region as a physiological and anatomical "no-man's land," of very slight importance in health, but pathologically of great importance, and often neglected. The distinction which should be made between growths in the posterior and anterior mediastinum, for scientific diagnosis and treatment, is often overlooked. Disease is found in this locality in two forms: First, purulent inflammation of the tissues; second, new growths. Simple acute inflammation is unknown. There is one case on record of inflammation resulting in a solid exudation. Abscess, on the other hand, is not uncommon. The growths are divided into cysts (generally dermoid, and very rare), lipomata, fibromata, and osteomata, exostoses, tubercular disease in the glands, gummata and lymphoma, carcinoma, and sarcoma. Tubercular disease in the glands of the mediastinum is less frequent than in the bronchial glands and cannot be diagnosticated. The first mentioned of the above varieties are very rare; the last three are the most common. Carcinoma is always secondary in this locality, and primary sarcoma is rare. Lymphoma is the commonest form. It occurs in the glands, and rapidly involves the surrounding structures. It must attain a sufficient volume to press on the neighboring organs to be discovered. It is to be diagnosticated from aortic aneurism and tumors in the posterior mediastinum. Physical signs merely reveal the presence of a tumor, but do not show its special character. The symptoms are: pain of a superficial character, dyspnœa, scanty expectoration, and dysphagia, with paroxysmal intensification of the symptoms. There is no fever; nutrition is good, except when the œsophagus is pressed upon. Among the signs are: Repletion of veins of the face, prominence of eyes, livid lips, arborescent condition of varicose veins upon the chest, enlargement of the chest above the fourth rib, enlargement of the thymus gland, when present, and of glands in the axillæ, asymmetrical expansion of the chest on pressure, displacement of the heart, increased dulness over the upper part of the sternum corresponding to the size of the tumor, and dulness in the interscapular region, if the growth be large. The auscultation signs are somewhat modified. Cardiac sounds are feeble, though sometimes intensified over extra-precordial region over the tumor. There is no stridulous breathing, but enfeeblement of the respiratory murmur, if a bronchus of one side be obstructed. *The enlargement of the veins* distinguishes it from tumor of posterior mediastinum. Aneurism is excluded by the history, by the absence of thrill, by the early age at which the disease occurs, and by the stitch-like, superficial character of the pain. Pericardial effusion is excluded by the irregular outline of dulness, by its higher level, absence of fever, and by the history and progress of the case. Excision of the sternum has been resorted to with some success. The existence of malignant disease in other parts of the body is a great help in the diagnosis. Abscess may occur from blows, caries, or operations in the vicinity. There will be constitutional symptoms: Chill, fever, deep-seated pain, and pointing of the abscess. The paper concluded with some remarks on the rarer forms of disease in this locality.

DR. WM. H. WELCH, of New York, then read a paper on the

PATHOLOGY OF MYOCARDITIS.

The neglect of this disease by practitioners is caused partly by the difficulty of diagnosis and partly by absence of proper descriptions in the text-books. It is far more important than fatty degeneration, which generally receives a great share of attention, and many of the supposed symptoms of the latter are really due to disease of the coronary arteries. Many autopsies after sudden death, have shown the only appreciable cause to be lesions of these vessels. Myocarditis may be acute or chronic. The acute may be of a parenchymatous or interstitial type. The parenchymatous is a degeneration of tissue, and not properly an inflammation. The interstitial form may occur either as an abscess of the heart or as a non-suppurative inflammation. It may be circumscribed or diffuse. It may occur in the course of diphtheria or the acute infectious diseases. It is important to observe that *this disease occurs very often without the coexistence of either pericarditis or endocarditis*. The view that it is secondary to either of these diseases is incorrect. Fibroid myocarditis is generally associated with obstructive lesions of the coronary arteries, and may be caused by sclerosis or obliteration of the arteries or by thrombosis or embolism. Inflammation does not come first, but degeneration and atrophy. The disease is not referable to syphilis or chronic Bright's disease, and often attacks patients in well-to-do circumstances. He had made autopsies of myocarditis which may be clinically grouped as follows: *First*, where there was no symptom of heart disease. *Second*, sudden death without previous heart symptoms. *Third*, sudden death preceded by one or more attacks of angina pectoris. *Fourth*, with cardiac insufficiency of few days' standing. *Fifth*, in cases of old cardiac disease.

DR. FLINT, of New York, said that the cardiac symptoms and signs of this disease are purely negative—an

autopsy after sudden death alone revealing the existence of disease in the coronary arteries. In cases which we would diagnose as functional disease of the heart, it is well to make a mental reservation as to the possible existence of these lesions which might cause sudden death; but in such cases the chances are so strong that the disease is not present, and the importance of encouraging the patient so great, that it is wiser not to state our apprehensions.

Dr. Frank Donaldson, of Baltimore, thought we might at least suspect the presence of the disease by the weakness of the cardiac impulse, by the sphygmograph, and by the existence of disease in other arteries.

Dr. Gaspar Griswold, of New York, then read a paper on

IRREGULAR APOPLECTIC ATTACKS FROM OTHER CAUSES THAN HEMORRHAGES OR EMBOLISM.

The paper contained records of cases in which patients had been attacked with all the symptoms of apoplexy, so as to deceive the attending physician into giving a grave prognosis, but recovered rapidly without any after ill effects. So closely was apoplexy simulated, that in a number of these cases there was not only unconsciousness, but transient hemiplegia. The author considered that the cause of the apoplectic attack in cases of hemorrhage or embolus, is a disturbance of the intracranial circulation. In cases of functional disorder, the same effect is temporarily produced, and therefore, at first sight, it is difficult to distinguish between them. He considered that cerebral anæmia was more frequently the cause than cerebral hyperæmia. The exciting cause may be prolonged anxiety, as in business matters, indiscretions in diet, etc. It is sometimes preceded by anæmia. The various cases were related in detail. The differential diagnosis is to be made by the short duration of the case. The only exception to this is in cases in which there is inequality of the pupils. This phenomenon Dr. Griswold considered to be proof positive of genuine apoplexy.

Dr. E. G. Janeway, of New York, spoke of two similar cases which had been brought on by excessive smoking. On leaving off the use of tobacco there was no further return of the attack.

Dr. Austin Flint, Jr., of New York, spoke of the importance of the cerebral circulation in its influence on the symptoms in these cases. Loss of blood produces convulsions from the extreme exaggeration of the *besoin de respirer*. From his own experiments he thought this due to the cutting off of arterial blood from the medulla oblongata.

THURSDAY, MAY 8—THIRD DAY.

Dr. Austin Flint, Jr., of New York, read a paper entitled

THE DIETETIC TREATMENT OF DIABETES MELLITUS.

He said that it occasionally happens that the presence of sugar is detected in persons who seem to be in thoroughly good health, though this is very rare. From an extensive experience in examining for life insurance, he would estimate that it occurs in one person out of every three hundred and seventy-seven persons. In most cases attention is called to the trouble by the symptoms. There are thirst, polyuria, dryness of the feces and of the skin, weariness on exertion, etc. Pruritus of the vulva is an extremely common occurrence, and, when not explicable otherwise, should always lead to an examination of the urine. The usual symptoms, however, are not always all present by any means. As to the detection of sugar in the urine, which is, of course, *the sign* of the disease, he said that the great desideratum has been a test that would be simple and easy and yet accurate. Fehling's test when accurately used is certain, but it is apt to become inoperative when the solution is kept for a long time. He considered that two liquids which had been prepared by Squibb, of New York, answered every requirement. Without taking the time to describe them fully, he gave the method by which they should be used. Mix equal parts of the two fluids and pour the mixture into a test-tube to the depth of an inch. Bring it to a boil. Then add an equal part of urine and bring the mixture thus made to a boil. Then allow it to cool. These steps are most important to be observed. If on cooling there is no distinct opaque yellowish or reddish precipitate, there is no sugar. The promptness and amount of precipitate indicate aproximatively the amount of sugar. For the more accurate determination of this, the differential density method of Roberts is good. The specific gravity of urine has no definite relation to the amount of sugar. Owing to the proportion of urea, diabetic urine may have a specific gravity as low as 1011. Normal quantity and specific gravity of urine do not *exclude* the existence of diabetes.

The author then touched upon the symptoms, etc., of the disease, and to some extent upon the glycogenic function of the liver. In this connection, he said that he thought his own experiments had harmonized with those of Bernard and Pavy. He believed that sugar was formed in the liver, but was very rapidly washed out of the organ by the blood current. The discovery of Bernard, however, had not thrown the light upon the etiology of diabetes that had been hoped at first. Besides the sugar from the liver, we have the sugar resulting from digestion. In diabetes much of this is discharged through the kidneys. The failure of the body to consume the hydrocarbons results in a loss of heat. The temperature is below normal. He spoke of a patient of his whose temperature is 96.5° F. How far can diabetes mellitus be treated? Cantani says, "Diabetes has become a disease *easily and certainly curable*, if treatment be not begun too late." Dr. Flint did not think this statement extravagant when we consider the results of the dietetic treatment, provided it be submitted to. A cure is the result or, at least, a removal of the symptoms, except an occasional slight glycosuria. Our main reliance is upon diet, which must be one that *absolutely excludes starch and sugar*. This is difficult to enforce. There is often a craving for starchy food, especially bread. There are numerous so-called antidiabetic breads, which are said to contain no starch. Dr. Flint has had many of them analyzed. They are all frauds, sometimes containing more starch than ordinary bread. If the patient will not submit to the diet, he may be allowed a piece of the crust of a roll with plenty of butter twice a day, under protest. The craving for starchy food and for sugar diminishes. It is difficult to make a diet-table of foods that do not contain these ingredients, but it can be done, especially if

the patient be in well-to-do circumstances, and he may live even luxuriously. Even in mild cases this rigid regimen must be kept up for at least two months. Then a gradual return to usual diet may be allowed, the urine being examined every five days, and the strict diet at once enforced if any sugar be found. As regards general treatment, the action of the skin must be excited, general untiring exercise, a mild course of training, massage, Turkish or Russian baths, may all be tried in cases in which they are not contraindicated. The patient must not drink much. The anti-diabetic diet will lessen the thirst. The sucking of cracked ice is good. Alcoholic drinks are injurious and should be avoided, especially champagne and spirits are to be interdicted. If something of the kind must be taken, claret in small quantities is the best. The patient cannot bear sustained effort, and all causes of mental anxiety must be avoided. As a rule, the insomnia does not require narcotics. When boils appear, sulphide of calcium is of great benefit, though it does not affect the disease itself much. The lowered temperature of the body makes great care necessary to avoid taking cold.

The medicine which he recommended chiefly, was Clement's solution of the arsenite of bromine, in three-drop doses three times a day in a wine-glassful of water (two drops represent one-twenty-fourth of a grain of the salt). The system can tolerate this drug for months. But no drug will be of use without diet. Patients should be informed that they are suffering from a serious disease and must follow directions. There is always danger of a relapse.

DR. H. F. FORMAD, of Penna., then read a paper on

TUBERCULOSIS.

The author regretted that his remarks on this occasion had to precede the publication of investigations which he had recently undertaken in the laboratory of the University of Pennsylvania. These investigations will soon be published, with full details of the methods adopted, etc., and will substantiate the views he was about to announce. He hoped the Section would understand that he did not regard the question as a personal one; he wished to learn, and would take any objections in good part.

The recent advances in mycology have received great attention among investigators, especially the discoveries of Koch in regard to the tubercle bacillus. These are of great importance and demand close consideration. He would divide the subject into three headings: (1) The contagiousness of tuberculosis; (2) a brief definition of Koch's present position; (3) objections to Koch's theories—which objections remain unanswered.

(1) *Contagiousness.* This is a most important question, clinically and socially. Besides this, the acceptance of the bacillus theory hangs upon the contagiousness of tuberculosis. If the disease be not contagious, the parasitic theory of the disease falls to the ground. There is no satisfactory clinical evidence of the contagiousness of the disease. The cases that have been reported in which the wife or the husband contracted phthisis after nursing the partner who had consumption are only seeming exceptions, for scrofulosis may be acquired by unhealthy surroundings. Besides this, the great prevalence of consumption makes it necessary to show that the individuals who are said to have been infected were not by inheritance predisposed to the disease. The theory that children become scrofulous by contagion from phthisical parents is untenable, for they will become scrofulous even if they are taken from their parents. The investigation made under the auspices of the British Medical Association, showed that out of 1028 cases of consumption 623 furnished no evidence of contagion, and only 261 seemed to be in favor, but among these the causes of error (family history, surroundings, etc.) were not eliminated. Isolated instances of apparent contagion cannot be placed against the thousands of cases of the closest intimacy between the diseased and the well, without any spread of the complaint whatever. The experiment has been tried of direct inoculability of the disease in man. There is a celebrated case in which a man already half dead was inoculated. He died in three weeks. Laennec inoculated himself, and *twenty years afterward* died of tuberculosis—and this is cited in support of the contagion theory! Bearing on this we have experiments, in Würzburg, where the sale of tuberculous meat is not prohibited. Whole families were fed on the infected meat—often using it raw. They were under supervision for many years. Yet in no case did consumption occur—in fact they throve on the diet.

Neither is there analogy between tuberculosis and other contagious diseases. If we claim immunity from the latter, we know how it comes, either from a previous attack of the same disease, as in scarlatina, etc., or from other processes (as in vaccination). This is not the case with tuberculosis. If there is immunity, it is in the system. Predisposition also is constitutional, as can be proved both by macroscopical and microscopical appearances in the scrofulous child. Beside congenital predisposition, there may be an acquired predisposition. This may be brought about by unhygienic surroundings, etc. Tuberculosis also may be acquired by injuries of the serous membranes even without external openings, as in pleurisy, etc. Cohnheim gave a fresh impetus to the theory of contagion. He succeeded in inducing tuberculosis by injecting tuberculous matter into the eye, while innocuous substances did not produce the disease. In publishing these experiments, he slurred over his former experiments with innocuous substances in the peritoneum which had produced tuberculosis.

(2) *Koch's Theory.* Koch has proved that in all tuberculous deposits, whether in the lung or in organs secondarily affected, the tubercle bacillus is found, and that this bacillus is not found elsewhere. He says the bacillus is chiefly found in the youngest tuberculous deposits. He then by his culture methods isolated the bacillus, and with the bacillus obtained by culture he inoculated healthy animals and produced tuberculosis and found the bacillus present. He inoculated other animals from these, and again produced tuberculosis. This bacillus only thrives in animal substances and at the temperature of the body. From these facts he concludes that this bacillus has the same causative relation to tuberculosis that anthrax bacillus has to splenic fever. If all he claims is true, he has satisfied the scientific requirements of the case. But while his facts are true, his conclusions are faulty. Koch the mycologist is right, but Koch the pathologist is in error. The evidence is not yet all in, and we must pause before we accept his teaching.

(3) *Objections to Koch's Theory.* These are not personal in any sense. The etiological relation between the bacillus and tuberculosis is not evident, because the bacillus, while usually present, is not found in all cases, and sometimes when it is found there may be only one or two bacilli in one section; that is, they are not in sufficient quantity to be considered causative. Again, the weight of evidence, and with this Dr. Formad's experiments agree, is that they are most frequently found in old cases and are not so often present in the beginning of the process—in fact, are often absent. But if Koch is right, the bacillus should be present in all cases, especially in the early stages. The truth is, the bacillus is a mere concomitant of degenerated cheesy materials. Even Koch allows that pus without the presence of the bacillus when inoculated from tuberculous deposits may cause tuberculosis, but he suggests the existence of spores. This is a mere assumption which can neither be proved nor disproved. May it not be true that the cheesy deposits furnish a suitable soil for the bacillus to grow upon, and that without this soil they will not grow?

It has not been proved that the disease as produced in the lower animals is identical with the disease in man, although the bacillus in both may be the same. The lesions are not always tubercular. Those resulting from the inhalation-experiments, which showed the presence of miliary nodes in the lungs, have been shown to be merely foci of catarrhal pneumonia. The nodes are simply inflammatory products which can be wiped out with a camel's hair-brush, leaving healthy lung. Some of Koch's experiments are of the same character. They only relate, at any rate, to rapidly produced tuberculosis. If sufficient time be allowed, any substance will produce the disease in animals predisposed to it. Again, experiments on animals cannot be made to prove anything in regard to man, nor can the effect of an experiment on one animal be predicated from its effect on other animals.

We are too apt to forget that the question is not whether the bacillus produces tuberculosis, but whether other and innocuous substances can produce it. Koch's proof-experiments in this direction are valueless. As there is good evidence that the disease can be produced by innocuous substances, it is not fair to assume that the bacillus must have entered somehow. Tuberculosis may exist without the bacillus, and *vice versâ*. Either, then, Koch is wrong on anatomico-pathological grounds, or tuberculosis must be reclassified into that with and that without the bacillus.

In conclusion, neither the specific action of the bacillus nor of tuberculosis is proved. The bacillus is valuable in diagnosis, but it has no bearing upon the etiology of the disease. On social grounds, the acceptance of the bacillus theory would be disastrous. There is a poison in tuberculosis, but it is generated by the body itself. Tuberculosis bears an analogy to carcinoma from a pathological point of view.

Dr. Austin Flint, of New York, said that the contagiousness of phthisis is a side issue. If tuberculosis be caused by a parasite, it is contagious, and clinical facts must be explained in accordance with this view. The question is: 1. Is there a parasite? Yes. 2. Is it uniformly present? The burden of testimony goes to show that it is, so that the exceptions may almost be put down to the want of skill in the observer, or some accidental cause. 3. Is the bacillus found in morbid products, not tuberculous? As a rule, no. 4. Can tuberculosis be produced by this parasite alone in the lower animals? Yes. Dr. Formad assumes that the disease may involve a parasite, but not be due to the parasite. This is opposed to the general laws observed in parasitic disease. If a parasite be proved to bear a causative relation to tuberculosis, it must be the cause *par excellence*, though predisposing causes may exist, and help.

Dr. Welch, of New York, said that the necessary proofs for the bacillus theory of tuberculosis are forthcoming. The bacillus is almost constantly present in the disease. It has been isolated, and has produced tuberculosis, and inoculation with other substances does not produce it. When Koch first published his discovery, reports of cases in which the bacillus was absent were frequent. They are now becoming more and more rare, as the skill of the operators is improving. All observers admit that it is present as a rule.

He defended Cohnheim's experiments on the eye, referred to by Dr. Formad, and said that, so far from slurring over his experiments on the peritoneum, Cohnheim repeated them with greater precautions, and found them unsuccessful. Is it certain that the lesions produced by innocuous substances are really tubercular. To prove them so, they must contain the bacilli, and be able to convey the disease. This is not, he said, a *petitio principii*, as the presence of the bacillus in tuberculosis is proved. So far from the parasite not being present in recent cases, it is most frequently present in such lesions.

Dr. George M. Sternberg, U. S. A., was inclined to think that the bacilli might act as the carriers of infection. They needed a tubercular soil. Dr. Formad's theory of their acting as irritants is worthy of consideration. He would like to know whether the bacilli were found in cases in which innocuous substances had produced the disease, and had the disease the same history as when caused by inoculation with the bacillus. He thought the bacillus necessary to cause cheesy degeneration and auto-infection. In regard to Dr. Formad's experiments, if they were really carried on with all possible precautions, and the animals experimented upon kept isolated, then the bacillus is not the only cause of tuberculosis. He had doubts, also, as to whether Koch's method of cultivating the parasite upon the surface of the culture-material was likely to produce a perfectly pure bacillus.

Dr. R. H. Fitz, of Massachusetts, said that Koch's view is, that the inflammations themselves are the result of the bacillus. In regard to Dr. Formad's experiment with innocuous substances, there must have been some error. The air of pathological laboratories is full of bacilli.

Dr. James Tyson, of Pennsylvania, was disappointed that Dr. Formad had not given his experiments to the Section. He was yielding more and more to the accumulating evidence in favor of the bacillus, and referred particularly to the experiments of Fischer, published in Koch's last report, in which sterilized and non-sterilized tuberculous sputum was used, the former causing tuberculosis when inoculated, the latter not. He did not think that tuberculosis must, therefore, be contagious. It may be infectious, as malarial fever is.

Dr. Janeway, of New York, agreed with Dr. Welch.

In respect to contagiousness, he did not think that the clinical side of the question should be discarded. His clinical experience had induced him to believe in the contagiousness of the disease. This, so far from being a social injury, will be a social benefit, as preventive measures can be taken. He detailed several cases to prove his point. Among others, he mentioned the case of three dogs who were petted in succession by a tuberculous master, who took them to bed with him, and all of them died with symptoms of phthisis.

DR. CHARLES DENNISON, of Colorado, spoke of the analogy between tuberculosis and fibroid condition of the lung and also croupous pneumonia. The distribution geographically of croupous pneumonia and consumption is very nearly alike. He showed four carefully prepared maps of the United States, on which the relative dampness, etc., of the various sections were diagramatically represented by various colors. He divided the country into regions of (1) excessive dryness, (2) moderate dryness, (3) excessive moisture, (4) and moderate moisture. The four maps represented the state of different parts of the country during the four seasons. He considered that the infectious principle is favored by dampness and heat, and that dryness and cold are inimical to it. This is the reason why elevation is so good for phthisis.

DR. E. O. SHAKESPEARE, of Philadelphia, summed up the proofs in favor of the microörganism of tuberculosis as causing the disease, and criticised Dr. Formad's method of investigation and the precautions he used, thinking that his conclusions were not well founded.

DR. G. C. SMYTHE called attention to the varieties of infectious diseases. The first are purely contagious, as smallpox; the second are infectious not directly, but the germ must come to maturity outside of the body, as in typhoid fever; the third are miasmatic, as malaria. If we assume that all infectious diseases are the result of microörganisms, which act as specific poisons or as carriers, a predisposition on the part of the individual is still necessary. Some families show great susceptibility to certain diseases, *e.g.*, diphtheria. Perhaps tuberculosis might be classified with the local contagious diseases, as syphilis, leprosy, etc., commencing at a certain focus, and thence infecting the whole body. He thought Dr. Formad admitted too much for his own argument.

DR. HAROLD C. ERNST, of Mass., spoke of the various methods of staining the bacillus. He condemned Gibbs's method, and thought Frænkel's only partially satisfactory, but praised Koch's last method, and Ehrlich's.

DR. WILLIAM PEPPER, of Penna., had paid much attention to the literature of the subject, and held his judgment in suspense. In regard to the character of Dr. Formad's address, he was largely responsible for it, as he advised him not to give an account of his recent unpublished experiments. Dr. Pepper wished to lay stress upon the carefulness and conscientiousness of Dr. Formad's work. His personal knowledge of this gave him the right to speak thus in answer to Dr. Formad's criticisers. He was sorry so little original work has been done in this country in this direction. He thought clinical evidence was an important part of the question. His experience had been positively in favor of the non-contagious character of tuberculosis.

DR. TRAILL GREEN, of Penna., spoke strongly in favor of the non-contagious character of phthisis from a clinical experience of half a century.

DR. TILLEY, of Illinois, thought the chemical side of the question had been lost sight of. The chemical character of the soil the bacillus grows on should be carefully studied.

DR. FORMAD thought that Koch had not made out his case fully, and that it brought others into misconceptions to rely upon his statements. He said that he had taken especial pains to avoid error. His animals were better cared for, and in purer air than Koch's. Those animals experimented upon with innocuous substances are taken to the country.

The Section then adjourned.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Sixth Annual Congress, held in New York, May 12, 13, and 14, 1884.

(Specially reported for THE MEDICAL NEWS.)

MONDAY, MAY 12TH—FIRST DAY—MORNING SESSION.

THE PRESIDENT, DR. FRANCKE H. BOSWORTH, of New York, delivered an address of welcome, and afterwards read a paper on

THE CLINICAL SIGNIFICANCE OF FIBRINOUS EXUDATIONS UPON THE MUCOUS MEMBRANE OF THE UPPER AIR-PASSAGES.

Among his conclusions were the following:

That a fibrinous exudation which occurred on the crypts of the follicles of the faucial or pharyngeal tonsil, or of the mucous membrane of the lower pharynx, had no tendency to extend, and belonged to a disease which was self-limited, and not dangerous in its tendencies.

That a fibrinous exudation which occurred upon the surface of the tonsil, or of the mucous membrane of the fauces, constituting a so-called croupous membrane, presented gross appearances, by which it could be immediately recognized.

That croupous membranes on the fauces of an adult marked the existence of a disease which, while being undoubtedly a blood-poison, was still a self-limited infection, and involved no danger to life.

That a croupous membrane forming in the fauces of a child marked the occurrence of the same disease as croupous membrane in an adult; but in the child there was the additional danger of a new centre of development occurring in the larynx, where it might involve the greatest danger to life, though entirely as a mechanical obstruction to respiration.

That a diphtheritic membrane developed in the fauces marked the occurrence of a disease which was dangerous to life, not only from primary and secondary septicæmia, but also from the tendency to the development of the same morbid process in the larynx.

DR. BEVERLY ROBINSON, of New York, took exception to Dr. Bosworth's views in regard to the question of follicular tonsillitis, so called, appearing as an essential fever. From a clinical point of view, he thought that this was a mistake, because, while it was certainly true that in a certain number of instances, particularly in children, the fever lasted for a number of days, and was

evidently connected with the appearance of cheesy masses over the follicles of the tonsils, yet in quite as large a number of cases the fever was of very short duration. Again, the pathological appearances of the exudation from the interior of the follicles did not, he thought, resemble, microscopically, the condition to which Dr. Bosworth alluded in speaking of the true croupous membrane, and did not in reality partake of the nature of an exudation, which was generally regarded as of a fibrinous character. With regard to the question of croupous tonsillitis, he would remark that while there might, perhaps, be many cases in which the membrane itself did characterize the type of a disease which was not a constitutional affection, he had seen cases in which the mucous membrane did not seem to be incorporated with the false membrane itself, and in which the cases seemed to be of mild type, but after a few days became very serious. The membrane, which at first was white and easily detached, afterward became dark and so attached to the underlying tissue that he could not say the case was not one of diphtheria. As regards the origin of these affections in the local absorption of certain germs, he could only say that while they had a theoretical basis, they were, to his mind, far from proved.

DR. WILLIAM C. JARVIS, of New York, said that he could, for the most part, substantiate the views of Dr. Bosworth as regards the gross pathology of the exudation met with in the upper air-passages. His attention was first called to inflammation of the pharyngeal tonsil by the occurrence of the affection in his own person several years before. A feature of acute follicular pharyngitis which did not seem to have received any attention was one in which the secretion was retained; eventually escaping upon rupture of the membrane, and covering the pharynx with a white membrane. Such a change did not occur when the inflamed follicles remained patent.

DR. F. I. KNIGHT, of Boston, wished to call attention to an important practical point which he thought escaped the attention of physicians very generally in these acute affections of the upper air-passages. This was the increased susceptibility to diphtheritic infection during the existence of any simple acute inflammation of the air-passages, and it was a fact which induced him to give a guarded prognosis in even simple, acute affections, such as follicular pharyngitis or ordinary pharyngitis.

The paper was also discussed by Drs. J. N. Mackenzie, J. H. Hartman, and F. Donaldson, of Baltimore; E. L. Shurley, of Detroit; and S. W. Langmaid, of Boston.

DR. BOSWORTH said that he must take exception to Dr. Robinson's statement that follicular tonsillitis, in any sense of the word, was characterized by cheesy deposits in the crypts of the tonsils. The resemblance of the exudation to croupous membrane was sufficiently close to warrant us in the conclusion that the two conditions were very nearly allied, if not identical, the difference being only such as one would expect to find —the membrane in the one case being deposited on the surface, and in the other being confined to the small crypts going to make up the tonsils. The points which he wished distinctly to emphasize were, *first*, that we could, by examination, throw a great deal of light on the clinical tendencies of inflammatory diseases of the fauces (a careful examination leading to a correct diagnosis); and, *second*, that mucous membrane which was in a state of acute catarrhal inflammation offered a favorable nidus for the occurrence of diphtheritic deposit, without there being any necessary connection between the two processes. The catarrhal condition was not the prodromal stage of the disease.

DR. JOHN N. MACKENZIE, of Baltimore, presented

A CONTRIBUTION TO THE STUDY OF CONGENITAL SYPHILIS,

which was, to a considerable extent, based on a case of this disease which had come under his observation. The child remained healthy from the first to the third year, when interstitial keratitis of both eyes (which continued for two years) was the first trouble to become developed. After a time paralysis of both eyelids set in, all muscular control of the lids being lost. Then followed intense occipital cephalalgia, which lasted over a month, when, together with the paralytic trouble in the eyelids, it was completely relieved under medical treatment, the exact nature of which Dr. Mackenzie did not know. Internal strabismus of the right eye next became developed, and this was accompanied with deafness of the right ear, from which there was now a slight purulent discharge. Then came ulceration of the tonsils and pharynx, with dysphagia, complicated by inflammation of the right lachrymal sac and very extensive ulcerations of the hard palate, also with pus and constant muco-purulent discharge. It was not possible to make a laryngoscopic examination, but there was absolute aphonia. The ulcerations advanced, in spite of all treatment, until the child was taken with a mild attack of scarlet fever; when, as a result of this, all the symptoms, including the aphonia, were markedly relieved for a considerable time. The child next had an attack of acute pneumonia, which lasted about four weeks, and when it was examined afterwards, it was found that the hard palate was covered with cicatrices, while the breathing was entirely through the nose.

There were two features about the case to which Dr. Mackenzie wished to direct special attention. The first was that, while deep ulceration of the lower pharynx was not infrequent, such a degree of stenosis as was met with in this patient was exceedingly rare. He knew of but two other cases on record. The second was the paralysis of both upper eyelids. This, he could not doubt, was of cerebral origin, and he thought it was probably due to the presence of a gummatous tumor.

He then referred to a paper of his, published in the *American Journal of the Medical Sciences*, for October, 1880, on "Congenital Syphilis of the Throat," which was based upon th study of one hundred and fifty cases, and stated that the opinions which he had therein expressed, had only been strengthened by the further experience that he had had since its publication, as well as by the observations of others. He believed that laryngeal disease was one of the most constant and characteristic of the pathological phenomena of congenital syphilis, and that one might look for invasion of the larynx with as much confidence in the congenital, as in the acquired form of the disease. There

was every reason to believe that such inflammations had frequently been confounded with simple and fibrinous laryngitis, and their dependence on syphilis overlooked.

The following propositions were then advanced:

First. In congenital syphilis deep ulceration may invade the pharynx and naso-pharynx.

Second. When the eruption of constitutional syphilis is apparently delayed, the pharyngeal and laryngeal affections are apt to be more serious.

Third. Females are attacked more frequently than males. Out of sixty-nine cases of pharyngeal ulceration, forty-one occurred in females.

Fourth. Ulceration may occur in any situation, but its favorite seat is the palate, especially the hard palate, for which it manifests the closest elective affinity.

Fifth. When ulceration occurs at the posterior part of the hard palate, the tendency is to involve the soft palate and velum, and thence to invade the naso-pharynx and posterior nares.

Sixth. The next most common seats of ulceration in their order of frequency, are the fauces, the naso-pharynx, the posterior pharyngeal wall, the nasal fossæ and septum nasi, the tongue and gums.

Seventh. Ulcerations, especially those of the palate, show a tendency to centrality of position, together with a special tendency to caries and necrosis of the bone.

Eighth. The tendency to necrosis exists at all periods of life.

Ninth. While deep pharyngeal ulceration generally precedes or coexists with similar affections of the larynx, the latter occurs also without evidence of pre-existing pharyngeal lesions.

Tenth. Laryngeal ulceration does not commonly follow the pharyngeal destruction of latent syphilis; those palato-pharyngeal ulcerations which are found in tardy congenital syphilis having little tendency to invade the larynx, but rather to infiltration of the naso-pharynx and nose.

Eleventh. Simultaneous or consecutive ulceration of the palate, pharynx, and nose seems to be characteristic of syphilis, or, at least, seems more frequent in this than in any other disease.

The throat ulcerations of congenital syphilis, he continued, showed a tendency to rapid progression which was often beyond control. But they sometimes subsided as if by magic on the appearance of some acute exanthematous disease. It was to this point that he particularly wished to call attention. While congenital syphilis afforded no protection against such affections, it did seem undoubtedly to mitigate the violence of the attack. Thus, scarlet fever, measles, and chicken-pox all seemed, as a rule, to exert a favorable effect on the throat-lesions of congenital syphilis, so that it was probable that the poisons of these diseases were mutually destructive. These remarks were not, however, appropriate to diphtheria, to which the victim of congenital syphilis was apt to succumb rapidly; the presence of the inherited disease greatly increasing the danger from this affection. The remarkable effect of erysipelas on the syphilides had been noted by a number of authors, and some had even proposed inoculation with erysipelatous virus as a therapeutic measure in obstinate cases of syphilis. It seemed, therefore, that there was a well-marked antagonism between congenital syphilis and certain acute exanthematous diseases. In the course of the paper, Dr. Mackenzie stated that there was no difference between the so-called scrofulous and syphilitic ulceration of the throat. Syphilis, tuberculosis, and lupus had been indiscriminately ascribed to scrofula in the matter of such lesions; but apart from these diseases, which were distinct from struma, there was no reason to believe in an ulcerative scrofulide of the throat.

DR. E. L. SHURLEY, of Detroit, could not agree with Dr. Mackenzie in regard to the identity of scrofula and syphilis, and thought that in the present state of our knowledge it was necessary to admit the tubercular, syphilitic, and scrofulous origin of the lesions referred to. While the pathological appearances of the lesions were often much the same in scrofula and syphilis, clinically, he thought, there was a very wide difference in these two diseases, both in children and in adults.

DR. MACKENZIE said, in reply, that Dr. Shurley had very much misunderstood him if he thought he said that scrofula and syphilis were the same. The idea that he intended to convey was, that there was no point of difference between the so-called scrofulous throat ulceration of the French writers, and that of congenital syphilis. Neither was there any difference between such scrofulous ulceration of the throat and that due to tuberculosis or lupus.

DR. HARTMAN related the case of a child, four years of age, suffering from congenital syphilis, who had an attack of measles, by which the ulceration existing in the naso-pharynx, so far from being alleviated, was considerably aggravated. After it had recovered from the measles, consequently, the throat was left in a worse condition than before the attack. This, of course, was only a single case; but it went to show that such cases were not always benefited or controlled by the intercurrence of an acute exanthematous disease.

DR. DONALDSON remarked that he had understood the author of the paper to question the existence of scrofulous ulceration of the throat in young children not connected with congenital syphilis. He then related a case now under his care, a child of five years of age, the son of a healthy farmer, who had, with a large ulcer of a scrofulous character over the soft palate, unmistakable evidences, such as enlargement of the lymphatic glands, etc., of scrofula, and none of the usual symptoms of congenital syphilis.

DR. KNIGHT said that his experience in this class of cases was very limited, but he believed, with Dr. Mackenzie, that a careful search for the origin of the trouble present would reveal the history or certain evidences of syphilis, and, if not of that, of tubercle. As in the adult, we could not always, perhaps, get a satisfactory syphilitic history, but antisyphilitic treatment generally yielded such results as to justify us in considering the disease to be of a syphilitic nature.

DR. BOSWORTH remarked that the more experience he had in the matter, the more convinced did he become that, as far as the mucous membrane of the air-passages was concerned, there was no difference between the ulceration of congenital syphilis and scrofulous ulceration. He said that he would have been glad if Dr. Mackenzie had directed some attention to the question of treatment. In his own practice (so far had

he become convinced of the identity of the two conditions), he had of late years depended almost entirely upon the administration of mercurials, and in many cases the results had been eminently satisfactory. This seemed to him additional proof of their identity.

DR. MACKENZIE, in closing the discussion, said that he had especially avoided generalization in his paper, and had only stated that, in his experience in this class of cases, the ulceration was often cured or relieved by an acute intercurrent disease. In Dr. Donaldson's case, he did not see how a diagnosis was to be made between syphilis and scrofula, and Dr. Knight had pointed out how difficult it often was to get at the facts of a syphilitic history. With regard to treatment, he was in the habit of relying upon mercurials and the iodide of potassium, using iodoform locally.

APPOINTMENT OF COMMITTEES.

Before adjournment, the Chair appointed on the *Nominating Committee*, Drs. Knight, Lefferts, and J. Solis Cohen; and on the *Auditing Committee*, Drs. Mackenzie and Hooper.

ELECTION OF NEW FELLOWS.

Drs. S. Solis Cohen, of Philadelphia, and Clarence C. Rice, of New York, recommended for membership by the Council, were then duly elected Fellows.

AFTERNOON SESSION.

DR. J. O. ROE, of Rochester, N. Y., read a paper on

RETROPHARYNGEAL ABSCESS.

Having alluded to the location of abscesses in general, he said that the post-pharyngeal connective tissue was liable to this affection, first, on account of its low vitality; and, secondly, on account of its looseness. Retropharyngeal abscess might originate either in the soft tissues, or from necrosis of the cervical vertebræ, and the former variety might have its origin either in the glandular structure or in the areolar cellular tissue. Having given a sketch of the anatomy of the parts, and especially their glandular connection, he mentioned the causes of retropharyngeal abscess as being either (1) idiopathic, (2) traumatic, or (3) secondary. Among the first were included cold, nasal catarrh, retropharyngeal lymphadenitis, and the scrofulous, tubercular, and syphilitic diatheses. Traumatic abscesses were such as were caused by direct wounds, or by injury from the swallowing of bones, and other similar accidents. Those of secondary origin were such as were dependent on tonsillitis, pharyngitis, or other local affection in the vicinity.

Among the symptoms were mentioned dysphagia and dyspnœa, and the latter might be so urgent as to necessitate tracheotomy if the true nature of the trouble was not recognized. Convulsions were sometimes caused by it in children. Among the other symptoms mentioned as liable to occur were facial paralysis, soreness about the palate, stiffness and swelling of the neck (the head being often bent to one side, if the abscess were laterally situated), and œdema of the larynx, which sometimes caused sudden death. In the diagnosis of this affection, it was necessary to differentiate it from croup, the presence of foreign bodies in the throat, œdema of the larynx, and even enlarged tonsils. The voice was always more or less altered, and in children it might be altogether extinguished. A correct diagnosis could only be arrived at by careful inspection and digital examination. Lipoma of the pharynx had sometimes been mistaken for retropharyngeal abscess, and in one case, in his own practice, the diagnosis of the former had to be established by an exploratory incision. When there was much dyspnœa, the head was usually bent backward considerably. The prognosis was least fatal in the idiopathic variety, much more so in the secondary.

The only treatment for retropharyngeal abscess was prompt evacuation. There was some danger of sepsis supervening, and, therefore, it had been recommended, by some, that a canula should be employed to remove the pus. Dr. Roe thought it well, in some cases, to make quite a small incision at first, as advocated by Allis, for fear of some of the contents of the abscess getting into the larynx, and afterwards enlarging it so as to insure complete maceration of the sac.

Having mentioned that the disease was practically one of infancy, fully one-half the cases occurring in the first year of life, he related three cases which he had been called to see in consultation. The first was in an infant, nine months old, who was supposed to be suffering from diphtheretic croup. There was, however, an entire absence of the constitutional disturbance characterizing this affection, and a careful examination soon revealed the true state of affairs. In this instance there was marked swelling of the neck, extending from the clavicle to the ear, on the left side. He made a small incision at first, so as to allow the pus to escape slowly, and at the same time bent the head forwards; later making the incision larger. There was no return of the trouble, although the child had been weak and cachectic from birth.

The second patient was ten months old, and had had an attack of scarlatina two weeks before the occurrence of the retropharyngeal abscess. There was still remaining considerable coryza and conjunctivitis. One evening it was noticed that there was considerable difficulty in breathing and in swallowing, and that the voice was markedly altered. The attending physician feared that diphtheria was setting in, but the presence of the abscess was recognized by Dr. Roe, who made an incision in the same manner as in the preceding case, after which there was no further trouble.

The third case occurred in a student, twenty years of age, who, after attending a class supper, suffered from headache, diarrhœa, and sore throat. The neck was considerably swollen, and Dr. Roe found that there was a retropharyngeal abscess. This was freely opened, but the pus burrowed downwards in the tissues, so that the abscess became retro-œsophageal. There was a very profuse discharge, and the inspiration sounded as if the patient was breathing through soap-bubbles. He died from exhaustion on the third day.

DR. T. A. DE BLOIS, of Boston, said that he also had had three cases of retropharyngeal abscess. What had impressed him most in connection with all of them, was that the head was carried very far backward, so that this of itself made the diagnosis an easy one, and he thought that Dr. Roe had hardly laid sufficient stress upon this point. One of the cases was in an adult, and the other two in children; and in one the

incision had to be carried through the posterior pillars of the fauces. He did not agree with Dr. Roe in regard to the small incision, but thought that it should be free, and the pus at once evacuated; though after the incision the head should be forced down.

DR. S. JOHNSTON, of Baltimore, wished to call special attention to the advantages of the free horizontal incision in retropharyngeal ulcers. In the case of a child he had made this, and then inverted the patient; at the same time carrying his finger into the throat. The result was the complete and satisfactory evacuation of the abscess; nearly a wine-glassful of pus escaping.

DR. W. C. JARVIS, of N. Y., thought that more stress should be laid upon the occasional occurrence of retropharyngeal abscess in connection with ordinary phlegmonous tonsillitis. A case of this kind had come under his observation, in which this condition existed, along with acute suppuration of the tonsil, and almost resulting in the strangulation of the patient.

DR. GEORGE M. LEFFERTS, of New York, said that one clinical fact, well observed, was worth pages of theory. Who of those present, he asked, believed that nasal catarrh in children was even a cause of retropharyngeal abscess? Or, if it was, why was the latter not oftener met with? Having expressed doubt as to tuberculosis of the pharynx (in itself so extremely rare that some denied its occurrence altogether) or injury to the posterior pharyngeal wall ever being causes of this trouble, he went on to say that retropharyngeal abscess, apart from that form arising from caries of the vertebræ, was probably due to a simple phlegmonous inflammation of the cellular tissues in front of the spinal column. As to the matter of diagnosis, it seemed to him that there was little value in speculating whether the patient's head was held forwards or backwards, whether inspiration or expiration was most affected, and the like variety of symptoms that had been alluded to. One look into the patient's throat was sufficient. Few conditions could be confounded with retropharyngeal abscess; a suppurating gumma was one. In treatment, again, why not sum up the matter in one word by saying that retropharyngeal abscess must be treated upon the same surgical principles as an abscess elsewhere in the body—open it and discharge its contents? The affection, he thought, must be very rare. In literature comparatively few examples were met with, and in all his experience he had seen but two examples. Both were in young children, and both were operated upon by simple incision. There was no difficulty in the diagnosis, and both recovered.

DR. J. SOLIS COHEN remarked that the danger of suffocating the patient on incision of the abscess might be avoided by operating with the head pendent. As to the horizontal incision recommended by one of the speakers, he believed that the danger of leaving a pocket in the lower portion of the abscess, in which pus might accumulate, had been mentioned by some authors as a reason for prefering the vertical incision.

Remarks were also made by Drs. Donaldson, Major, Lincoln, Mackenzie, Ingals, and Chamberlain, and the discussion was brought to a close by Dr. Roe.

CONGENITAL WEB OF THE VOCAL BANDS

was the title of a paper read by DR. T. A. DE BLOIS, of Boston. The patient was a young woman twenty years of age, whose voice had always been weak and puerile. She was first under the charge of his colleague, Dr. Fowler, and afterwards came under his own care. She had a very dependent epiglottis, and on account of the extreme irritability of the parts it was very difficult to get any view of the larynx for a long time. When the intolerance had been partially overcome by a course of education, it was found that over the anterior half of each vocal band there was spread a strong white web, the appearance of which was shown in colored drawings exhibited by Dr. De Blois. He determined to break up the adhesions, if possible, and so introduced Mackenzie's forceps for the purpose. Instead of tearing the web, however, the instrument merely scratched it; but in a subsequent attempt he succeeded in splitting it across by the same means, leaving a jagged, dentated edge on each side. The next day he found, to his chagrin, that the torn surfaces had again united; but he afterwards ripped up the new cicatricial tissue with a probe. The treatment of expansion had been continued by Dr. Fowler, and the voice had become natural in tone; while the singing voice had gained three notes upwards and four downwards. The bibliography of this condition was very meagre, and, so far as he knew, there were but three cases on record. These he then gave.

DR. M. J. ASCH, of New York, said that pertinent to the case of Dr. De Blois was a case he himself had had, in which he found a web occupying the anterior portion of the glottis, the result of acute inflammation. There was also a vertical web in one eye, stretching from the palpebral to the orbital conjunctiva. There was originally no laryngeal trouble, but the patient eventually became the subject of laryngeal phthisis.

DR. HARTMAN questioned the advisability of the introduction and forcible expansion of a pair of lateral forceps in the larynx, and said he would prefer the curved or tube bistoury, or the galvano-cautery, for division of webs.

DR. WM. H. DALY, of Pittsburg, read a paper on

GUNSHOT WOUND OF THE LARYNX, INVOLVING THE VOCAL BANDS.

In connection with a case which he related, he gave complete statistics and a bibliography of this injury. He had expected to present the patient, but the latter had found it impossible to attend.

DR. J. SOLIS COHEN stated that having had recent occasion to study the subject of gunshot wounds of the larynx, he had been astonished to find how infrequent they had been in military practice. He had had the opportunity of examining Dr. Daly's patient, and had at that time doubted if the ball had really traversed the larynx; but in view of the subsequent history of the case, he could not but admit that his previous opinion had been an incorrect one.

DR. LEFFERTS said that a specimen of gunshot wound of the larynx was in his collection in the museum of the College of Physicians and Surgeons, but, unfortunately, without history. The presence of a tracheotomy wound showed that the ball had remained in the larynx, and necessitated tracheotomy for dyspnœa.

DR. ASCH remarked that gunshot wounds of the larynx were extremely rare. As a medical officer of the United States Army for twelve years, and Acting

Medical Inspector of the Army of the Potomac during the Wilderness campaign of 1864, he saw not a single case of this character.

DR. J. SOLIS COHEN, of Philadelphia, reported

A CASE OF COMPLETE PARALYSIS OF THE LEFT VOCAL BAND IN EXTREME ABDUCTION, THE RESULT OF AN INCISED WOUND OF THE NECK.

The patient was thirty-three years of age, a drug-clerk, and a slave of the opium-habit. He was seen at the Jefferson Medical College, Philadelphia, in November, 1883, and said that in the June previous he had had his throat cut by thieves near Omaha. In attempting to cry out his voice gave way, and ever since there had been complete aphonia. While the right vocal band was normal in position, the left was found fixed in extreme abduction. On forced inspiration the right band did not go quite as far over as the position in which the left constantly remained. The man's account of himself was believed to be utterly unreliable, and there could be no doubt, from the position of the cicatrix in the neck (a plaster cast of which was exhibited), that he had attempted to commit suicide. The sterno-cleido-mastoid muscle had been severed, and the wound was deepest directly in the track of the pneumogastric nerve. There was no pulsation in the carotid artery, which was probably due to the fact that it was tied by the surgeon called to attend the man after the receipt of the injury. The wound was made from behind forwards, and there was a gashed appearance about the cicatrix, as though several slighter cuts had been made before the main one. The case, he believed, was altogether unique. Colored drawings were exhibited, showing the position of the vocal bands in inspiration, expiration, and forced inspiration.

DR. BOSWORTH remarked that he thought that this was the first case yet reported which would throw light on the subject of true abductor paralysis of the vocal bands, and the case was discussed by a number of other Fellows.

In the evening THE PRESIDENT, DR. BOSWORTH, gave a

RECEPTION

at his residence to the Fellows.

TUESDAY, MAY 13TH, SECOND DAY.

MORNING SESSION.

DR. F. H. HOOPER, of Boston, reported

A RARE FORM OF TUMOR (CAVERNOUS PAPILLOMA) OF THE VOCAL BAND.

The case was seen by Dr. Knight on November 22, 1882, but at that time refused all operative interference. The following year the case was referred to Dr. Hooper. The patient was a clergyman, thirty-two years of age, and said that the trouble commenced in September, 1882, when he suffered from a cold, with hoarseness. The cold lasted about three weeks, but the hoarseness continued persistently up to the time that the case came under observation. Apart from the hoarseness, there was no symptoms referable to the larynx, except a more or less constant scraping of the throat. A laryngoscopic examination revealed the presence of a small, nodular, sessile growth on the anterior portion of the left vocal band, about the size of a No. 7 shot. It presented some of the characteristics of a cystic tumor, but the diagnosis could not be determined with accuracy on inspection. At the patient's second visit, Fauvel's forceps were introduced, more for the purpose of testing the tolerance of the larynx than with any idea of removing the growth; but when the instrument was withdrawn and placed in a glass of water, much to Dr. Hooper's surprise, the tumor was found to have come along with it. It had been thus easily knocked off by the blade of the forceps, and had fortunately remained adhered to it. The hemorrhage was quite insignificant. The tumor (drawings of the microscopical sections of which were presented for examination) was referred to Dr. W. W. Gannett, Pathologist to the Massachusetts General Hospital, for examination, and he expressed the opinion that it was a cavernous papilloma. It contained a cavity which was filled with red blood-corpuscles, and he stated that he thought it had consisted of cavernous tissue from the start. The patient's voice was at once completely restored, and he left town for his place of residence the day following the removal of the growth.

Since then there had been no return of the trouble, and he had recently written Dr. Hooper that, during a series of special meetings lasting six weeks, he had spoken almost every night, and that his voice was "as good as ever." The only case of similar character that had as yet been reported, as far as the author was aware, was one described by Fauvel.

DR. CARL SEILER, of Philadelphia, stated that he also had had a case very similar to that of Dr. Hooper, with the exception that in his the epithelial structure was not as far developed as in the latter, the tumor being more of an angioma. The patient in whom it occurred was a student of elocution, and the only symptom of which he complained was hoarseness.

DR. MORRIS J. ASCH, of New York, reported

A CASE OF ENCHONDROSIS OF THE LARYNX.

Having stated that cartilaginous tumors of the larynx were very rare, he gave a complete *résumé* of the literature of the subject. There were only two cases, he said, in which the true character of the growth was recognized, and in but one of these was endolaryngeal methods of treatment employed. Dr. Asch's patient was forty-two years of age. He suffered from constant irritation of the throat, attended with hoarseness. He was an amateur vocalist, and the trouble in the larynx was a continual source of annoyance. The tumor was situated in the left aryteno-epiglottidean fold, and, on account of its marked hardness, Dr. Asch was enabled to make a correct diagnosis before its removal. This was accomplished by means of a modification of Stœrck's guillotine, in which the ring was made of well-tempered steel, with the cutting edges on the upper border. It was very difficult to get the tumor surrounded by the ring; but when this was finally accomplished the growth was removed without difficulty, and there was no hemorrhage. The restoration of the voice was complete, and the patient found that two notes were actually added to his register. The specimen was submitted for microscopic examination to Dr. George L. Peabody, Pathologist to the New York Hospital, who reported that each section of the tumor showed cartilage at the centre, and that it contained carbonate of

lime in considerable quantities. It was, therefore, a cartilaginous growth undergoing calcareous degeneration. He considered the case of interest to laryngologists, then, not only for the diagnosis, which showed it to be a very rare condition, but also from the fact that a cure had been effected by endolaryngeal methods.

DR. J. SOLIS COHEN said that he had never met with a case of this character in his own practice. In one or two instances he had thought he had to deal with cartilaginous growths of the larynx, but found subsequently that they were fibroids. He could hardly understand why the marked increase in the vocal register had followed the removal of the tumor, since the latter was situated outside of the vocal tract.

DR. SEILER thought it was perhaps due to increased resonance depending on the moral effect upon the patient from a sense of relief about the vocal apparatus.

DR. LANGMAID expressed the opinion that the increase in the voice was probably due, first, to the removal of irritation, and, second, to the feeling of enthusiasm on the part of the patient; and Dr. Asch agreed with him in this explanation.

DR. W. C. JARVIS, of New York, read a paper on

A NEW METHOD FOR THE REMOVAL OF LARYNGEAL GROWTHS.

In commencing, he said that the procedure to which he wished to direct attention on this occasion was the use of chromic acid for the removal of laryngeal papillomata. It was his practice to employ crystals of the acid fused on the point of a probe. The usefulness of this method depended on the affinity of this salt, which was properly the trioxide of chromium, for soft papillomatous tissues. The advantage of its action was that it was self-limited, and thus, as an escharotic, this agent was safe, harmless, and yet sufficient. It had a very restricted action on normal mucous membrane, and this added safety as a caustic agent.

There was a pronounced opinion in the minds of laryngologists, he continued, against the use of chromic acid, and he quoted a passage from Morell Mackenzie in opposition to its use. The reason for this unfavorable opinion, he thought, was on account of its improper employment on the part of certain operators, who had used it in such large quantities as to make its application both painful and dangerous. When properly employed, however, as he had found by experience, the salt, in the first place, enucleated the laryngeal growth, and, secondly, prevented the return of the neoplasm. One serious objection to the nitrate o silver was the tendency of its action on the tissues to spread; but the most important difference between chromic acid and the latter was its deliquescent character. The nitrate of silver, on the other hand, was wholly insoluble.

The great points in the successful use of chromic acid in this connection were tha it should be applied in small quantity, and the application frequently repeated. In making the application it was advisable to keep the point of the probe in the field of the laryngeal mirror, so that it could be directed with precision. The probe having been heated, a small quantity of the acid was placed upon it, and the papillomatous tissue was removed piecemeal. The curve of the probe, he thought, had much to do with the success of the procedure. As the use of the uncovered probe was sometimes attended with more or less difficulty, he had devised a canula provided with a spring, which was controlled by a trigger (instrument exhibited). The advantages of this were, first, that it prevented the chromic acid from coming in contact with the tissues before reaching the seat of growth; and, second, that it enabled the operator to surprise the larynx. It was so arranged that the force of the spring could be exactly regulated, and forcible impact of the caustic avoided.

The general applicability and utility of this method he thought very wide He then gave a history of the case in which he had first been led to adopt the treatment. The patient was a lady, thirty years of age, who was sent to him from Norwalk, Conn. She was suffering from more or less dyspnœa and frequently recurring spasm of the larynx. Her voice was a discordant whisper, and the laryngoscope revealed a very large growth, almost entirely filling the laryngeal cavity. By way of testing the tolerance of the parts, he introduced a probe, but it gave rise to such intense spasm that the patient's life seemed endangered. He proposed to perform tracheotomy, but as the patient would not entertain the thought of this, he determined to try the effect of applications of chromic acid. Accordingly, he resorted to this procedure, and was gratified to find that the caustic application produced neither spasm nor cough. He then applied the acid every day, and sometimes two or three times at a sitting, and at the end of nine days the patient recovered her natural voice. This was really as the result of five days' treatment, since during four of the nine days circumstances prevented the patient from attending. The treatment was commenced on the 14th of February, and was continued until the 4th of March; by which time every vestige of the tumor had disappeared, and he regretted very much that she was not present to show the result. (Dr. Jarvis exhibited large colored drawings of the growth.) He did not wish to exclude the use of the forceps and the snare, but at the same time he claimed that the opprobrium which had been cast upon chromic acid was unjust and unfounded.

In conclusion, he summed up the contents of the paper in the following propositions:

1. Trioxide of chromium, or chromic acid, is self-limited in its action. 2. It offers a safe and reliable means for the removal of large and small soft laryngeal growths. 3. It not only removes such growths, but also serves to prevent their return. 4. It is best applied fused on the point of a probe. 5. A tubular instrument can be employed to protect the tissues and guide the application. 6. Its use is not necessarily attended with pain and spasm. 7. It offers a substitute for tracheotomy and thyrotomy in certain cases in which these measures are ordinarily judged necessary.

DR. J. SOLIS COHEN said that it had been so long since he had used caustics for the removal of such growths from the larynx, that he had almost forgotten that he had ever done so. In such cases he had usually operated with instruments, but had sometimes applied escharotics afterward. He was glad that Dr. Jarvis had given such detailed directions for making the applications of chromic acid, as everything depended on the way in which the procedure was carried out. The results seemed to him very remarkable, and

he did not know of any other means which would have eradicated so large a growth as that described by Dr. Jarvis, in such a short time.

DR. ROE had sometimes employed chromic acid, but not until after the use of instruments. In one case of aphonia, of about eight years' standing, occurring in a patient eighteen years old at the time of coming under observation, he found a papilloma almost as large as the one described by Dr. Jarvis. He removed the growth by instruments, and then applied bichromic acid, for which he used a device somewhat similar to Dr. Jarvis's, in which the applicator was hid in a sheath. In several other cases he removed little nodules, and touched the bases with bichromic acid.

DR. SEILER said that he also had been using an instrument very similar to Dr. Jarvis's for surprising the larynx. It was provided with a pistol trigger, and its action was perhaps not as neat as that of the one now exhibited.

DR. INGALS, of Chicago, said that he sometimes resorted to a simple device for making a caustic applicator that was sufficiently protected for all practical purposes, and that was to take a piece of aluminium wire, and slip a piece of rubber tubbing, such as dentists use over its end. To make applications in certain positions it was sometimes advisable to cut out a piece of the rubber tubing at one side. He had used other caustics, but not chromic acid, in papillomatous growths. In one case of adenoid cancer, however, he was employing it freely, and without any bad results.

DR. MAJOR, of Montreal, said that in the case of infants and young children, he had found the use of absolute alcohol, applied by means of a spray, of very great advantage. While it would not perhaps remove large growths of the larynx, it would cause such shrinkage in them that tracheotomy could be dispensed with, and the patient got along comfortably until sufficiently large to have an operation performed for their removal, whether by caustic or otherwise.

DR. JARVIS said, in closing the discussion, that in many cases in which the size and position of the growth were such as to produce intense spasm, instrumental interference was out of the question, on account of the danger of bringing on a fatal result; but when the growth was not sufficiently large to cause reflex spasm, instruments could be used with impunity, whether a certain amount of irritative spasm be produced or not.

THE PRESENTATION OF INSTRUMENTS

being now in order, among those exhibited were a nasal speculum, by Dr. Mackenzie; a tonsillitome, with three blades, and a new uvulatome, by Dr. S. Solis Cohen; and an apparatus for artificial feeding, by Dr. Delavan.

SECOND DAY—AFTERNOON SESSION.

THE PROPOSED NEW NOMENCLATURE

was in order for discussion, but, on motion of Dr. Knight, of Boston, the matter was referred to the Council for consideration, after which it was to be reported for adoption.

DR. D. BRYSON DELAVAN, of New York, then read a paper on

PERMANENT UNILATERAL PARALYSIS OF LARYNGEAL ABDUCTORS, FOLLOWING CEREBRAL HEMORRHAGE; UNIQUE CASE.

The case was one which, he thought, would be of interest to the Association, not only on account of its extreme rarity, but also as affording an opportunity for the discussion of the vexed and unsettled question of the etiology of abductor paralysis. The only distinct reference to this lesion which he had been able to find in the whole range of medical literature, was in Nothnagel's article on cerebral hemorrhage in *Ziemssen's Cyclopædia*, in which he simply says that unilateral paralyses of the vocal ends are exceedingly rare. The patient who was the subject of the affection was a gentleman sixty-nine years of age, who belonged to a long-lived family, in which there were, however, some tubercular and rheumatic tendencies. He was of temperate habits, but used tobacco freely. Since middle life he had suffered more or less constantly from rheumatism, and he was also troubled at times with pharyngeal catarrh. In 1876 he had a seizure which was apparently of a vertiginous nature, from which he recovered promptly, without any bad consequences; but in 1877 he had a well-marked apoplectic stroke. This was followed by complete hemiplegia, and, in addition to this, his voice assumed a cracked, piping, and uncertain tone. There was also facial paralysis, with distinct ptosis. For several months there was a slow but steady improvement, until all trouble disappeared, except that in connection with the voice, which remained practically the same.

In 1882, Dr. Delavan first had an opportunity of making a laryngoscopic examination, and he found that there was complete paralysis of the right laryngeal abductors, the vocal band of that side lying directly in the median line. This condition had now lasted for seven years. From the paralysis of the laryngeal abductors occurring at the same time and apparently in connection with hemiplegia, the result of cerebral hemorrhage, it would seem at first sight to establish the existence of independent ganglionic centres for the abductors; but the fact that all the other paralyses disappeared after a time, while this abductor paralysis remained permanent, certainly militated against such a hypothesis, though it did not positively exclude it.

DR. KNIGHT considered this matter of abductor paralysis a subject of interest, but doubted whether any of those present were prepared to add anything new in regard to it. He had, however, seen one case which seemed very pertinent to the paper. It was that of a patient who fell down stairs, striking his head, and whose voice was at once found to have become entirely altered in tone. This was the only trouble from which he suffered, and the examination of the larynx showed paralysis of the abductors. There must, therefore, have been some lesion which affected the abductors without implicating the adductors,—probably an injury to either the nerve or the nerve-centre.

DR. DELAVAN remarked, in conclusion, that he had simply offered a clinical fact, which he trusted might add a mite to our knowledge on this obscure question, and that he had no theory of his own to advance.

DR. R. P. LINCOLN, of New York, reported a case of

STRICTURE OF THE ŒSOPHAGUS.

The patient was a native of Hayti, fifty years of age,

and was referred to him by Dr. F. N. Otis, in June, 1883, when he was suffering from aphonia, dyspnœa, dysphagia, regurgitation of food into the nares, and more or less constant pain. These troubles had commenced, he said, eighteen months previously.

An examination showed him to be suffering from rhinitis, pharyngitis, and laryngitis, and he said that he had been previously treated for syphilitic laryngitis by the internal administration of iodide of potassium and locally by the application of nitrate of silver, tannin, etc. Inspection showed a general fulness of the neck, extending from the cricoid cartilage down to the clavicle; while the thyroid body was considerably enlarged. The epiglottis was red and thickened, and there was stenosis of the larynx. There was extreme sensitiveness of the pharynx and larynx, and no attempt was made at this time to pass sounds into the œsophagus. The presence of a stricture of the latter was indicated opposite the seventh cervical and first dorsal vertebræ on auscultation when the patient swallowed fluid. He was placed on the use of iodide of potassium, while oleate of mercury was rubbed into the enlarged cervical glands, which became softened and less sensitive, though they did not diminish in size. At the same time local applications were made, by means of spray, to the pharynx and larynx, and his whole condition became considerably improved. Afterwards, however, he grew worse, and the skin was noticed to be somewhat cyanosed, while he also suffered from delusions.

Under the use of steam inhalations and hypodermic injections of morphia, he again improved, though the obstruction to deglutition still continued. The attempt to pass sounds or bougies was always followed by inflammation; but once Dr. Lincoln succeeded in introducing a metallic sound. Severe inflammation followed, but later, Dr. Weir passed a bulb-pointed catheter without occasioning any inflammatory trouble. For a time, he seemed considerably relieved, receiving three nutrient enemata a day, in addition to hypodermic injections of cod-liver oil; but in September he died. The autopsy showed that the disease was medullary cancer. It began in the anterior wall of the œsophagus, and the cervical glands, as was usual in such instances, shared in the affection. The vagi nerves were implicated, and death resulted from interference with the cardiac branches of the same.

Dr. Roe suggested that the bougies should have been left *in situ*.

Dr. Daly thought that gastrostomy migh have been tried.

Dr. Donaldson stated that he could not think it necessary to resort to gastrostomy in cases of stricture of the œsophagus from adhesive inflammation resulting from caustic fluids, as had been recommended by some. He related a case occurring in a child two years of age, who swallowed concentrated lye; when in two weeks it was found that there were two strictures of the œsophagus, one about the seventh cervical vertebra, and the other near the cardiac orifice of the stomach. Soft œsophageal bougies were introduced more or less continuously for over two years; the tube being thereby kept open. Should he have another similar case, he would keep the œsophagus open by allowing a perforated tube to remain in it, as had been done by others.

Dr. Lincoln closed the discussion, and said, in reply to Dr. Roe's criticism, that it should be borne in mind that any attempt at interference with the œsophagus, at least any sufficient to pass a sound, was always followed by great inflammatory reaction. Moreover, there was a prompt improvement, attributable, apparently, to the soothing treatment at first instituted, which seemed to justify its continuance. In regard to Dr. Daly's suggestion, that gastrostomy might have been tried, he wished to say that while the statistics of operations so far reported gave but little encouragement for its adoption in any case, certainly the sequel in this instance showed that it would have been useless; the cause of death having been pointed out to have been due to implication by the disease of the cardiac branches of the vagus.

Dr. E. Fletcher Ingals, of Chicago, read a paper on

TRACHEAL STENOSIS.

During the past year he had met with three cases of this affection (all due to syphilis), which he related in detail. The first patient, after making a fair amount of improvement, died, his decease being attributed, to asthma. In this case, Dr. Ingals said, life was undoubtedly prolonged for many months by the use of large doses of iodide of potassium, which he recommended very highly in this kind of trouble. In the second case this acted so favorably that there had been no return of the severe symptoms, which were at no time urgent, and the patient was able to attend to business regularly. In the third case it was necessary to perform tracheotomy.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—E. L. Shurley, M.D., of Detroit.

Vice-Presidents.—Drs. J. H. Hartman, of Baltimore, and Wm. H. Daly, of Pittsburg.

Secretary and Treasurer.—Dr. D. Bryson Delavan, of New York.

Librarian.—Dr. T. R. French, of Brooklyn.

Council.—Drs. F. Donaldson, of Baltimore, and F. H. Bosworth, of New York.

THE ANNUAL DINNER

of the Association was given at the University Club.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Thirty-fifth Annual Session, held at Philadelphia, May, 14, 15, and 16, 1884.

The Society was called to order in the Hall of the Union League by The President, Dr. Henry H. Smith, of Philadelphia.

The register of delegates, numbering two hundred and fifty, was accepted without being read.

THE ADDRESS OF WELCOME

was then delivered by Dr. J. B. Roberts, Chairman of the Committee of Arrangements, who, on behalf of the Philadelphia County Medical Society, extended a cordial greeting.

The President then introduced the Governor of Pennsylvania, Hon. Robert E. Pattison, who in a few remarks said that Pennsylvania derives exceptional honor from the character and reputation of her medical profession. Its ranks are full of great names and its history with great achievements. You have wisely chosen

Philadelphia as a meeting-place, and while here, your Society may be regarded as set upon a hill. It should be remembered that it was here that the first system of medical study was formulated in this country, and from this has sprung the present University of Pennsylvania. Philadelphia may be regarded as the Odessa of medicine; she has sent forth many great men, among them one whose death I greatly deplore, a man honored by Oxford and Cambridge, Prof. S. D. Gross, by whose death the medical fraternity has suffered a great loss. The history of medicine is the history of the human race, and its progress is reflected as man progresses from idolatry to enlightenment. There is no other profession that demands of its members, so urgently and pressingly, that its members shall be distinguished by great learning, devoted sincerity, and spotless honor as this. I hope, for the sake of this Commonwealth, that the results of this session may be to the advantage of the medical profession in Pennsylvania.

THE COMMITTEE ON PUBLICATION

presented the following:

Resolved, That in future no paper read before the Pennsylvania State Medical Society shall be printed in the *Transactions* if they have been published elsewhere, unless such previous publication shall have been simply in abstract.

The resolution was referred to a special committee, with instructions to report the following day. Drs. Traill Green, Stewart, Wood, of Allegheny, Allis, and Purcell were appointed the committee.

THE MEDICAL EXAMINERS OF COUNTY SOCIETIES

reported that twenty men had applied for examination; of these thirteen passed and seven were rejected.

THE REPORT OF THE COMMITTEE ON THE APPEAL OF THE AMERICAN ANTI-VIVISECTION SOCIETY

was presented by Dr. S. Weir Mitchell, Chairman. It recited the bad effects in England of the interference of a similar society there in securing legislation hostile to original investigation. The operation of the English law has put an end to physical research. One eminent physician who has been investigating snake poisons has been obliged to give up his inquiries, and this in face of the fact that from 25,000 to 30,000 people are killed in India every year by snake bites, and the Indian Government has actually sent snake poison to Philadelphia, and money, also, to secure investigation, not being able to have such researches made in England. In the latter country, of forty-seven eminent and skilled men who were asked as to the value of vivisection, forty-five answered in favor of it, and only two against it, and in a convention in London in 1881, twenty-four hundred of the most learned physicians pronounced that experimentation upon living animals was indispensable to the future progress of medicine, and it was not desirable to restrict such experiments. It told the members that efforts will be made in the Legislature to pass an anti-vivisection law, and each of them ought to see that such a bill is defeated, and not have our great medical schools crippled, as they have been in England. In Washington, recently, at the American Medical Association, a unanimous vote was recorded against restriction. The report recommended the adoption of the following resolution:

Resolved, That in view of the attempts which have been or may be made to obstruct, by restrictive legislation, the progress of experimental medicine, this Society desires to express its earnest conviction that experimentation on animals is a most useful source of knowledge in medical science; that it is the means by which many important discoveries, both practical and scientific, have been accomplished; that its direction and supervision can be properly entrusted only to members of the medical profession, and that its restriction or prohibition by law would inevitably retard the acquisition of knowledge in respect to healthy and morbid actions, the causes and prevention of disease, and the improvement of the medical art.

The report was adopted unanimously and the Committee continued, to urge the views of the Society on the Legislature.

The amendment to By-laws, Article V., offered by Dr. Henry Leffmann, on behalf of the Philadelphia County Medical Society: Add as Section 8: "No paper shall be read before this Society unless the same has been previously read, either in full or in abstract, before a County Society, and by it referred to this Society," was indefinitely postponed.

MISCELLANEOUS BUSINESS.

A resolution was adopted recommending the passage of a law preventing the adulteration of drugs and medicinal preparations, as recommended by the Pennsylvania Pharmaceutical Association.

A resolution to appoint a committee to take action in regard to legislation looking to the regulation of the sale of alcohol was lost.

AFTERNOON SESSION.

THE ADDRESS IN HYGIENE AND STATE MEDICINE

was delivered by Dr. Benjamin Lee, of Philadelphia. He took for his subject, *The Present Outcome of Sanitary Agitation in Large Cities in the United States.*

In no department of governmental supervision do the United States of America make so poor a showing, as in that of the care of the public health. With limited areas and in small communities, much may be accomplished by private effort, and this fact hygienists have not been slow to appreciate. A go-between was needed to interpre their teachings to the masses, and impress upon them their importance. This agency has developed itself in voluntary sanitary associations, modelled upon one started in the ancient and filthy city of Edinburgh. The first in this country was started in Newport, Rhode Island. This was followed by a second in Lynn, Mass., and a third in Orange, N. J., then in rapid succession by others in other cities and villages, until now there are not less than a hundred and seventy in active and beneficent operation throughout the country, that of Brooklyn, L. I., being the largest and most important. The objects of these associations are, first, self-protective, by indicating, as far as may be, sanitary defects and dangers in the homes of their members, and of neighbors of their members, suggesting remedies for such defects, and urging their application; and secondly, educational, (*a*) in the most practical way by actual demonstration of the necessity for, and the benefits of, sanitary science, as above stated, and (*b*) by the dissemination of popular tracts expressed in simple, intelligible, and forcible language, giving both general

information and practical hints in detail as to the sanitation of the dwelling. Such an association is in reality a mutual insurance company for the preservation of private and public health. It is not intended as a substitute for municipal inspection, and will not conflict with the public health authorities, where such exist, but will supplement their action.

DR. E. A. WOOD, of Allegheny, then spoke concerning the importance of organizing a

STATE BOARD OF HEALTH.

Ignorance and prejudice, he said, were the chief obstacles in the way. The community would have to be educated to know and see the dangers before they would try to remedy them. He thought that disease had had its sway too long, and that the true treatment of many diseases dependent on a special germ was the stamping out of the germ.

DR. HENRY LEFFMANN, of Phila., read a paper on

PROPER MEDICAL EDUCATION.

The present system of medical education is not the result of efforts to meet the needs of the community, but is largely an irregular development. The reforms which medical colleges have adopted have been mostly unwilling concessions to public sentiment, and the extension and success of post-graduate schools indicate the direction in which the improvement of the curriculum should be made. A preliminary training for the student before entering on the study of medicine, is so obviously necessary that it need not be argued. The final work of medical reform will be accomplished when the college is made merely the instructor, the license to practise being given by an official board of examiners, after a written public examination.

DR. THOMAS H. FENTON, of Philadelphia, spoke on

HYGIENE IN THE PUBLIC SCHOOLS,

in which he presented the following indictment. The locations of buildings were often on small streets; the houses crowded closely together; the ventilation was poor, or *nil;* the drainage bad; the illumination poor, and not managed according to the best scientific principles; the hours of study too long, and the hours of play too short.

DR. ALICE BENNETT, of Montgomery Co., then delivered the *Address on Mental Disorders,* and choose for her subject,

THE RELATION OF HEART DISEASE TO INSANITY.

The physiological mode of action of brain- and nerve-cells being utterly unknown to us, the manner in which such action may be modified can be but a matter of conjecture. But it is not unreasonable to suppose that irregularities of the circulation, such as are common in organic heart disease, may have an influence in modifying the action of an organ so peculiarly open to impressions as the brain, and whose anatomical connections with the heart are direct and intimate.

Of 500 cases examined in the female department of the Hospital for the Insane at Norristown, taken without discrimination, there were found 101 abnormal hearts, classified as follows: simple irregularity, 11; hypertrophy and dilation, 4; apex systolic murmur, 70; with basal systolic, 16.

Feeble action of the heart was noted among the advanced dements. There was also a very general absence of hæmic murmur. But it is to the coincidence of heart disease with a certain form of chronic mania to which this paper is specially designed to call attention. The histories of sixteen cases possessing similar features, and all presenting evidence of mitral disease, were then given. These cases constitute a distinctive class, easily recognized by the merest novice.

Some of the general features are as follows: They begin generally in middle life. The invasion is gradual, generally ascribed to no cause, or to one obviously inadequate. The first symptoms are invariably hallucinations of one or more senses, generally of hearing, and subsequent delusions of persecutions.

Among this class we find some of the most quiet inmates of our hospitals; some, not obviously insane to casual observation, who have remained in stationary conditions for years; others, beginning in the same way, show a tendency progressing toward a general misconception of all the facts of their daily life. In four of the cases delusions as to identity were present.

Another series of twenty-four cases present salient features characteristic of this class, although not so typical and unmixed as those given above. All have hallucinations of hearing, and all have disease of the heart, generally mitral insufficiency.

Of the forty-seven cases of chronic mania found to have heart disease, forty are mentioned above; of the remaining seven, two began as violent acute mania; three are of a recurrent type, consisting of paroxysms with general incoherence and mixed delusions; one is of unknown history and has delusions relating to wealth. In none are hallucinations known to be present. It is only fair to look at the one hundred and one cases of chronic mania showing no cardiac disease. The list comprises a great variety of conditions. A number began as violent acute attacks that have never recovered. These show all kinds of delusions; generally changing and transitory, and there are some hypochondrical and hysterical cases; a number are traced to the use of alcohol. Very many have an unknown history.

A careful examination of the whole number shows only three cases which bear any resemblance to those given above. One of these is deformed by disease of the spine; she has made homicidal threats in consequence of supposed injuries. One has progressing phthisis, and her insanity was attributed to alcohol; of the third nothing is known except that she goes about beating the walls with her shoes, probably under the influence of hallucinations.

It is not my intention to draw any inference from the above cases, which I do not offer as anything more than a rather remarkable series of coincidences. It has only been shown that among five hundred patients, a certain distinctive form of mania has been found, almost without exception, associated with valvular disease of the heart, generally mitral. Whether the "frequency of the coincidence" justifies the suspicion of a causal relation, is for you to determine. Admitting the suspicion, it must be verified, or the reverse, by continued observations.

DR. R. N. CHASE, of Montgomery County, then read a paper entitled

THE PROTECTIVE RIGHTS OF THE INSANE IN PENNSYLVANIA.

He contrasted the old and barbarous system of abuse

with our present treatment. He ascribed the first movement of reform to Tuke, in 1792, and traced it up to the present time. He reviewed the laws regulating the visits of boards and friends of the patient; explained that patients confined must be supplied with materials for writing to friends and relatives; that notices of the rights of patients should be posted in such places as could be easily seen and read by them; that their letters must be sent promptly, or the reason for failure written on outside of envelope, and that under no pretence was a letter to the patient's attorney or to the Board of Lunacy to be delayed; that abuses by those in charge should be dealt with according to law; that the beds, food, etc., were under the inspection of the Board; that reports on deaths, escapes, etc., were rigidly reported; and, lastly, that in no State or country were the rights of the insane better protected than in Pennsylvania.

DR. J. B. ROBERTS, of Philadelphia, offered a resolution that the Nominating Committee appoint a committee of seven to secure a charter for

A NEW MEDICAL COLLEGE,

to be known as the Pennsylvania Medical College, and to be situated in either Philadelphia or Allegheny County. Said college to have a preliminary examination, and a graded course of three years. Said college to be put in operation only on the condition that the present colleges do not adopt a preliminary examination by that time. This resolution was laid over.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—E. P. Allen, M. D., of Bradford.

Vice-Presidents.—Drs. Jacob Price, of West Chester; D. W. Bland, of Pottsville; C. Brandes, of Erie; and S. R. Rutledge, of Blairsville.

Permanent Secretary.—Dr. W. B. Atkinson, of Phila.

Recording Secretary.—Dr. A. J. Cornell, of Lackawanna.

Corresponding Secretary.—Dr. John G. Lee, of Phila.

Treasurer.—Dr. Benjamin Lee, of Philadelphia.

Committee on Publication.—Drs. R. J. Dunglison, H. Leffmann, of Phila., and E. Jackson, of West Chester.

Judicial Council.—Drs. Traill Green, of Easton, J. A. Ehler, of Lancaster, and W. T. Bishop.

Next Place of Meeting.—Scranton. *Time.*—Second Wednesday in May, 1885.

Chairman of Committee of Arrangements.—Dr. J. F. Everhart. Associates to be chosen by the Lackawanna County Society.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

YELLOW FEVER NOTES.—Sanitary Inspector Burgess, U. S. M. H. S., reports from Havana that there were 490 deaths in that city during the month of April, 34 of which were from yellow fever, 11 from typhoid fever, and 17 from pernicious fever. Of the 34 deaths from yellow fever, 18 occurred in the military hospital, and the remaining 16 in civil circles. Thirteen deaths from yellow fever are reported by him as having occurred during the first week in May.

Surgeon Murray, U. S. M. H. S., in charge of Ship Island quarantine, reports the arrival and disinfection of one vessel each from Rio and Colon, the latter with a clean bill of health.

The Secretary of State has received information, through the consulate at Maracaibo, that the reported epidemic of yellow fever at Cucula, Venezuela, in which it was stated that 1170 deaths occurred in a few days, is incorrect, an investigation made into the facts showing but 126 deaths in four months from this disease.

LONDON.

(*From our Special Correspondent.*)

TUBERCULAR TUMORS OF THE LARYNX.—At the meeting of the Clinical Society of London held on Friday, April 18th, DR. PERCY KIDD read a paper on tubercular tumors of the larynx. When the patient was first seen the signs of pulmonary mischief were but ill-defined; the laryngeal symptoms were predominant. It is needless to go into the details of this most interesting case; the main feature was the presence of *tumors* in the larynx of undoubtedly tubercular structure; moreover, notwithstanding the great tendency of tubercular formations to undergo caseation and ulceration, the growths in question remained as tumors for a period of no less than nine months. Dr. Percy Kidd discovered the characteristic bacilli in the laryngeal growths.

SIR ANDREW CLARK suggested that a fibrous degeneration of the tubercles might have prevented the development of ulcers, but Dr. Kidd said there was no appearance of fibroid tissue which would justify that opinion. The size of the tumors was about that of a pea; their situation was about the processus vocales. Schnitzler, it appeared, had described a similar case; but, with that exception, Dr. Kidd had searched literature in vain. Since his paper was written, however, he had met with two somewhat similar cases, in which the larynx was the seat of tubercular tumors, but the delay in ulceration was by no means so great.

EXCISION OF THE RECTUM FOR EPITHELIOMA.—The paper on this subject, by MR. HARRISON CRIPPS, excited considerable discussion. The general opinion of the surgeons was to the effect that operation for rectal cancer was decidedly to be recommended. Differences, of course, were mentioned in the modes of procedure.

MR. WALSHAM preferred to use the scissors, and considered that, even though the total extirpation of the disease could not be practised, yet the removal of as much as possible was a good procedure. Contraction of the calibre of the rectum and incontinence of feces were no doubt the great troubles which the surgeon had to contend with after the operation.

MR. BARKER thought that where the entire circumference of the rectum was not taken away, the result was better; for, as in an instance quoted, although the contraction might seem as great, yet practically the obstruction was much less, owing to the slight preservation of normal rectum. It appeared that a valvular arrangement was produced by the retention of a portion of the circumference of the normal rectum.

SIR ANDREW CLARK said that in his experience

cancer of the rectum was not so rapidly fatal a disease as text-books would have us believe. He spoke of a case which had lasted for eight years.

MR. HARRISON CRIPPS did not agree with Sir Andrew's observation, but he mentioned that in one of the cases on which he had operated the patient was alive eight years after the surgical treatment.

MR. RICKMAN GODLEE advocated the use of Pacquelin's cautery. He also referred to a case in which repeated scraping seemed to have prolonged life.

TUBERCULAR MENINGITIS.—DR. ANGEL MONEY reported the case of a female infant, aged nine months, who had a "fit," followed by hemiplegia of the left side, one month before she was first seen. There were no other signs or symptoms of disease except the hemiplegia at this period. The baby was extremely fat. Two or three weeks later the "fits" recurred, the breathing became changed in rhythm, and on the last day of life the temperature rose to 107.7°. The presence of ankle clonus was mentioned as interesting. At the autopsy there was a great amount of disease in the form of tubercular meningitis. The cause of the hemiplegia was, however, thrombosis of a large branch of the right middle cerebral artery. This thrombosis might have been produced by the meningitis, or might have been the result of embolism, seeing that Dr. Angel Money discovered a duckweed-like growth on the smaller flap of the mitral valve. The other organs of the body gave evidence of a general tuberculosis.

In the discussion of this subject, Drs. Glover, Heron, and Tonge Smith referred to cases of evanescent paralysis.

ASSOCIATION OF MEDICAL SUPERINTENDENTS OF AMERICAN INSTITUTIONS FOR THE INSANE.—The thirty-eighth annual meeting of this Association was held at the Continental Hotel, in the city of Philadelphia, commencing on Tuesday, May 13, 1884.

The following addresses, commemorative of the Fortieth Anniversary of the Association, were delivered.

History of the Association and its Necrology, by Dr. John Curwen.

Causes of Insanity in America, by Dr. G. A. Shurtleff.

Progress in the Treatment of the Insane, by Dr. H. P. Stearns.

Progress in Provision for the Insane, by Dr. W. W. Godding.

Progress in the Pathology of Insanity, by Dr. Daniel Clark.

MEDICAL SOCIETY OF NEW JERSEY.—The next annual meeting of the Medical Society of New Jersey will be held in the Stockton House, at Cape May City, on Tuesday and Wednesday, June 10 and 11, 1884. The address by the President, Dr. J. Wicks, will be delivered Tuesday evening. A complimentary train, for the physicians and their families, will leave Camden for Cape May on Tuesday at 12 o'clock M.

COLLEGE OF PHYSICIANS AND SURGEONS OF NEW YORK.—At the seventy-seventh annual commencement of the College of Physicians and Surgeons of New York, held on May 13, the degree of M.D. was conferred upon one hundred and five graduates. The Alumni prize of five hundred dollars was awarded to Dr. M. Allen Starr, of New York.

ILLINOIS STATE MEDICAL SOCIETY.—The thirty-fourth annual session of this Society will convene in Chicago on May 20th.

COLUMBUS MEDICAL COLLEGE.—The annual commencement of this school was held on March 7th. Diplomas were conferred upon thirty-five candidates.

STARLING MEDICAL COLLEGE.—At the thirty-seventh annual commencement of this school, held on March 5th, twenty-five candidates received the degree of M.D.

TRICHINOSIS IN GERMANY.—It is officially stated that last year, at Ermsleben, a small town of Prussian Saxony, four hundred and three persons were seriously ill, and sixty-six died from trichinosis. The disease was caused by eating raw pork, which all came from one hog.

ACTION OF THE FACULTY OF JEFFERSON MEDICAL COLLEGE ON THE DEATH OF PROF. S. D. GROSS.—

THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.
Thursday, May 8, 1884

The Faculty have learned with profound sorrow the death of their late colleague, the Emeritus Professor of Surgery, Dr. Samuel D. Gross. First as a student within its precincts, and afterwards its most eminent professor, his career constitutes one of the chief glories of this College. He was alike distinguished in all the fields of intellectual activity open to the medical profession. As a practitioner of surgical art, as a teacher and professor of surgery, and as author of a great surgical treatise, he stood in the front rank of the world's great men devoted to these pursuits. Whilst we thus do homage to his mental powers, we are not less appreciative of those admirable personal traits and social gifts by reason of which he endeared himself to the whole body of the medical profession.

We offer to his family our sincerest condolences on their irreparable loss. In testimony of the reverence in which we hold his memory, we cause this memento of our grief to be entered on the minutes of the Faculty, and it is hereby ordered that the large painting of the deceased Professor, now in the Faculty-room, be draped in mourning.

By the Faculty,
ROBERTS BARTHOLOW, M.D.,
Dean.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 6 TO MAY 12, 1884.

WEBSTER, WARREN, *Major and Surgeon.*—Granted leave of absence for six months, from April 29, 1884, on account of sickness.—*Par. 5, S. O. 103, A. G. O.*, May 3, 1884.

STERNBERG, GEORGE M., *Major and Surgeon.*—Now at Governor's Island, New York harbor, ordered to repair to this city (Washington, D. C.), to represent the Medical Department of the army at the annual meeting of the American Medical Association, to meet on May 5, 1884, and, on adjournment of the Association, to return to Governor's Island.—*Par. 2, S. O. 103, A. G. O.*, May 3, 1884.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLIV. SATURDAY, MAY 24, 1884. NO. 21.

ORIGINAL ARTICLES.

LACERATIONS OF THE FEMALE SEXUAL ORGANS CONSEQUENT UPON PARTURITION;

THEIR CAUSES AND THEIR PREVENTION.[1]

BY S. D. GROSS, M.D., LL.D., D.C.L. OXON., LL.D. CANTAB.,

EMERITUS PROFESSOR OF SURGERY IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

My object in appearing before you, as stated in the programme, is to read a paper on lacerations of the female sexual organs consequent upon parturition. It may seem odd, if not impertinent, to those of you who do not know me intimately, that I should venture to discourse upon such a subject so essentially in the hands of specialists; but they will perhaps pardon me if I tell them that, although I have all my professional life, now extending over a period of fifty-six years, been a general practitioner, yet during the first third of a century of that life I was more or less extensively engaged in obstetric practice; while during the last third I have had more or less to do almost daily with the treatment of female diseases requiring the use of the speculum and operative interference of various kinds. I have performed ovariotomy, and on numerous occasions sutured the perineum and the vesico-vaginal septum with a degree of success, if not highly flattering, at all events respectable. Within a short time after my entrance into the profession, I translated Hatin's *Manual of Obstetrics*, a small volume which had an extensive circulation in its new dress; in 1839 I contributed several pages in my work on *Pathological Anatomy* on "Uterine Moles," founded upon original observations and dissections; and in 1854 I unearthed, after much labor and research, Ephraim McDowell's claims to the fathership of ovariotomy, up to that period generally ascribed to other sources. Moreover, as a writer on systematic surgery, compelled to keep abreast with the knowledge of the times, I have embodied in my treatise an elaborate chapter on the diseases and injuries incident to the genital organs of the female sex, reflecting, at least in some degree, an outline of the existing state of the science. I make these remarks, in anticipation, as a justification for bringing before the Section a subject which, in some of its relations, has been so often and so elaborately discussed by many of the ablest men all over the civilized world. I might have taken my budget before the Surgical Section, but believing that fairer justice would be meted out to it here, I have given it this direction. When I shall have finished my task I trust you may not be able to say with Appeles, "Ne sutor ultra crepidam;" but rather incline to Tacitus, "Nihil scriptum miracuti causa."

It is astonishing how much has been written on the treatment of these lesions, and how little has been said upon their causes and prevention. Operations almost innumerable have been devised for their relief; volumes have been written upon the subject, and everywhere, in town and city, the gynecologist is ready to offer his services in sewing up lacerations of the genital organs of maltreated and unfortunate women. Seldom do we hear the voice of any of them raised in behalf of preventive measures, and then only in an indirect or roundabout manner. I am here this evening, not to wrestle with shadows or imaginary demons, but with stern realities, and to speak the truth, the whole truth, and nothing but the truth, as I understand it. The time has arrived when this matter should be met in a bold and fearless manner.

The lacerations of which I desire to speak are those which affect—(1) the perineum; (2) the vesico-vaginal septum; (3) the recto-vaginal septum; (4) the neck of the womb; and (5) the urethra, or mouth of the urethra and of the vagina. A few remarks under each of these heads will suffice for my purpose.

Laceration of the perineum is of frequent occurrence, and cannot always be avoided even under the most judicious management. In primiparæ, the fourchette is almost invariably ruptured, especially when the tissues are unusually rigid, and the protruding structures are very large, or very rapid in their descent, or where the perineum is not properly supported. Fortunately, such an occurrence is of little moment, as it respects the patient's welfare, either present or prospective. But it is very different when the rupture is extensive, involving a large portion of the perineum, or perhaps extending—as not infrequently happens—through the sphincter muscles of the anus and the lower extremity of the vagina. Then such an accident constitutes a great evil, and demands more or less skill for its cure.

Lacerations of the vesico-vaginal septum are among the saddest of calamities, entailing, if not successfully remedied, endless suffering upon the poor patient. I know of nothing more calculated to excite our sympathy, or to enlist the noblest qualities of our nature. In the worst forms of such accidents, in which science and skill offer no relief, as occasionally happens even in these enlightened days, death would be a welcome visitor. Equally distressing is a recto-vaginal fistule, or a rent with loss of substance in the urethra.

Lacerations of the neck of the uterus, even when comparatively slight, often entail great suffering, local and constitutional; the former manifesting themselves in various kinds of pains and discharges, and the latter in almost every form of nervous dis-

[1] Read before the Section on Obstetrics and Diseases of Women, American Medical Association, May 8, 1884.

orders of which it is possible to form any conception, together with more or less derangement of the digestive and assimilative organs. Of the frequency of these accidents, an idea may be formed when I state, what has long been known to most of you, that one of our most distinguished native writers on gynecology has expressed his conviction that rupture of the neck of the uterus, in greater or less degree, is almost inseparable from a first labor. Whether Dr. Emmet is correct in this conclusion, is a question which remains to be determined. If it be true, it would inevitably go to prove that God has made woman much less perfect than the world has given him credit for. As childbirth is one of the special prerogatives of woman, designed to perpetuate the race, there is something peculiarly distressing in such an idea. Looking at the matter from a practical standpoint, one would naturally conclude that the Author of our being had constructed the womb with special care to protect the organ, at least as a rule, against the possibility of a contingency fraught with such sad consequences. If we assume the correctness of Dr. Emmet's statement, we may well wonder, without irreverence, why Almighty God did not create simultaneously with woman a competent gynecologist, ready to meet this inevitable evil, for such unquestionably it must be whenever it occurs. If this evil is the outgrowth of civilization, then the sooner we get rid of this civilization the better will it be for our poor wives and daughters, considered as procreating beings.

It was a happy circumstance when, in 1851, Sir James Y. Simpson first called attention to this important subject. It was like the discovery of a new world in human progress. In the *Proceedings of the Edinburgh Obstetrical Society*, for January of that year, he proclaims the important truth, until then unknown, or only guessed at, that fissuring and laceration of the cervix are not, as had been generally believed, rare lesions during labor, but, on the contrary, very common occurrences, especially in primiparæ, and he supports his views, not only by what he saw with the aid of the speculum, but by an appeal to autopsies in which rents and fissures were detected in the mouth and neck of the uterus after natural labor. The facts thus pointed out by the great Scotch professor were afterwards—namely, in 1869, and again in 1874—brought more fully before the profession by Dr. Emmet, in two important papers published in the *American Journal of Obstetrics*, where they soon attracted general attention. To these two distinguished men, then, are we mainly indebted for the knowledge which we now possess upon this important subject; knowledge of priceless value to suffering woman, and of the greatest consequence to the obstetric practitioner.

If we inquire into the exciting *causes* of these accidents, it will be found that they vary with the situation and structure of the parts involved in them. The great factor in laceration of the perineum is parturition, either alone or in conjunction with the means employed to effect it. When this wall to the outlet of the pelvis is very rigid, and the action of the uterus unusually vigorous, forcing down the head of the child with great vehemence, it is easy to conceive not only of the possibility, but of the great likelihood of such an accident, especially in the absence of proper support. In such a condition the perineum is very much, to use a figurative expression, in the position of the door of a room, with a big, burly fellow on the inside, knocking for egress. To carry out the simile, he does not in every case batter down the whole of the opposing obstacle, but only a portion of it, representing a comparatively slight laceration, as where the fissure is limited to the fourchette, or to the anterior portion of the perineum, while, when the resistance is extreme, the entire wall is torn, the lesion extending, through the sphincter muscles, into the rectum; in other words, the entire door is battered down, and the vagina and bowel are laid completely open.

Of the various kinds of lacerations of the vagina, or of the vagina and the uterus, constituting what are known as fistules of the bladder, or of the rectum, those dire calamities which form so prolific a field for operative interference, the most common factor unquestionably is either prolonged or very severe pressure. "This is," says Thomas, in his able work, "beyond all doubt, the most prolific source of the accident, though it may also attend a rapid labor in which the vagina has been pressed against some point of the pelvis with great violence." The active agent of this pressure is generally the child's head, especially when it is disproportionately large or wedged in behind the pubic symphysis, unduly compressing the vesico-vaginal septum, followed by destructive inflammation and sloughing. The accident is generally the result of protracted pressure, as when the child's head has been wedged in in this position for many hours, neither, perhaps, receding nor advancing; or it may be caused in a very short time, as when the pressure is unusually concentrated and severe. If the pains are very violent, the pressure of the presenting parts may be so great as to end in actual rupture of the vesico-vaginal septum, but, as a rule, the opening is the direct result of concentrated pressure, eventuating in inflammation and sloughing, precisely as in an ordinary bedsore. Vesico-vaginal fistules are not infrequently produced by the pressure of the child's head upon a distended bladder. How far the maladroit use of the forceps, vectis, or other instruments may be capable of producing such lesions will form the subject of future inquiry.

The principal causes of lacerations of the cervix are precipitate labor, labor attended with rigidity of the mouth of the womb, and instrumental labor. Lacerations are not uncommon in breech cases, in which delivery is obliged to be expedited on account of the retained head before the cervix is properly dilated. These are unquestionably the most frequent and efficient factors in the production of accidents in this situation. If to these we add the presence of cicatricial tissue in the cervix, malpresentations, and section of the cervix, as occasionally practised by ignorant obstetricians, we have a complete list of all the causes, active and

predisposing, of rupture of the uterus during normal parturition. A premature discharge of the amniotic fluid acts mainly, I presume, as a means of retarding labor than as a cause of laceration of the cervix. I must not omit to allude here to a statement of Dr. Emmet that laceration of the cervix is of frequent, if not common, occurrence in cases of criminal abortion. I do not know that this fact has been noticed or verified by other observers, but of its truth I entertain no doubt. In his tables, Dr. Emmet gives ten cases of this kind, and he declares that he has met with this accident in every instance where the woman admitted the fact of exposure to malpractice.

Having thus briefly discussed the situation and causes of the accidents in question, let us, in the next place, inquire into the best means of preventing them, the chief object which I have had in view in bringing this matter before you to-day. There is more honor in one ounce of preventive midwifery than in one pound of curative gynecology, the outgrowth of ignorant or meddlesome obstetric practice. That many of these occurrences are inevitable without any just blame attaching to the professional attendant is well known to every practitioner of the least experience, but that they may, as a rule, be prevented by the exercise of proper care and skill will, I think, be readily admitted; at all events it is true.

The great remedy, as laid down in the books, for rigidity of the perineum is manual support during the descent of the child's head, or whatever else the presenting parts may be; this, as a rule, is quite sufficient; but not so when the resistance is very great. In this event, the accoucheur is expected to make use of the hot bath and of hot fomentations, to anoint the parts with oil, and even, in extreme cases, to make slight incisions on each side of the middle line. Nothing is said in these injunctions of the abstraction of blood as a means of relaxing this tense, resisting wall which so obstinately stands in the way of the completion of the parturient process. What are the active agents of this resistance? Unquestionably the muscles of the perineum, the sphincters of the vagina and anus, the transverse muscles, and the elevator muscles of the anus. The skin and connective tissue offer no obstacle. The whole difficulty resides in the muscles, and its amount is precisely in proportion to their development, great in strong, young, robust women, and comparatively slight in those of an opposite character. If this statement be correct, and no one can doubt it, it follows, as a necessary corollary, that the obstacle is most readily overcome by some measure that will relax the perineal muscles. Hot water, oil, and medicated unguents will not do this, and no sane man would wait for the tardy and uncertain effects of local bleeding. A far better plan is to take blood at once from the arm from a free orifice in one of the large veins, the patient sitting up in bed during the operation, so as to produce the most rapid and decided impression at the least expense of the system. If there be anything better than this, anything more likely to answer the purpose, I am not aware of it. The loss of ten, twelve, sixteen, or even twenty ounces of blood can do no harm in such a condition of things. A few days under proper treatment always suffice to replace it, while, as a rule, it promotes rather than retards recovery, by rendering the woman less liable to puerperal fever, peritonitis, and pelvic cellulitis.

In regard to lacerations of the vesico-vaginal septum, much may be done in the way of prevention, and so also in regard to rents into the rectum. It is self-evident that anything that lessens the size of the canal through which the child is to pass, or that seriously interferes with the descent of the child's head, must act as an impediment to delivery. All obstetric teachers are aware of this fact, and hence they take special pains to instruct the young practitioner to see that the rectum is well emptied during the later stages of pregnancy, or, at all events, on the approach of labor, and that the urine is evacuated from time to time as the labor progresses. These precautions are unquestionably most important safeguards, and, if duly attended to, are rarely followed by serious injury. If, on the contrary, they are neglected, as I fear is not infrequently the case, especially among the lower classes of women, it is easy to conceive that the consequences must be of the most direful nature, especially if, superadded to these obstacles, there is an impacted condition of the child's head along with violent uterine contraction. Under such circumstances it is difficult to conceive how the poor patient could escape injury in some form or other. The machinery must break down somewhere. A few hours may suffice to do the mischief. The only remedy, of course, is the forceps or crotchet, and the former cannot be applied too soon. The bladder must be liberated, or a vesico-vaginal opening, if not something worse, will be the inevitable result.

The proper remedy for the relief of the stationary head, whether impacted or simply arrested by the inertia of the womb, is—provided the cervix is sufficiently dilated, or dilatable—the forceps, that "noble instrument," as it was called by Chapman, who, in 1733, published the first account of it, upwards of one hundred years after its invention by Paul Chamberlen, of England. I shall not speak of the numerous modifications which this valuable instrument has experienced in the hands of the obstetricians, or detain you by asking whether the long instrument is preferable to the short, or the short to the long. In the hands of the judicious practitioner, each has a distinct and separate value; but it will be pertinent to the object of this paper to inquire into the reasons which have led to the great changes which have taken place in regard to the frequency of its use.

Beginning with the great Baudelocque, the most illustrious accoucheur of the last century, we find that he applied the forceps once in 561 cases; Clark in 728; Collins in 617; Lachapelle in 293; Baer in 274; Boivin in 214; Davies in 53; Naegle in 31; Kluge in 16; Carus in 14, and Siebold in 7.[1] Smellie, who flourished in the middle of the last century, and who was the most famous accoucheur

[1] Robert Lee's Table, in Lectures on Midwifery.

in his day in Great Britain, applied the forceps once in 125 labors; and Merriman, another distinguished English obstetrician, once in 93.

From the late Dr. Churchill, of Dublin, we learn that in Great Britain, until recently, the forceps were employed once in 249 cases; in France, in 140; and in Germany, in 106.

In this country, the present fashion is to apply the forceps very frequently, both in private and in hospital practice. Some of my friends inform me that some accoucheurs resort to the instrument as often as once in 4 labors; others in 6, 8, or 10. Whether the forceps are employed as often in Great Britain and on the Continent of Europe, I am unable to say; but the difference, if any, must be very trifling.

Dr. William P. Dewees, who was the great Philadelphia accoucheur in his day, and who delivered upwards of ten thousand women, writing in 1843, holds the following language in regard to the use of the forceps: "However strongly I may be impressed with the utility of the forceps, I should not feel myself warranted to use them as often as they appear to be in Great Britain and on the Continent of Europe. The frequency with which they have been employed in some instances is really alarming, and, I had like to have said, must have been too often unnecessary. In my own proper practice, I have not employed them oftener than once in three hundred and fifty cases, though I have been under the necessity of using them very frequently in the practice of others."[1]

Notwithstanding that Dewees so seldom employed the forceps in his own cases, we nowhere find that he had any serious lacerations of the genital organs. In the tenth edition of his *Treatise on the Diseases of Females*, published in 1854, "with the author's latest improvements and corrections," not one word is said upon the subject, not even upon rupture of the perineum. Now, if such accidents had occurred under his observation he could hardly have failed at least to mention the fact. If I am told that Dewees did not use the speculum, and could, therefore, not detect them, I reply that he had eyes to see, and fingers to feel. He certainly could tell what the nature of the case was when urine or fecal matter flowed off by the vagina. Philadelphia's great accoucheur, Dr. Ellwood Wilson, has superintended, as he informs me, 10,600 cases of labor at the Lying-in Hospital in that city, without the occurrence of a solitary instance of vesico-vaginal, or recto-vaginal fistule. He, like others engaged in large private practice, has witnessed numerous atrocities in consultations. The testimony of my late colleague, Professor Ellerslie Wallace, is precisely of the same import.

In a discussion of the admirable paper of Dr. Emmet, "On the Necessity for Early Delivery, as demonstrated by the Analysis of 161 Cases of Vesico-vaginal Fistula," read before the American Gynecological Society, in 1878, Dr. D. Humphrey Storer declared that, in an experience of several thousand cases of midwifery, he had witnessed only two cases of vesico-vaginal fistule, adding that there was no man in Boston who applied the forceps less seldom than he. He approved of the employment of the forceps in certain conditions of labor, "but the idea," he remarks, "that the forceps is an instrument which must be almost constantly used is, I think, a dangerous one." This sentiment was elicited by the statement of Dr. Emmet that the great factor in the production of vesico-vaginal fistule is impaction and long detention of the child's head, aided by distention of the bladder, and the assertion that instrumental delivery has rarely, if ever, any agency in the production of this sad occurrence.

Dr. H. P. C. Wilson, of Baltimore, on the same occasion, asserted that he had made it a rule for many years, when called to a case of labor, to carry with him a bottle of chloroform and a pair of forceps, adding that he had frequently used the forceps when he was certain that the woman would be delivered safely by nature, simply to shorten the labor and relieve suffering. Dr. John L. Atlee, in referring to Dr. Wilson, said, "the older I grow the more apt I am to employ the forceps." In opposition to these sentiments, I take leave to cite the views of America's latest writer on obstetric medicine, Dr. Lusk, as expressed in his admirable treatise, *The Science and Art of Midwifery*, the second edition of which was issued only a few months ago. "I can only say," declares this excellent author, "that, with increasing experience, my own practice has grown more and more conservative, and my own belief is that true wisdom requires us to abstain from even trivial operations, so long as nature is able to do her work without our assistance."

Is it not a fact, I would ask, that the forceps are often used merely as a means rather to save the time of the accoucheur, than as a means to prevent the suffering of the poor woman; to enable him to meet another engagement, to visit the theatre, or to attend a dinner or an evening entertainment? Passing along the streets not long ago, said Dr. Goodell to me a few months since, my eye lighted upon a gentleman walking rapidly on the opposite side, who, the moment he recognized me, shook his green bag at me, exclaiming, "reed birds for supper," and hurried on.

I take leave here to quote what I deem eminently pertinent to this part of my paper, a passage from a communication that appeared in the New York *Medical Record*, March 8th, of the present year, from the pen of Dr. A. E. Dugas, of Augusta, Georgia: "When I graduated in 1875, an old sage in the profession advised me as follows: 'My boy,' said he, 'I am an old man; I have practised over fifty years, and, as you are aware, have been very successful. In regard to your labor cases, I would give you the following advice: First, as you intend practising in the city, make it a habit of leaving your forceps at your office, for, if you ever require them, you will always have ample time to send for them, and your not having them with you may save some women much trouble. Second, do not examine your patient much or often; see that

[1] Midwifery, p. 272.

things are right, and then let nature manage the case.'"

The "old man" here alluded to is no less a personage than the great and venerable Dr. Louis Alexander Dugas, a man of vast experience as a practical surgeon and accoucheur, and emphatically one of the sages of our profession. How wise such advice is in contrast with the accursed practice of the day, when every obstetrical fledgling thinks himself competent to use the forceps, and is anxious to get to his "reed-bird supper," I leave you to judge.

If all accoucheurs were well educated and well versed in the use of the forceps, there might be some justification for the frequency with which they are applied at the present day. There might even be some justification in hitching them on the child's head, when nature is fully equal to her task, to get home in time to a good supper; but to use them on the slightest pretence, as is so often done now-a-days by every sciolist, hardly out of his swaddling clothes, is, if you will allow me to say it, simply damnable. Surely our obstetric teachers have a great deal to answer for in sending forth every year armies of incompetent young accoucheurs. Surely they commit a grave sin when they teach the frequent application of this "noble instrument," employed far too seldom in former times, as it is certainly employed too often in ours. In conversing recently upon this subject with a distinguished obstetric teacher, now retired, he said to me, "I always enjoined it upon my pupils, after pointing out to them the uses and abuses of the forceps, to carry the instrument with them to every case of labor, adding that it was just as important as it is for the mariner to carry his compass with him to sea." Without wishing to disparage the judicious use of the forceps, which I have no right to do, and which God forbid I should do, I think a careful consideration of the case justifies me in endorsing the opinion of Baudelocque, uttered more than a century ago, that the forceps, as generally used, have done more harm than good, and in this view I am glad to be able to say that I am sustained by many eminent, able, and experienced obstetricians and gynecologists of the present day.

That many accidents happen for the want of a proper use of the forceps, or of their timely application, is proved by the numerous cases of vesico-vaginal and other fistules, and by the still not infrequent sacrifice of the child, if not also of the mother; of the former by fatal compression or craniotomy, and of the latter by exhaustion, heart clot, pulmonary obstruction, or other causes. It would be difficult to find in all the records of obstetric medicine a case which more sadly and forcibly illustrates the baneful effects of the want of the proper use of the forceps than that of the Princess Charlotte, whose death, in 1817, threw the whole British nation into mourning. The amniotic liquor had been discharged early in the labor, and although the head had long been in the lower strait, the delivery, which took place at the end of fifty-two hours, was entrusted entirely to nature's efforts. No wonder that the child was still-born, and that the poor woman, exhausted by her protracted labor, expired soon after her delivery. No wonder that her principal accoucheur, Sir Richard Croft, committed suicide as the best remedy for his sad blunder and consequent mortification!

I come, in the third place, to inquire briefly into the proper preventive treatment of lacerations of the cervix. We have said that these injuries are most common, by far, in primiparæ, especially when pregnancy occurs in women somewhat advanced in life. Spiegelberg found that the average duration of labor in five hundred and six primiparæ was seventeen hours, and twelve hours for multiparæ. After the thirtieth year, the duration is materially increased, amounting, according to Hecker, in primiparæ, to twenty-one hours, and, according to Ahlfeld, to twenty-seven hours.[1] If we ask what is the cause of this difference in the duration of labor in primiparæ and multiparæ, we shall find a ready answer in the difference in the pliancy and softness of the genital organs, and in the fact that the way is paved by the previous parturition. In primiparæ, especially in elderly ones, the genital organs are hard, firm, inelastic, unyielding; in multiparæ, on the contrary, they are comparatively soft and dilatable, yielding readily before the advancing head. In the one case the labor is comparatively easy, rapid, and safe, both to mother and child; in the other, painful, protracted, and fraught with danger; the uterus and perineum, not to mention the vaginal septa, are liable to be torn, and the child often perishes from injury inflicted upon its head and lungs. If, in such a labor, delivery be attempted with the forceps before the parts are properly relaxed, or if attempts be made to dilate the parts forcibly with the fingers, it is easy to perceive that rupture, of a more or less serious nature, must inevitably happen.

Since the attention of accoucheurs was first directed to the frightful frequency of lacerations of the cervix in primiparæ by Simpson and Emmet, the subject has assumed a degree of importance previously undreamed of, and the question naturally arises here: How are these injuries to be avoided? How are we to abridge the duration of labor in primiparæ, and to place them on the same level with the multiparæ? There is but one way to accomplish the object, and that is by the employment of relaxing agents. It is a well-known fact that labor is more easy in hot than in cold climates, a circumstance which would naturally lead us to employ hot applications, as the hot bath, hot fomentations, and hot injections. I will not deny that such agents might occasionally do good, but what sense is there in parboiling a woman when we have at hand other agents far more speedy and more efficacious in their action. I do not allude here to chloral, ether, chloroform, and tartar emetic, the last of which, from its tendency to produce vomiting, could hardly in any case be a safe remedy, while the former, with some advantages, would seldom prove reliable to bring about the desired result. The great remedy which I have in my mind's eye is venesection, car-

[1] Lusk, Science and Art of Midwifery, p. 134. Second edition, 1884.

ried to a reasonable but sufficient extent to relax the system and through the system the genital organs. I do not introduce this as a new remedy, for general bleeding to overcome rigidity of the uterus and perineum was practised long ago, and is still practised by many of our older physicians under such circumstances; but I desire to recall attention to it as the most prompt, powerful, and efficacious of all the agents that the accoucheur can press into his service for the attainment of this end. I am not abashed if I am told, at the very threshold of this announcement, that venesection is an obsolete art, that none but old fogies would think of employing it, and that the blood during pregnancy undergoes such great changes as to render the loss of it, except in puerperal convulsions, an improper expedient during labor with a view of expediting it.

There was a time when this agent was very generally, I had almost said, universally used, even in my early days, in great rigidity of the sexual organs; fortunately, that day has gone by. But if the lancet was used too much then, it is certain, at least to my mind, that it is not used enough now. We are too apt, as a profession, to be influenced by prejudice, especially when it is backed by great authority. When the wether jumps the rest of the flock are sure to follow. I recollect when it was customary to bleed pregnant women for the relief of headache, dizziness, or vertigo, pulmonary congestion from aortic obstruction, and pelvic and sacro-lumbar pains. The "false pains," as they are termed, often so harassing and worrying as to be a source of real suffering, may generally be promptly relieved by the abstraction of eight, ten, or twelve ounces of blood; and who would not bleed, bleed freely, when a plethoric pregnant woman is threatened with convulsions? To withhold the lancet in such a condition would simply be criminal, and yet some obstetricians, even of world-wide renown, would content themselves with the exhibition, in such an event, of chloroform, of chloral hydrate, or of both articles combined.

If I be told that a pregnant woman should not be bled because, while in this condition, she experiences a marked decrease of the red corpuscles of the blood, I answer that this would be simply begging the question. If this were the only change which this fluid undergoes to meet the physiological necessities of the system during utero-gestation, there might be some reason for such a conclusion. But this is not the fact, for, while there is a marked diminution of red globules, there is also a marked increase of fibrin and albumen, assimilating the mass of this fluid to the condition in which it is found to be in inflammation. Instead, therefore, of using these changes as an argument against the use of the lancet, they afford the strongest possible evidence in favor of it whenever a powerful relaxant is required to facilitate parturition. May plethora not be caused by the presence in the blood of an undue proportion of its fibroid, albuminoid, and aqueous constituents? Blood is formed rapidly in pregnancy, to meet the demands of the system, and it is not at all necessary to perform experiments on bitches to prove what daily passes under our observation in the human subject. The great strength, the exuberant health, the florid cheek, and the genial warmth diffused throughout the entire system, sufficiently attest the presence of an active circulation, with an abundance of red globules, although they may be relatively fewer than in the non-pregnant state. No rational accoucheur would bleed an anæmic woman, or a woman laboring under cardiac disease, aortic insufficiency, chronic malarial fever, or any wasting malady whatever. Such affections point out their own remedies—supporting, and not depleting measures.

There is an idea, almost universally prevalent, that the people of the present day do not bear loss of blood as well as they did forty, or even twenty, years ago, an opinion which has exerted such an influence upon medical men, as well as upon the public at large, that venesection has become an obsolete operation, or an operation which is, at most, limited to a few old fogies—as they are sarcastically styled—ignorant of the benign progress of the healing art, and of the tolerance of the system. Whether this opinion be true or erroneous, this is not the time nor the place to inquire; suffice it to say that my solemn conviction is that the neglect into which this operation has fallen, not only in midwifery, but in general practice, is the cause, annually, of the loss of thousands upon thousands of human lives that might otherwise be saved.

If I were asked under what circumstances a pregnant woman, in sound health, without any complications, ought to be bled, I should answer, first, when she is threatened with abortion, miscarriage, or convulsions; secondly, when there is a rigid os, obstinately refusing to yield after the labor has been in progress for six, ten, or twelve hours; thirdly, as a rule, in tardy labor in primiparæ, especially after the age of thirty; fourthly, where there is, so to speak, rigidity of the general system, including, of course, the sexual organs; fifthly, when there is a decidedly feverish condition of the systen, associated with severe headache, great heat and dryness of the genital organs, a rigid os, or os and perineum, and inefficient, teasing labor-pains; and, lastly, in torpor of the uterus from the effects of inflammation, gout, or rheumatism, interfering with or retarding delivery. In all, or, certainly, in most of these conditions, I should follow up the effects of the bleeding with an anæsthetic, or a hypodermatic injection of morphia. I solemnly believe that, if these rules were properly observed, the process of parturition would be greatly facilitated, the pains of labor materially abridged, and the risks of lacerations, which now stand as such a blot upon obstetric practice, would be reduced to the merest minimum, not to say anything about the much greater safety of the child, and of the more rapid recovery of the mother.

As to the quantity of blood to be abstracted, every case must be met on its own merits. While in some instances the loss of a few ounces may suffice, in others, especially in strong, robust, plethoric women, sixteen, twenty, or even thirty may be required. Dr. Dewees, to whom is justly due whatever praise or blame attaches to this practice, occasionally bled to

the extent of forty ounces before he succeeded in overcoming the rigidity of the os. Sometimes, indeed, he carried the operation even to syncope; always placing the patient in the erect or semierect position, so as to expedite and increase the effect.

Dr. Dewees informs us that he was led to adopt the employment of general bleeding in midwifery, near the close of the last century, from having witnessed its beneficial effects in the practice of Dr. Physick, in relaxing the muscles in dislocations of the shoulder-joint.

Out of the injuries now considered, often unavoidable, but in the great majority of cases the effects of gross ignorance, timidity, indecision, or the maladroit use of the forceps and of other instruments, has grown gynecology, a twin sister of surgery, the scientific foundation of which was laid hardly thirty years ago by the immortal Sims, aided by Bozeman, Thomas, and Emmet, of America, by Baker Brown, of London, and by Gustav Simon, of Heidelberg, all pioneer laborers in this great field of the healing art, now trodden by many thousand feet, and illustrated by special treatises and contributions alike honorable to their respective authors and creditable to their respective countries.

IMPACTED FRACTURE OF FEMUR IN A WOMAN OF EIGHTY-FIVE YEARS; BONY UNION.

By D. S. LAMB, A.M., M.D.,
ARMY MEDICAL MUSEUM.

The healing of fractured bones in the aged is looked upon by most authorities in surgery as a result rather to be expected than not, especially if the fragments have been impacted, and have not been separated by the unwise interference of the medical attendant. Prof. Agnew supports this opinion by a case of fracture of the thigh bone at ninety-five years of age, in which bony union took place.

I take it, however, to be rare for the opportunity to be afforded to *verify* the seat and character of fracture and mode of union in patients of advanced age, by post-mortem examination, and as such an opportunity occurred to me a few months since, and the specimen has been preserved, I have thought that the clinical and post-mortem data might be of interest enough to place on record.

M. A., white, widow, had always been healthy, except that in her youth she was paralyzed in the right arm, and the paralysis became permanent. Her mind was in a condition of progressive imbecility at the time of the accident mentioned below. On the 4th of March, 1881, she attained her eighty-fifth year, and the same day, in descending the stairs, she missed the lowest step, and fell to the floor. She was at once placed in bed, but no serious trouble was suspected until two days later, when I was called. The left leg and foot were everted; there was shortening of about half an inch; no crepitus, but pain on moving the limb, and much resistance on attempting extension; there were swelling and ecchymoses in the trochanteric region. She was kept at rest as much as possible, but in the weakened condition of her mind she repeatedly forgot her injury and attempted to use the limb. On the 8th of March, Prof. Thomas B. Hood saw her, in consultation with me. Her age and mental weakness considered, neither of us expected union to take place. The better, however, to secure rest a starch bandage was applied and morphia given in small doses. A bedsore threatened to form, but was averted. There was no appreciable rise in the temperature, and her appetite continued good. In a month she sat up in bed—in a year walked without support. In the autumn of 1883 she began to lose appetite, flesh, and strength, and in October took to her bed. She died October 28th, nearly three years after the injury, and in her eighty-eighth year. Her imbecility had steadily increased.

Only a limited examination of the body was permitted, that of the head especially being forbidden. A rapid survey of the organs of the chest and abdomen showed no lesion other than a general atrophy. The left femur was removed and the surrounding soft parts examined; the arteries showed no atheroma or calcification. The bone, after maceration, presented the following appearances: Its general condition is good; length fifteen and one-quarter inches (one-half inch shortening); weight just eight ounces. The line of fracture extends diagonally through the great trochanter from the posterior inferior to the anterior superior angle, thence downwards a little external to the anterior intertrochanteric line to about one inch below the lesser trochanter, thence upwards and backwards, one inch external to the posterior intertrochanteric line, to place of beginning; the posterior portion of the neck is also impacted to the depth of one inch, the line extending from the lower outer angle of the neck upwards and backwards in front of the lesser trochanter into the digital fossa, so that while anteriorly the length of the neck is normal, posteriorly the curved margin of the head is just half an inch (instead of an inch and a half, as it should be) from the intertrochanteric line. The summit of the head is on a level with the upper border of the great trochanter.

MEDICAL PROGRESS.

Active Interference in the Management of Abortion.—A recent number of the *Zeitschrift für Geburts. und. Gynäk.* contains an article by Dr. H. Spoendly, of Zurich, on the above subject. The interference which he recommends is simply that, in every case of abortion, the medical attendant should take care that nothing is left in the uterus, should completely remove placenta and membranes; and that in every case of threatened abortion, in which the hemorrhage is profuse and does not yield to treatment, the uterus should be emptied as soon as possible. The expulsion of the placenta should not be left to nature. In this recommendation there is of course nothing novel, nor has Dr. Spöndly any new instrument or method of effecting the desired end. The main importance and interest of the paper is in the fact that the author gives a series of fifty-three cases in which he acted on the principles which he lays down, and with uniformly good results.—*Med. Times and Gaz.*, April 12, 1884.

CHOLECYSTECTOMY FOR GALL-STONES.—DR. THOMAS SAVAGE reports a case of this operation, performed in 1883. The patient was a man of sedentary habits, who for years had been conscious of the possession of a liver. He had consulted an eminent specialist for such cases, who told him that he had a hydatid tumor connected with the liver, and that it should be punctured by aspiration as soon as possible, proposing himself to do it. When I was consulted, I at once found the presence of the tumor, and said that it was probably hydatid, but that it would be better to perform an abdominal section, and treat the tumor in the best way that was thought advisable when it was exposed to view. It was put before the patient as being an operation not less safe than aspiration, and yet more likely to be curative. This plan was agreed upon, and fourteen stones, varying in size were removed.

The tumor was about the size of a medium coker-nut, and was, in fact, a distended gall-bladder. On tapping it, the first two-thirds of the fluid was transparent and colorless, and a little viscid; the latter one-third was bile-tinged, in fact, appeared to be pure bile. I very much regret that the fluid was thrown away in the confusion of putting straight after the operation. It has been suggested to me, in explanation of the presence of these two fluids in one sac, that the colorless fluid might have been indeed hydatid, and was kept distinct from the true bile by a wall formed of the stones, which, on the collapse of the gall-bladder by the escape of the clear fluid, broke down, and allowed the bile above it to escape also. The appearance of, and the facets upon, the stones pointed to their having been in close contact before their removal.

This case is interesting in itself, but also more on account of its showing the inutility of advising aspiration, when a tumor can be directly treated under one's eye and touch. Here aspiration would not have been of the slightest use, and might have done much damage. Indeed, it would have been more risky than an abdominal section, as bile might without difficulty have escaped into the peritoneum; and, as a matter of fact, Murchison and others have reported a goodly number of cases of tapping followed by a fatal issue.

To prevent the future recurrence and dropsy of the gall-bladder, Langenbuch, in 1883, has recommended extirpation of the gall-bladder. Three of such operations appear to have been successfully performed. Langenbuch advises to begin by detaching the gall-bladder from the liver, and to tie the cystic duct.—*British Medical Journal*, March 8, 1884.

THE RADICAL CURE OF HERNIA BY THE METHOD OF DISSECTION.—At a recent meeting of the Academy of Medicine in Ireland, MR. KENDAL FRANK read a paper on this subject. The only two methods which seemed to him to give promise of extensive application in the future were (1) suture of the abdominal openings without removal or ligature of the sac; and (2) suture of the abdominal openings after excision of the sac. The first of these operation was applied to recent hernia before the sac had time to become enlarged and thickened. The method consisted essentially in cutting down on the tumor, carefully exposing the sac which had been returned into the abdomen, and then drawing together the openings by means of two or three sutures of stout silver wire, which should be left permanently in position. He advised that the skin should be drawn slightly upwards before the first incision was made, as by that means the skin would not lie directly over the wires. Thus union by first intention was promoted, and the permanent retention of the silver wire assisted. Three cases were related in which this method was employed.

MR. W. THORNLEY STOKER said there were two distinct classes of cases: the class in which operation was compulsory, where strangulation existed, and the class where operation was a matter of election to promote the patient's convenience rather than to save his life. In nearly all cases of operation for femoral hernia, a permanent cure had been effected; but in large inguinal ruptures a radical cure was not so frequent, and, in such cases, the peritoneum should be sutured. In the second class of cases, he advocated Wood's operation. He did not think it mattered much whether the pillars of the ring were drawn together or not. A cure was effected by the inflammation exciting the exudation of coagulum and lymph, which drew the parts together, thereby closing the opening as with a cork. He protested against leaving in the wire suture where the ring was sutured in inguinal hernia, as most unscientific and unsurgeonlike, and a possible source of future trouble.

MR. W. L. WHEELER mentioned the result of nine cases in which he had operated by different methods. In a case of inguinal hernia, on the left side of a male, he exposed the neck of the sac. He then drew it down and applied a ligature, divided the neck, and removed the sac below the ligature. This case was successful when seen two years afterwards. In a femoral hernia, on the left side, in a female aged eighteen, he opened the sac, pulled down, excised, and closed the edges, and the result, eighteen months afterwards, was most satisfactory. In cases in which the canal was greatly distended by a large hernia it would be almost impossible to have a radical cure follow any radical measure, and the most likely method was excision of the sac.

DR. MCARDLE observed that it was almost impossible to bring the edges sufficiently close together to keep behind the sac, and that the irritation of the veins was likely to produce phlebitis.—*British Medical Journal*, March 8, 1884.

PRIMARY EXTIRPATION OF THE ASTRAGALUS IN CASES OF IRREDUCIBLE DISLOCATION.—In a lecture published by the *Rev. Méd. de l'Est*, February, 1884, WEISS strongly advises to perform the operation at once when the bone cannot be reduced. The absence of an external wound is no contraindication, as the mortality, which was estimated at twenty-seven per cent. by Broca, has been lessened very materially by the introduction of the antiseptic treatment. In the author's own case (a simple irreducible dislocation outwards, with much inversion of the foot) the operation was difficult, and the wound did not heal for a long time; but after a few months the patient began to walk, and the result appeared to be quite satisfactory.—*London Medical Record*, March, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE. . . . . $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,

SATURDAY, MAY 24, 1884.

RECENT VIEWS ON THE ORIGIN AND NATURE OF PNEUMONIA.

PERHAPS the most important subject considered at the recent Congress of German Physicians, sitting in Berlin, was pneumonia. The original paper was read by JUERGENSEN, of Tübingen, and the *confrère* to whom had been referred the consideration of the pneumonicoccus was FRAENKEL, of Berlin. The discussion was participated in by GERHARDT, of Würzburg, FRAENTZEL, of Berlin, RUEHLE, of Bonn, NOTHNAGEL, of Vienna, ROSENSTEIN, of Leyden, BAEUMLER, of Freiburg, and EDLEFSEN, of Kiel. At the same time, the results can scarcely be considered commensurate with the importance of the subject.

Within a few years past the views so long current as regards croupous pneumonia, that its cause is cold, its nature inflammatory, its initial symptom a chill, and its treatment antiphlogistic, have gradually given place in the minds of many to the idea that in croupous pneumonia we have an infectious disease. The natural difficulties in the way of substantiating such views have been diminished by the evidence which experimental pathology has furnished in the results of inoculation with the recently discovered micrococcus of pneumonia.

Closer examination has shown, too, that only four per cent. of the cases originate in exposure to cold, the remainder being doubtful or quite independent of it. Again, as to age, it was for a long time supposed that it attacked by preference the young and strong, but while statistics show that three-fifths of all cases occur from the first to the fourteenth year, the number of cases after forty-five is double that between fourteen and forty-four; and Jürgensen agrees with Flint in noting that it is the weak rather than the strong who are attacked by preference.

Jürgensen has also observed at Tübingen, at least, an interesting meteorological influence upon the occurrence of pneumonia, having noted that when the rainfall exceeded the mean, the cases were fewer, while an increase followed a fall below the mean—a relation to ground moisture similar to that so long observed in the case of typhoid fever. Edlefsen had observed the same relation at Kiel.

A further analogy to typhoid is observed in the effect of hygienic surroundings and peculiarities of its habitat upon the development of pneumonia, and Jürgensen called attention to the discovery by Emmerich, of the pneumonicoccus in the steerage of vessels. The question as to the contagiousness of pneumonia cannot, at present, be answered, it being very difficult to say of so widespread a disease, whether a case of apparent transmission is actually such, since it may depend upon certain coincident hygienic influences.

As to whether the poison of pneumonia is single or multiple, further information on this may be expected when the study of the microparasite is completed, but from a clinical study we dare only infer its unity, the striking variations in type and localization with which we are all familiar being in no way peculiar to it, but characteristic of all infectious diseases. The poison circulating in the blood has a special preference for the lungs and pleura, but it may manifest itself also in other situations, as is shown in cases in which the disease is ushered in by other symptoms, which give place at a later stage to those of pneumonia. Thus, Nauwerk found in the kidneys of thirteen cases dying of pneumonia, Friedländer's cocci, also incomplete zoöglea masses, in the veins; and Jürgensen discovered, in a case of pneumonia with cerebral symptoms, numerous cocci in the brain. Another peculiarity of the pneumonia poison is that its action is not gradual, as in typhus, but spasmodic, a special expression of this character being evinced in the temperature, which, in addition to the normal daily variations, exhibits numerous small variations throughout the day.

It is natural to expect that treatment should be modified to adapt it to such a view of pathogenesis. Hygiene, of course, acquires great importance, but, as yet, Jürgensen admits that treatment must, for the most part, be symptomatic. Iodine has been strongly recommended as an abortive measure, but he has had no experience with it. Especially is the heart to be watched, and an intermediate degree of antiphlogosis is recommended.

In the discussion which followed, Gerhardt ac-

cepted the views of Jürgensen as to the unity of pneumonia, and ascribed the so-called complications to a single poison operating diversely, as, for example, does the poison of scarlet fever. As to treatment, he, also, as well as Rühle, recommended the expectant and symptomatic method, with constant regard to the heart. In severe cases, he used quinine, and in high fever the cold bath, with simultaneous stimulation of the heart.

Fräntzel referred to the jaundice of pneumonia, a symptom imperfectly understood, which is sometimes accompanied by gastric symptoms, and at others not. He believed that the doubt regarding this symptom, especially in cases unaccompanied by gastric symptoms, was removed by the new views, since in these instances, at least, it might be regarded as hæmatogenous.

Rühle thought the infectious nature of pneumonia scarcely established because we dare not exclude altogether cold as an etiological factor. Rosenstein believed that pneumonia might be infectious, but not necessarily so; that it may be secondary to contracted kidney or to brain disease; and that treatment must vary according as the case is infectious or not. Jürgensen, however, thought these secondary pneumonias are not croupous.

Nothnagel cautioned against the too free use of alcohol, which he used only as a stimulant to the heart when it required it.

It is evident from the above that as yet little has been added to our knowledge of a proper treatment of croupous pneumonia, based upon the new views as to its pathology; while we are not certain that harm may not result from the unsettling of well-established principles of treatment. It is well known that, of late, the expectant plan of treatment of pneumonia has become quite general in some sections of this country. It is also well known that the mortality has increased during this period, rather than diminished. It is the belief, too, of men of large experience that some of the fatal cases would have terminated otherwise, if active antiphlogistic measures had been used; and we are ourselves inclined to believe that the expectant plan has been too generally followed, and that better results would have obtained if bloodletting were more common in this affection. It may be true, as Rosenstein suggested, that certain cases of pneumonia may be infectious, and others true inflammations, and that the treatment should differ accordingly. We do not, however, believe that the recognition of these differences of origin and nature is sufficiently easy to justify so complete an ignoring of antiphlogistic treatment. At any rate, the expectant and restorative plan is so invariably unsuccessful in grave cases that the antiphlogistic can scarcely be more so, and we recommend a more general return to it.

DR. GROSS'S PAPER UPON LACERATIONS OF THE FEMALE SEXUAL ORGANS.

Our readers will be glad to have presented them the very remarkable paper prepared by the late Dr. Gross, for the Obstetric Section of the American Medical Association, and, by his own arrangement, now published in full in The Medical News. The paper is of great interest as the last contribution of its distinguished author to medical literature; shortly after its completion, there came the weary weeks of physical prostration and pain, ending in death. There seems something almost sacred in this final work of one of the greatest men of the age, one to whom American medicine is most deeply indebted among her sons in the present century; it is not to be treated with irreverent pen, a jest would seem very profanity. It is a paper the full meaning of which cannot be had unless by careful reading and reflection.

We understand by it, in the first place, that the author had faith in the wisdom and goodness of nature, and then that it seemed to him these were being thwarted when so many women in the exercise of the reproductive function suffered such serious injuries as the gynecologist declares. Admitting the facts, they must result from bad obstetric management, from doing wrong things, and from failing to do right things.

But we think that the facts have been by some multiplied and exaggerated. For example, genito-urinary fistulæ are rare, and, so far as our observation teaches us, are of much more frequent occurrence in the practice of midwives than of physicians. These accidents may be apparently more frequent to-day than in the time of Dewees, simply because now they are cured, thanks to the patient genius of Marion Sims, and they become known; for in every State, nay, in almost every county of every State, there are surgeons capable of curing at least the great majority of cases, while formerly these unfortunate sufferers hid their infirmity by utter seclusion. So, too, in reference to the graver forms of perineal tears; for little more than a quarter of a century has passed since the late Prof. Meigs asserted them as incurable, and therefore sufferers would naturally shrink from revealing their unfortunate condition, since no good could come from the revelation.

Further, it is needless for us to repeat what has been so recently stated in our columns as to lacerations of the cervix in labor; they are, in the great majority of cases, simply physiological tears, not pathological in origin or in consequences, and, therefore, only exceptionally demanding or even excusing operative interference; that the parous os and cervix are to be brought back by a plastic operation to the condition of the virgin os and cervix, is a vagary which must finally cease.

But, taking the view which Dr. Gross adopted

from some leading gynecologists, there must be causes for these great evils, and means for preventing their occurrence. One cause for some of these undoubtedly, as stated by Dr. Gross, is the indiscreet, unnecessary use of the obstetric forceps. He has not uttered a single word in censure of this practice which will not meet the cordial endorsement of all thoughtful members of the profession; following his advice, many injuries, more especially to the perineum and to the external organs of generation, may be prevented.

But then, further, he advised bleeding in rigidity of the perineum, or of the os uteri; and if serious injuries to these structures are as frequent as represented—injuries that occur in spite of our morphia, chloral, and anæsthetic inhalations—by all means let us heed the words, and obey the teaching of our great master. The majority of the profession would agree in the advice, given by Dr. Gross, that bleeding is of value in threatened convulsions in pregnant women, though they might not regard the remedy as essential in all cases. While Dr. Gross stated other conditions in which he advised bleeding in pregnancy, in which few would be willing to follow the advice, unless very exceptionally, as, for example, in threatened miscarriage, yet the general lessons of his paper will be found more valuable the more they are studied.

GOVERNMENT REGULATION OF PROSTITUTION.

As from time to time the question of licensing houses of prostitution is discussed in this country, with the hope that by such action, with medical inspection of the inmates, the spread of venereal diseases may be checked, the latest facts in regard to the results of this plan are of interest. These are found in a volume published last year in Paris, upon "Prostitution in France," its author, Dr. Armand Després, having collected valuable statistics, and presented some important conclusions, the most valuable of which is that the more prostitution is subjected to regulations, the more prostitution is increased. Government control adds to rather than lessens the social evil.

Another conclusion is that where such regulation exists marriages are delayed, and the rate of increase of population falls most frequently to the minimum.

According to Dr. Després, there has been for years a steady depopulation of France, to be attributed indirectly to prostitution. The excess of births over deaths was only three per cent. in 1872, and in 1877 but one and three-fourths per cent. The facts and conclusions of Dr. Després are of very great importance and interest to the moralist as well as to the physician. Certainly they very clearly show that government regulation of prostitution is not an undoubted good.

Instead, therefore, of seeking to lessen venereal diseases by licensing houses of prostitution and subjecting their inmates to regular examinations, would it not be better, as suggested by our author, to make the communication of such malady a crime which, when knowingly committed, shall be punished by imprisonment of from six months to two years? Where the party communicating the disease was ignorant of the liability to do so, damages only would be required. But the court should at once compel these diseased persons, who were incapable of comprehending the danger they bore to others, to enter a hospital, where they should be required to stay until a medical examination showed that they were cured of all contagious accidents.

It is doubtful whether public sentiment in this country will ever permit legislation regulating prostitution in any way. Nevertheless there can be no question as to the urgent necessity of taking steps to prevent the spread of venereal diseases. Even if legalizing houses of prostitution were permitted, the disastrous results of such legislation, as ascertained in France, give no hope that it would effect the object in view, and therefore it would not be permanent. Possibly the plan of Dr. Després may be the best to lessen alike prostitution and venereal diseases. Certainly the question commends itself to the calm consideration of all thoughtful, conscientious, and philanthropic men, whether physicians or not.

PREGNANCY AND TYPHOID FEVER.

In a recent Paris thesis the reciprocal relations of pregnancy and typhoid fever are discussed. The author, Dr. Savidan, does not consider the prognosis in regard to the fever as materially affected by the pregnant condition, but in two-thirds of pregnant women abortion is caused by the fever, and he attributes the injurious result to the action of the typhoid poison upon the uterus, increasing its irritability, and upon the fœtus, killing it by the poison directly, or by hyperthermia. We doubt if professional experience in this country will confirm the alleged great liability to abortion caused by typhoid fever occurring in pregnancy. Personal observation leads us to put the percentum of abortion, or of premature labor, much lower.

In our issue of this and the preceding two weeks we have given in extra pages the equivalent of a whole number of The News, in order to promptly place before our readers full reports of the interesting annual meetings of the several national medical societies which have just been held.

SOCIETY PROCEEDINGS.

THE AMERICAN MEDICAL ASSOCIATION.

Thirty-fifth Annual Meeting, held at Washington, May 6, 7, 8, and 9, 1884.

(Specially reported for THE MEDICAL NEWS.)

SECTIONS.

SECTION ON OBSETRICS AND DISEASES OF WOMEN.

WEDNESDAY, MAY 7TH—SECOND DAY.

DR. THEOPHILUS PARVIN, of Pa., read a paper on

PUERPERAL SEPTICÆMIA,

in which he showed that the above title limited the disease to the condition in life peculiar to the female, and mentioned the physical, moral, and mechanical causes which are supposed to originate it. The causes are by some divided into autogenetic and heterogenetic; the former being a self-created poison endangering life. The autogenetic theory is a confession of ignorance. Scarlatina is never held to be autogenetic, although it may arise and be developed without apparent cause. By the theory of heterogenesis, woman enjoys greater safety. In sporadic cases of the disease the symptoms are the same as in those arising from assignable causes. Some well-known causes of the disease are found when it occurs after contact with the poisons of the cadaver, of epidemic erysipelas, or malignant uterine diseases, conveyed from the diseased to the susceptible patient, or from the miasms of the cesspool or the emanations of sewer gas.

Dr. Parvin related the occurrence of the disease in a patient in whom a retained placenta had been removed in fragments and incompletely. On the third day fever, sweats, and abdominal tenderness gave evidence of the affection, and the spread of the same disease to two neighboring patients showed its dangers. As in epidemics of scarlet fever the symptoms may be mild or severe, the intensity depending on the amount of the poison, the parts affected, the avenues of absorption, and the vital resistance of the subject. Its contagious powers have been demonstrated, and cannot be denied. Most obstetricians accept its cause as parasitic. To this effect we have the authority of Delore, Charpentier, Kleinmächter, as well as Spiegelberg, who shows it to be due to spherical bacteria. Milk fever is but a mild form of the affection, and the influence of microbes is also shown in phlegmasia alba dolens. Delore, 1869, Orth, 1872, and Heiberg, 1873, found the parasites with the exudations, and the last observer traced them into the lymphatics, and with them he produced the disease. Microbes, we know, act indirectly through a solution of septic products. During the first three months of the year's attendance at the Philadelphia Hospital in a total number of 72 women he had 20 cases of septicæmia and 3 deaths. This he accounts for in the bad hygienic conditions of the lying-in wards.

The author read some illustrative cases. One of a young colored woman, in which labor lasted twenty-four hours, the presentation being pelvic. On the fourteenth day after delivery, fever, pain, and symptoms of peritonitis announced the disease. *The patient did not have a chill;* death resulted on the seventh day. A *post-mortem* examination, made by Dr. Shakespeare, disclosed a general peritonitis, pleurisy, and pneumonia. The temperature at its maximum was but 103⅘° Fahr.

A second case was that of a patient who had had a good labor; she was seized on the third day with fever and delirium, *but no chill.* The uterus was tender, the temperature 105.3°, and death occurred on the fifth day of the disease. The autopsy made by Dr. Formad showed the lungs in an inflamed state and full of altered blood. The heart was soft, the muscles friable, and symptoms of a recent non-purulent peritonitis without exudation were present, whilst the mesenteric glands were much enlarged and full of cheesy infarctions. The size of the uterus was increased, its mucous membrane inflamed, and showing in parts commencing gangrene. The liver was that of acute yellow atrophy; the spleen was disintegrated, and the kidney softened.

Another case was that of a multiparous woman of twenty-four. It was a left shoulder presentation. The course of the labor was delayed by the accidental absence of the accoucheur. Podalic version was performed and a dead child delivered. By digital examination a vesico-vaginal slough was discovered on the second day. The patient had suppression of urine, irritable stomach, chills, fever, diarrhœa, and a foul lochial discharge. Death ensued on the eighth day. The examination after death, made by Dr. Shakespeare, disclosed peritoneal inflammation; uterus enlarged more than normally, its interior lining inflamed and partly gangrenous; and on the right side a rupture of the cervix and lower portion of the uterine body. The rupture was without indicative symptoms, an occurrence, as stated by Hervieux, as not infrequent.

Of seventeen cases which recovered, some had and some did not have chills. The secretion of milk was lessened or absent, whilst three constant symptoms prevailed: fever, painful abdomen, and arrested involution of the uterus. The highest rise of temperature noted was 106° F. The treatment was supportive, antiseptic, and antipyretic with uterine injections of carbolic acid solution or that of corrosive sublimate, 1 to 2000.

DR. SEYMOUR, of Troy, N. Y., mentioned an article in the April number of the *American Journal of Obstetrics*, in which he recorded the histories of two cases of the disease. In one it was associated with a traumatic hæmatoma of the right broad ligament, which suppurating, the patient died. The other was associated with a laceration of the supravaginal portion of the cervix on the right side. The uterus was washed out twice a day. In the beginning of the treatment a chill followed the injection, but this was subsequently avoided by the administration of twenty grains of quinine a short time previous to the introduction of the local antiseptic fluid. He thinks that his two cases will explain some of the conditions in cases in which examinations are not made.

DR. ROBERTSON, of South Carolina, has never seen a case of puerperal septicæmia in a negress during a practice of forty years.

DR. R. S. SUTTON, of Pittsburg, said that in obstetric practice he had served his day, and the sentiments expressed in the paper accorded with his own views. The disease is always perhaps due to a poison *sui generis*, and the autogenetic theory is but a confession of ignorance. Personal cleanliness is of prime importance,

and especially as regards the physician's hands. It is a precaution that all can take. The under surface of the tips of the finger-nails must be clean; the hands washed in turpentine and an alkaline solution.

Dr. Parvin, in reply to an inquiry, closed the discussion by saying that the antiseptics which he has used are two: carbolic acid and the corrosive sublimate. The experience of last winter led him to reject the use of vaginal injections, as the frequency of occurrence of the septicæmia was not thereby diminished, but in a certain number of cases it seemed to occur even more frequently. In septicæmia with fetid uterine discharge the intrauterine injections are indicated.

Dr. Wm. H. Taylor, of Ohio, read a paper on

THE MANAGEMENT OF PROTRACTED LABOR.

He limited his considerations to the conditions in the earlier stages of the process. He is justified in bringing up the subject by a quotation from Dr. I. E. Taylor on the neglect that the matter has received. The author thinks that rupture of the membrane should fix the close of the first stage. In the first stage the danger is exhaustion from pain, and the inhibition of labor by nerves of cerebral origin (*Lusk*).

Heretofore, active interference, he said, has been almost exclusively limited to the period after full dilatation of the os or even engagement of the head; but is not true conservatism to avert danger rather than be driven by some bad condition of the woman to a last resort? A commonly asserted cause of delay is "a rigid os." That such a state exists *per se* he doubts. Proper uterine contraction will be accompanied by appropriate changes of tissue of the cervix and os, and delay in labor attributed to a resisting os which is really due to insufficient uterine action, and local means resorted to, to dilate the os, are efficient from exciting uterine effort; spasmodic contraction of the os from fissure, too early rupture of the membranes, etc., may resist the powerful efforts of the uterus for a long time. While all are familiar with the symptoms of excess of liquor amnii, we rarely see notice of the effects of too little fluid; in such a case, Skene says: "A tense condition of the membranes may prevent bulging of the bag of waters, and the membranes may appear to the touch as if stretched across the os, or the head lies close down over the os uteri," and Dr. Taylor adds, a small uterine tumor, with the intestinal resonance, reaching close up to the solid mass. In protracted labor, if the head be not easily compressed, nothing will be gained by waiting, and he urged the adoption of version far earlier than is usually done. In the case under consideration, the head above the brim and the membranes unruptured, we have the conditions which make version easy and safe, and allow its performance before the woman is exhausted by long-continued suffering, and for the child we now have only the dangers of a breech delivery, which are less than an unaided delivery through a contracted pelvis. He rates it as the most valuable treatment.

Poverty and bad hygiene of cities are causes of the common pelvic malformations and of retarded labor. In the first stage ether, opium, Barnes's or Skene's dilator, and the forceps to bring the head into the cervix, may be required. Slight contraction of the brim is difficult to recognize. If the head be compressible, it may be permitted to wait. In early version with membranes unruptured the danger is less, and to the child only that of a breech delivery. He concurs with Johnson, of Dublin, in the early use of the forceps after rupture has prematurely occurred and pressure resulting. The view of Fritsch, that craniotomy should be done when pressure has long continued and there is no liquor amnii, because of the presumptive death of the child, will meet with little approbation in America.

Dr. Isaac E. Taylor, of New York, spoke of the gentle use of his forceps to bring the head in relation to the neck when digital dilatation, or dilatation by Barnes's method, is objected to. The use in such cases is a conservative principle.

Dr. A. Reeves Jackson, of Illinois, then read

A CONTRIBUTION TO THE RELATIONS OF OVULATION AND MENSTRUATION.

The aim of scientific investigations, he said, is the attainment of truth, and arguments to be successful must be based on known facts. After giving a short record of the dates and names of the early observers on the condition of the bodies first described by De Graaf, whose name they bear, the author continued to say that Baer, in 1827, by discovering that the follicle was not the ovule, but only the surrounding structure, laid the basis of the ovular theory of menstruation. Negrier, Barry, Fouchet, and others later on, showed that menstruation is due to ovulation. The theory became generally accepted because it seemed so reasonable, yet the author does not believe that all the facts have been fully observed or rightly explained. Ovulation and menstruation may be independent of each other. Malpighi saw the follicles developed in the fœtus and De Graaf the same in children. All obstetric writers admit that conception may occur without menstruation. A number of cases were quoted in which from eight to twelve children were born, the mothers not menstruating during the whole time. Yet arguments based on such facts are not satisfactory, since conception seems the preventive cause. Scanzoni admits that the Graafian follicles enlarge during pregnancy, and Meyhofer thinks this enlargement returns monthly during the period of gestation. Cases in which autopsies were made affirm these views. In a woman who had never menstruated, and who died at the age of seventy-eight, many false corpora lutea were found. Menstruation may occur without ovulation, as reported, in the cases of Gerhardt, Stedman, Senatri, and Meadows. Prof. Leypoldt has made a valuable contribution to the subject by his examination of the ovaries of thirty-two subjects in whom the date of the last menstruation had been fixed.

The author does not think that the point in dispute has yet been settled, but believes that Leypoldt shows that the Graafian follicles may rupture at any time without the occurrence of menstruation. He maintains, in conclusion, that there is no connection between the two but a mere coincidence.

Dr. H. F. Campbell, of Georgia, was pleased to find his views confirmed by the author. He, too, does not think that the two processes are to each other as cause and effect, but are independent. He thinks that after oöphorectomy menstruation is rather increased than diminished. He mentioned a case of Dr. Emmet, in which it continued for eighteen months afterwards, and

one of Dr. Engelmann of three years. The "egg-making" and the "nest-making" apparatus have also a distinct blood-supply. In another instance, after castration, the menstrual flow was so profuse that hæmostatics were needed. Puberty, with its signs, has a special purpose; it is to grow a womb and fecundated ovum. If favorable conditions do not exist, menstruation—a waste—ensues.

Dr. G. J. Engelmann, of St. Louis, thought that the above views tend too far in one direction. He has examined many menstruating uteri and finds the ovule to have burst within from the first to the third day of menstruation. He holds the two processes to be coexistent, but not dependent. The purpose of the uterine congestion is to thicken the mucous membrane and prepare a bed for the ovule. If impregnation does not follow, a flow of blood relieves the state of congestion and carries away with it the superabundant tissue.

As a rule, if one function be disturbed the other is also likely to be so. We are yet ignorant of the full facts. In a case in which he thought he had carefully removed the ovaries and all their tissues, conception followed in three years. In a similar case he thinks some ovarian tissue was left. In answer to a question, Dr. Engelmann said he has never heard of or seen a third ovary.

Dr. Healy, of Maryland, called attention to the fact known to sportsmen that the spaying a bitch after rutting has occurred fails of its purpose, and she is still followed by other dogs. He thinks it due to the establishment of a bodily habit, and points out the interest that would be attached to the case of castration in a subject who has never menstruated.

Dr. Robert Battey, of Georgia, thought that the discussion of the subject of menstruation is one in which opponents do not use the term in a common sense. Menstruation may occur in a child of four, a woman of twenty-five, and one of ninety-two. The one is true, the others pseudo-menstruation. Ovulation is not necessary to either, and in pseudo-menstruation the presence of Fallopian tubes, vagina, uterus, or vulva, is not essential for the occurrence. He holds that Dr. Campbell's views can be carried still further, and he asserts that sterility does not even follow after extirpation of the ovaries. He mentioned an instance of conception in which double ovariotomy had been done two years previously.

Dr. Jackson, in concluding the discussion, gave his definitions of ovulation as the ripening and extrusion of an ovule, and of menstruation, a sanguineous flow from the mucous membrane of the uterus. He does not think we can speak of a false menstruation because it occurs in a child or old woman. He has seen menstruation where only the cervix had been left after operation.

Dr. J. Herbert Claiborne, of Va., read a paper on

THE USE OF CHLOROFORM IN LABOR.

His conclusions are founded on two hundred cases in private practice. He thinks the anæsthetic is not used enough, and gives the following as his conclusions: 1. The process of labor in all its stages is facilitated by chloroform. 2. The duration of all its stages is shortened. 3. The pain of all the stages is entirely and safely blunted. 4. The occurrence of accidents is less frequent.

In opposition to his views he quoted the opinions of others as expressed in Playfair's text-book, in which it is to be used only during the second stage, and the dangers of post-partum hemorrhage is insisted upon. His own views were once identical with these, but he now wished to make a public recantation. He described the sufferings of the woman and the great blessing which she found in the anæsthetic. In exceptional cases, in which there is little or no pain, he does not think it necessary. In the first stage chloroform need only be given during the pains and not in quantities sufficient to produce unconsciousness. In a stubborn and undilated os chloroform relaxes the circular fibres and dilatation ensues. In the pains of descent and in the last severe agony the author's feelings impel to its use. He has not seen labor delayed or arrested. In only one instance was the perineum ruptured, and then as the result of the unskilful use of the forceps.

To show the influence of an anæsthetic on labor, he related the history of a woman who, upon some one's advice, became intoxicated just before her confinement, from the effects of half a pint of whiskey. In six hours every stage of labor was completed, yet during all this time there was no other manifestation of life from the mother. In the third stage he believes it increases uterine contraction and diminishes the risk of hemorrhage. Chloroform is the sheet-anchor in puerperal convulsions. As to its action in retained placenta and hour-glass contractions, he has had no experience. In instrumental and manual interference it is imperatively demanded. He used the chloroform prepared by Squibb—it is more rapid, certain, and agreeable than ether, whilst it does not possess its stimulating or intoxicating effects. In answer to an inquiry, the author replied that he has seen no bad effects on the fœtus from its use.

Dr. Jepson, of W. Va., has been more and more impressed by the frequency of short and easy labors; he has not observed the agony and suffering of which the author spoke. He found that chloroform induces hemorrhage by lessening the uterine contraction. He limits its use to instrumental deliveries or unusual suffering. In the majority of cases he lets nature do her perfect work.

Dr. A. Dunlap, of Ohio, made some remarks on

AN IMPROVED METHOD OF TREATING THE PEDICLE IN THE REMOVAL OF LARGE INTRAPERITONEAL FIBROID TUMORS.

In the removal of these tumors, a successful treatment of the pedicle is necessary to make the operation legitimate. He is satisfied that the pedicle after ovariotomy does not slough, but becomes revitalized. He has invented a clamp and self-threading needles, by which the pedicle is so secured that no hemorrhage occurs, and there is no laceration or injury to the peritoneum covering the stalk; the sutures and the divisions are both practised on the proximate side of the clamp.

THURSDAY, MAY 8TH—THIRD DAY.

Dr. Isaac E. Taylor, of New York, read a paper on

THE MANAGEMENT AND RECTIFICATION OF THE CHILD'S HEAD IN DIFFICULT CASES OF OCCIPITO-POSTERIOR PRESENTATION.

He gave a summary of the important views on the cranial position since the subject was treated by Naegele,

Sr., in 1819, the natural mechanism of the presentation, and the methods of treatment. He next considered the theories explaining rotation of the head. He holds that the movements of the child's head is explained by the action of the uterine forces on the vertex. The uterine action must coincide with the uterine axis. In some cases he has seen rotation occur in the intervals of contractions. He thinks face presentations are accompanied with no more dangers than are occipito-anterior. Should the perineum be much distended, and the head unable to escape from under the pubis, artificial aid is needed.

For rotation to occur in some difficult cases it is essential that the shoulder enter the superior strait, and rotation of the head and shoulder to coincide. In the use of the forceps he pointed out the necessity between consonance of action in their use, and natural rotation. Traction, too, may cause serious injury. When forceps fail, manual aid is needed. The hand is the natural and essential means. We may either move the position of the head or make it a face presentation. Conjoined manipulation is of great value. The literature of the subject, and his own experience justify him in proposing the applicability of converting some of these cases into face presentations.

A paper on the

CAUSES AND PREVENTION OF LACERATIONS OF THE FEMALE SEXUAL ORGANS,

by the late Dr. S. D. Gross, of Philadelphia, was read by Dr. S. C. Busey, of Washington, D. C. (see page 599).

Dr. Battey, of Georgia, said that he has never regretted the use of the lancet; he does regret that he has not used it more boldly.

Dr. Campbell, of Georgia, remarked that he was glad that his views were consonant with those of Dr. Gross and Dr. Battey. Bloodletting in labor and in eclampsia has been unjustly condemned and laid aside. As substitutes we have chloroform, chloral, potassium bromide, and cold to the head. If puerperal convulsions be due to anæmia of the brain, why give such exsanguinating remedies as these? If, however, uræmia be their cause, then the presence of urea is due to renal congestion. Then we should bleed to bring about healthy elimination from the kidneys. An experiment he performed on a common fowl, makes him question the statement that bleeding will produce convulsions. For having cut all the tissues through down to the cervical cord in front, the bird died without a struggle.

Dr. T. B. Harvey, of Indianapolis, with the utmost respect and honor for the great author, thought the subject should be freely discussed. He thinks the other side ought to have an expression of opinion. He began to bleed because of the teachings of Dewees, but he now obtains better results from chloroform and opium.

Dr. R. S. Kinloch, of South Carolina, was anticipated in some of his remarks by Dr. Harvey. Dr. Gross is an illustration of the power of early impressions. He disagreed entirely with the statements made in the paper. He has never bled in a practice of thirty-five years, and has lost but two cases dependent on the parturient state. Would Dr. Gross have applied the same rule to surgical cases? The effects claimed are *post hoc*, and not *propter hoc*.

Dr. Seymour, of Troy, N. Y., thinks the locality of importance in the good results from venesection. In Vienna it has been shown that bleeding is not necessary in the treatment of puerperal convulsions.

Dr. T. A. Reamy, of Ohio, said that, whilst mourning the death of the great man, his paper should stand on the same ground as if he were living. Hence, he could not let the article go on record unchallenged. In advocating "bleeding for fever," he does not make the distinction that the febrile state may be but the storm produced by sepsis. Why lessen the quantity of the blood when physiology and Scripture teach that it is "the life thereof." For a rigid os and nagging pain, the rationalist would give chloral or morphia; or, if the pulse be high, an arterial sedative. In only a few cases of puerperal convulsions is bleeding best. Especially will these be few after one has once seen the effects of morphia. No doubt the forceps are used too frequently by some, but the remarks of Dr. Gross cannot apply to the light and elegant forceps of modern times. The present student uses the instrument better after practice of two years than did the average practitioner of twenty years ago. Recent works have made the subject plain. The forceps is not used more than once in fifteen or twenty-five cases.

Dr. Wathen, of Kentucky, thought that chloral and chloroform deplete the brain less than bleeding does. He has never seen a case in which fever or abortion could be benefited by it. It is applicable in puerperal eclampsia, where excess of the blood in the brain may be fatal. All of the woman's blood is needed to sustain the puerperal condition properly. He thought the Society should not adopt so pernicious a doctrine until it had been well considered.

Dr. W. M. Findley, of Ohio, then read a paper on

THE RATE AND CAUSE OF MORTALITY IN ONE THOUSAND CASES OF LABOR IN PRIVATE PRACTICE.

The fatal result in some of the cases he accounted for by the wretched condition of the patients, and the time that elapsed before assistance could be given.

Dr. Wm. T. Lusk, of New York, read a paper on

SUDDEN DEATH IN LABOR AND CHILDBED.

He was called to patient on the first of January, 1884, at 6 A.M. She had been in the erect posture for hours. She did not wish the forceps to be used. At 1 P.M. her face was colorless, but there were no symptoms of suffering and an anæsthetic was given. A child was delivered by means of the forceps. As was anticipated, hemorrhage occurred, and was arrested by hot-water injections after a few pints of blood had been lost. The patient had all the appearances of severe shock, and died at 7.30 P.M. He considered the causes of sudden death resulting from pulmonary embolism and air in the veins, and illustrated his remarks by the histories of cases and the results of autopsies. He considered, therefore, death as resulting from nerve exhaustion or shock, and in which neither air-bubbles nor embolisms are found. Pathology teaches shock to be due to reflex paralysis, especially of the splanchnic nerves. The causes predisposing to severe shock are well known in military surgery, and it would be singular could not similar conditions prevail in childbed. In the process of labor the torture is as great as that which victims of justice once suffered, in whom, as is well known, *shock*

often put an end to the agony. He insisted, in conclusion, on the dangers of a prolonged first stage when the membranes are unruptured.

Dr. B. B. Browne, of Maryland, then read a paper on

MALFORMATIONS IN THE FEMALE SEXUAL ORGANS RESULTING FROM ARREST OF DEVELOPMENT.

Case I.—A small female, who never menstruated. The external genitals were well developed, the vagina ending in a cul-de-sac one and one-quarter inch long. Neither uterus nor ovaries could be detected.

Case II.—A. R. Had periodical headaches, and had never menstruated. External genitals normal, hymen intact when cut, and infantile cervix perceived. Electricity was used once a week; the patient menstruated, and the uterus developed.

Case III.—M. T., aged nineteen. Had never menstruated; she had monthly pains in the head, relieved by epistaxis. The uterus was small, the cervix nipple-shaped, and the os permitting the passage of a probe. Cured by electricity.

Case IV.—Autopsy of a female aged nineteen; had never menstruated; vulva natural, vagina ending in cul-de-sac three inches deep, no rugæ on surface. Bladder and rectum adherent; ovary, uterus, and Fallopian tube of the size of an apricot.

Case V.—A. T., aged thirty-two. Had never menstruated; was well developed. There was intense sexual desire. Vagina ending in cul-de-sac two inches deep. The finger met an elevation—the rudimentary uterus—on the right side.

The author's conclusions are: 1. Malformations before puberty are due to arrest of development. 2. The ovary is developed with the uterus. 3. The external genital organs are developed independently of the internal. 4. The patulous urethra found is due to an arrest of development, and not to sexual intercourse. 5. In congenital atresia a patulous vagina is the rule, not in the acquired.

The following papers were read by title: *On a New Suture*, by Dr. S. C. Dudley, of Illinois; *Mechanical Methods and Appliances in Uterine Dislocations and Distortions*, by Dr. H. F. Campbell, of Georgia; *Surgical Operations for Cancer of the Uterus*, by Dr. W. H. Byford, of Chicago.

Section on Surgery and Anatomy.

Wednesday, May 7th—Second Day.

The first order of procedure was the discussion on the paper of Dr. F. S. Dennis, of New York, on the

TREATMENT OF COMPOUND FRACTURES.

Dr. Quimby, of New Jersey, remarked that in all compound fractures it is highly important that all sharp fragments of bone be removed in order to prevent their irritating action on the wound. In speaking of Listerism, he called attention to the fact that even with the use of all the antiseptic measures of that system, bacteria have been seen to thrive.

Dr. T. R. Varick, of Jersey City, then read a paper on

RAILROAD INJURIES OF THE EXTREMITIES, WITH OBSERVATIONS ON THE SITE OF AMPUTATION, AND SUBSEQUENT TREATMENT OF THE STUMP.

He considered injuries to the extremities not only when the result of railroad accidents, but also when inflicted by any crushing blows at great momentum. He spoke first of the increasing frequency of these injuries, with the increasing use of heavy machinery. Owing to the great weight and high rate of speed, injuries inflicted by trains in transit are of a most destructive character. The traumatism is not confined to the immediate part struck. The appearance of the integument is not always a criterion of the condition of subjacent parts, as there may not be the slightest abrasion thereon, and yet the underlying muscle and vascular systems may be hopelessly destroyed. In reference to the *modus operandi* of a force acting in this manner, the author gave this explanation: We know that a muscle may be ruptured by its own contractile force, especially when taken by surprise, or in an awkward position when struck. The effect of blows in producing muscular contraction was illustrated by the patellar tendon-reflex. The same phenomenon follows a blow upon the tendo Achillis with the foot firmly flexed. Since Gowers has shown that this contraction followed the blow too quickly to admit of the stimulus travelling to the spinal cord and down again, the movement must be due directly to the stimulation of the muscles themselves. A blow upon a muscle held in extreme tension causes violent and repeated contraction, and in a case in which great momentum inflicts the blow, it is fair to assume that rupture of the contracting muscle or its tendon to a greater or less extent may ensue. In railroad injuries, the involuntary contraction in conjunction with the efforts of the victim to free himself, would produce some of the lesions which come under our observation. Again, the liquids of the body are confined within strong tegumentary and fascial coverings, blows rupture these envelopes in many places, pulpify and comminute the tissues beneath and eject the fluids to a distance, it may be, into other tissues; and the lymph and blood are thrown back through the large vessels with the momentum of the blow struck. This force, the author said, is received on the one hand by the right side of the heart, and may result in a fatal paralysis. He considers the rupture of vessels a fortunate occurrence, as relieving this tension. On the other hand, the blood flowing from the arterial side of the heart is also suddenly arrested.

In speaking of the site of amputation, the author said that he had made it a rule to give the point of injury a wide berth, since he had found that, no matter how skilful the operation, if it did not go beyond the contused part of the limb, sloughing of the stump occurred. This sloughing, too, involves not only the integument, but the connective and muscular tissues in some cases, the muscles sloughing even more than the integument. It matters little what method of operating is employed. The author, however, referred to a number of important points in the general care of the limb before and after the operation, including its dressing with proper antiseptic precautions. The importance of a large drainage-tube was insisted upon. Conservative surgery was recommended in all injuries of the hand and foot, amputation being avoided in most cases.

Several cases were reported illustrating the severity of injuries, the dangers and complications that may ensue, and the best methods of treatment. That the treatment was a successful one, the author supported by statistics, showing that of twenty-one major amputations made by him, all recovered, and of five other major

amputations he had but one death, and that, due to secondary hemorrhage, on the fourth day, in a debilitated patient. In conclusion, the author epitomized his treatment thus: Amputate through sound tissue, and keep the stump clean.

DR. QUIMBY thought it was a great mistake, and one too often made by physicians, to think that because a railroad injury caused no immediate severe symptoms, the time of danger was passed. Cases were referred to in support of the statement.

The committee appointed to draft

RESOLUTIONS ON THE DEATH OF DR. S. D. GROSS

reported the following:

Resolved, That the Surgical Section of the American Medical Association have received with a sense of profound regret the intelligence of the death of Samuel D. Gross, of the State of Pennsylvania, one of the greatest ornaments of this Association, and one of the most distinguished teachers and authors in the medical profession of the United States.

Resolved, That the memory of the deceased deserves to be cherished with love and veneration by the members of the profession. As a man thoroughly versed in the medical science, he is worthy to be ranked with the greatest and ablest of our age and country. He had mastered the vast learning of his profession, and the natural kindness of his great and generous heart was such that throughout his long and successful career as a practitioner he was continually experiencing the most intense satisfaction in relieving, by his science, the sufferings of humanity.

Resolved, That a copy of the resolutions be printed in connection with the record of the transactions of the Section, and that a copy should be transmitted to the friends of the deceased.

The paper of DR. CHARLES A. LEALE, of New York, *Tracheotomy in Diphtheria*, was read by title.

SPONTANEOUS FRACTURE OF VESICAL CALCULI.

DR. J. W. S. GOULEY, of New York, presented a specimen of a calculus which had undergone what is usually known as spontaneous fracture within the bladder. The question, he said, is whether spontaneous fracture ever occurs, and if so, how; if not, what the phenomenon truly was. The specimen presented consisted of eighteen or twenty fragments of various sizes and shapes, and the speaker did not doubt that a considerable number of similar pieces had escaped by the urethra. This detritus came from a patient seventy-nine years of age, who had been under treatment for some obscure vesical trouble for a year or more, and into whose bladder sundry instruments, soft and metallic, had been introduced. About two years after first noticing the trouble, he fell into the hands of a physician of this city, who dilated the urethra somewhat and discovered a stone. After the sound had been used for a week or two, the patient passed several fragments from the urethra. The patient had probably some, but not great, hypertrophy of the prostate, or the fragments could not have passed. On several occasions he passed other fragments, and the rest of the small fragments were removed by aspiration. Some time after this, the patient was submitted to an operation, after which he did not long survive. The speaker believed it a case of what is known as spontaneous fracture. The stones were all smooth, but did not present any regular facets. The fracture had evidently occurred some time, probably months, before the passage of the fragments.

In regard to the question, How does this phenomenon occur? the speaker said that he thought the best explanation he could give for it, since so little is said of it in the text-books, was that the fracture was similar in occurrence to that which occurs in Prince Rupert's pearls. He thought it probable that a vesical calculus might, like these little drops of glass, be very hard and smooth, and yet, if scratched to never so slight a degree, fly to pieces. He thought it not at all unlikely that the instruments introduced so frequently might have produced a slight erosion, causing the fracture.

DR. L. A. SAYRE inquired whether the speaker had had an opportunity to examine the patient before the time of operation, and whether he could state anything in regard to the size of the stone before fracture.

DR. GOULEY replied that the stone had been broken long before the operation occurred, and before he first saw him.

DR. J. FORD THOMPSON, of Washington, reported that he had performed a lithotomy in which he found a fractured stone. He had introduced sounds, and had attempted to crush the stone by Bigelow's method, but the bladder was so contracted that he found it impossible to separate the blades of the instrument far enough to get even the smallest fragment into it. He was positive, therefore, that he had not caused the fracture of the calculus with it. After operating, he extracted five stones, each much larger than any of those presented by Dr. Gouley. He believed, however, that he must have broken the stone in extracting it, for it was rather soft, and he did not consider it a spontaneous fracture, yet he thought it possible that the firm contraction of the bladder might have caused the fracture. The case terminated very much as did the case of Dr. Gouley.

DR. HUTCHISON, of Brooklyn, presented a mulberry calculus which he had removed a year ago from a young man of twenty. After recognizing the condition in the usual examination, he had performed the bilateral operation, and found the stone in two fragments, as he now presented it. The patient had never had any instrument in his bladder until he introduced it, and he had never suffered any pain. He was satisfied that this was a case of spontaneous fracture.

DR. PREWITT, of St. Louis, asked Dr. Hutchison whether the calculus presented by him showed a distinct line of fracture, or if the edges were smooth and rounded off. The reply was that the line was distinct. He then said that he thought it possible for a very much contracted bladder to cause the fracture of a soft calculus, but that certainly such could not occur in a mulberry stone.

DR. POLLOCK, of Pennsylvania, reported that he had operated upon a patient seventy years of age, and had removed from his bladder sixty-six stones. They were of regular triangular, pyramidal form. He said that the idea of spontaneous fracture had not occurred to him until now.

DR. W. W. DAWSON, of Ohio, thought that the calculus exhibited by Dr. Gouley must have been broken, if broken at all, by his instrument. It is impossible for

the bladder to contract on a stone so as to fracture it. One point in the history of Dr. Hutchison's case struck him forcibly, and that was the absence of pain. He had found this usually the case where the rough surface of the calculus had become worn smooth. He had once removed a remarkably large mulberry calculus, fully as large as a hen's egg. That patient had for fifteen years suffered from irritability of the bladder, having to rise at night more frequently than he should, but further than that there was nothing at all to indicate the presence of a stone. He had no pain.

DR. GOULEY agreed with Dr. Dawson in regard to the impossibility of the bladder ever causing fracture of a stone contained in it. He said that a bladder so contracted and contractured had not strength enough in its walls to expel the urine, and of course it could not break a stone. But, besides that, it was unscientific, unpathological, and unsurgical to think of such an occurrence. He preferred the explanation he had given, comparing it to Prince Rupert's pearls.

DR. PREWITT asked how, if this comparison were correct, it happened that in Dr. Hutchison's stone there was but a single line of fracture, and not numerous, since the glass drops usually break into many pieces.

DR. GOULEY thought it a remarkable exception to the rule.

DR. C. A. WHEATON, of Minnesota, contributed a paper on

AMPUTATION AT THE HIP-JOINT, WITH A REVIEW OF THE VARIOUS METHODS OF CONTROLLING HEMORRHAGE.

He said that as he had made two amputations at the hip-joint during the past year, according to the recent method of Mr. Lloyd, of England, this led him to review the literature of the subject from its first employment, in 1848, to the present, with special reference to the methods of controlling hemorrhage.

The various methods were then narrated; pressure with the thumb or fingers, securing the vessels as they were divided in the flaps; pressure upon the common iliac, or on the aorta; tourniquets of various kinds, and preliminary ligation. The speaker then discussed the objections to these methods on the ground of their inefficiency, the delay or the dangers of trouble following their employment. There was danger to the sound side as well as to the diseased from the pressure of a tourniquet. Davie's lever, which has been most in favor, has always been considered safe, but a death occurred from it not long ago, due to peritonitis occasioned by its use. The hand has been introduced into the rectum to control the circulation, but this is not free from danger, and the arm of the assistant is frequently in the way of the operator. Reference was also made to a case reported by Dr. Varick, in the *American Journal of the Medical Sciences*, October, 1882, in which Trendelenburg's method was used; this consists in transfixing the leg with a small spear-pointed rod, running through close to the bone and making pressure by a figure-of-eight cord passed around the limb and over the ends of the rod, then amputating with the Lisfranc knife. He also described the method of Mr. Furneaux Jordan for articulating, and several other methods, including a detailed account of that by Mr. Lloyd.

DR. T. R. VARICK, of New Jersey, in moving the reference of the paper for publication, stated that he had recently made the Lloyd amputation. He also exhibited the spear used in the method by transfixion referred to in the paper, and stated that with it he had been able to make an almost bloodless operation.

DR. BYRD, of Illinois, remarked that he saw no need for an assistant to hold the rubber cord in place in the operation of Lloyd. He had modified it by passing the cord up over the anterior superior spinous process of the ileum, then down and around the limb, forming an eight; the ends were then tied, and no assistant was required.

DR. MURDOCK, of Pennsylvania, expressed distrust in the elastic compression where the limb is well developed and very muscular.

DR. DAWSON reported the case of a child upon whom he made this amputation about two years ago, using only the elastic tourniquet. He was surprised at the ease with which the hemorrhage was controlled, the operation being literally a bloodless one.

DR. MCGRAW stated that he had amputated three times at the hip-joint, with but one death, and that he controlled the hemorrhage with very little difficulty, and with no important loss of blood.

DR. MACLEAN favored the use of the abdominal tourniquet. He said it was very simple, easily applied, safe, and secure. He had never had any bad effects from it, except once where he applied it too long before it was required. He used the abdominal tourniquet in operations well down in the thigh.

The papers of Dr. Joseph Ransohoff, of Cincinnati, on *The Excision of Nasal and Naso-pharyngeal Polypi by a New and Easy Method;* of Mr. A. Pearce Gould, F.R.C.S., of London, on *Twelve Months' Experience at the London Temperance Hospital;* of Dr. Roswell Park, of New York, on *Tuberculosis of Bones and Joints, and Its Treatment by Ignipuncture;* and of Dr. C. B. Nancrede, of Philadelphia, entitled *Is Carcinoma Mammæ Curable by Operative Procedure,* were read by title.

DR. WILLIAM A. BYRD, of Ill., then read a paper on

A CALCAREOUS CALCULUS FOUND IN THE SUBSTANCE OF THE LIVER,

in which he reported a case that he considered unique. The patient had been suffering for four months with fever, rigors, and colliquative sweats, and had been treated by various physicians for malarial trouble. When he examined him, he found enlargement of the liver, and making an incision between the ninth and tenth ribs gave vent to a pint of pus. Probing the wound some days after, he discovered a hard body that he at first mistook for necrosed bone; being unable to remove it with the forceps between the ribs, he excised an inch and a half of the tenth rib, and removed it. During removal it broke, but the fragments aggregated a larger mass than the end of a man's thumb, and when dry weighed one hundred and fifteen grains. In appearance it was phosphate of lime. He considered it likely to have resulted from a thrombus of some branch of the hepatic artery cutting off nutrition from a portion of the liver which became the seat of the earthy deposit. The patient from whom it was taken recovered.

DR. N. SENN, of Milwaukee, then read a paper on

BRANCHIAL CYSTS OF THE NECK.

He referred first to the importance of all tumors of

the neck, because of their location. He then reviewed the numerous names applied by different authors to what he preferred to call branchial cysts. He choose this name because it expressed more correctly the nature of the affection. The anatomy of the structures involved was then closely studied, including the embryonal development. The location of these tumors was then found to correspond to that of the branchial clefts of the embryo. They are more likely to occur in the second and third clefts than in others, although they may occur in any part of the neck, the immediate cause being the folding in of a portion of the cleft so as to form a closed sac.

The literature of the disease was closely studied, and a large number of cases referred to as reported by Langenbeck, Billroth, Virchow, and others, with references to the opinions of the operators in regard to them. The histological structure of the cysts was next described, and the ciliated epithelium sometimes found in them traced to the origin of the tumor in the branchial cleft. The character of the contents of the cysts depends largely upon the amount of retrograde metamorphosis that had occurred in it. The varieties of branchial cysts were named mucous, atheromatous, serous, and hæmatoid. Unlike cutaneous cysts, these tumors never contain the products of the secretions of the skin, but only the products of a retrograde metamorphosis of the epithelial cells lining their interior. The different varieties were described, and a number of cases reported, including three which had occurred to the author.

In regard to the time of the development of these tumors, the essayist said that, although they owe their origin to an embryonal tissue, it is not essential that they should begin their growth at so early a period. It is only necessary that the tissue be there formed, and the abnormal growth will occur later in life. The most frequent time for this to occur is at puberty.

Although it is not essential to a proper treatment of the tumor that a positive differential diagnosis should be made between it and cutaneous growths or cysts of other kind, the use of exploratory punctures was advised. The various other methods of differential diagnosis were also carefully considered. The methods of treatment that have been tried are, incision, the actual cautery, seton, and puncture, with the subsequent injection of irritating fluids. The treatment must be thorough. Nothing short of complete extirpation is worthy of trial. Antiseptic measures should be in some cases, at least, added to the other treatment, and the general condition of the patient must be looked to.

Dr. W. A. Byrd called attention to the treatment by electrolysis, and expressed surprise that it had not been referred to by the author of the paper. He had tried it in several of these cysts, and found that it worked admirably. It is not painful, leaves no scar, and is perfect in its results. The great difficulty was that most persons do not use enough cells. He would not think of a less number than eighteen, and would not hesitate to use a stronger current.

Dr. Senn replied that he had used electrolysis, but that it had failed. He could not see how it would be possible for such a treatment to remove a cyst lined with a tissue so much like skin, and so ready to proliferate. He would gladly accept any treatment that would remove these tumors short of a complete extirpation; but he believed that the only treatment was to resort early to a radical operation. The tumors, if they have not been meddled with, can usually be easily enucleated.

The paper of Dr. P. S. Conner, of Cincinnati, on *Intestinal Paralysis Consequent upon Acute Pressure*, was read by title.

Thursday, May 8th—Third Day.

Dr. Chas. W. Dulles, of Pa., read a paper on

the treatment of hydrophobia, historically and practically considered,

in which he gave an extended review of the literature of the subject from the days of Aristotle to the present time.

Dr. H. O. Walker, of Detroit, moved that, as the paper of the Chairman, Dr. Parkes, had been referred to the Section, and an opportunity for hearing it had not been given in the general session, the author be requested to read his paper before the Section.

Dr. Chas. T. Parkes, of Chicago, then gave a brief abstract of his address on

gunshot wounds of the intestine, and their treatment.

[See The Medical News, May 17th, page 563.]

Dr. Quimby asked how near together the sutures should be placed in the intestine.

Dr. Tremaine, U. S. N., stated that he had made a number of experiments with a view of determining the very questions contained in Dr. Parkes's paper. He agreed with that gentleman in the belief that the abdominal cavity should be opened in cases of wound of the abdomen, in order to see what damage had been done. He thought it a disgrace for a surgeon to stand idly by and do nothing in such cases.

Dr. Dunlap, of Ohio, had not had any experience in gunshot wounds of the intestine, but reported a case in which a large portion of the stomach was torn away by a shaft in a machine-shop, and yet the wound healed. He objected to the statement in the paper that parts included in a ligature of the mesentery sloughed; basing his belief that it became vitalized on what he had seen take place in the stump of an ovarian tumor.

Dr. J. Ford Thompson, of Washington, had the opportunity within the last year or two, to witness a great deal of abdominal surgery in the clinic of Billroth and other German surgeons. He had there seen a modification of Lembert's stitch, which was devised by one of Billroth's assistants, and which he considered better than that of Dr. Parkes. It consisted in first stitching together the peritoneal surfaces of one-half the calibre of the wound, then the mucous membrane on that and on the other half, and finally the peritoneal surface of the latter side; in this way leaving two rows of sutures which effectually prevented the passage of fecal matter or even of gases through the wound. It also did away with the danger of strictures, which are so common after Lembert's suture has been used.

Dr. P. S. Conner remarked that certain points must be remembered in the consideration of this subject. These experiments on animals, to determine with what result a bullet passes through the abdomen, and to ascertain the best method of treating the injury in man,

were all very proper, but the conditions in the one case are often very different from those in the other. There is also a great difference between the treatment of such cases in civil and in military practice. In the latter, cases are received earlier and the surgeon is at liberty to use his judgment; but in civil practice the cases are frequently not seen until hours have elapsed, and even then the patient often refuses to have anything done. He stated that during the late unpleasantness at Cincinnati, he had received a case in which he desired to open the abdomen, but was not permitted to do so until the patient was moribund. He referred to the value of the temperature as an indicator whether or not the intestine had been injured, and was pleased to hear what had been said in regard to letting the wound alone, as a fresh incision was much safer, as well as more convenient.

DR. BYRD reported a case in which he removed successfully several inches of intestine in a case of strangulated hernia occurring in a very old patient, who was moribund at the time of operation. He further stated that he had operated nine times on the intestine; three times removing a portion of the entire calibre; three times removing a section; and three times making an incision. In removing a portion of the entire calibre, he had cut vertically, in order to prevent the formation of a circular cicatrix, which might lead to stricture.

DR. MURPHY said that in his experience with gunshot wounds of the intestine, the patients all died. He moved a vote of thanks to Dr. Parkes for his admirable paper.

DR. SAUNDERS, of Tennessee, in seconding the motion, remarked that heretofore our patients have died without aid, but that hereafter no military surgeon would be justified in allowing an individual with a wounded intestine to die without an operation.

DR. PARKES, in concluding the discussion, said that he had studied the double suture carefully, and that there were too many objections to it. The chief objection urged was that it required so much time for its introduction that the patient would be dead before it was accomplished. He believed, too, that the danger of rolling in of the mucous membrane was just as great with the double as with the single suture. Further, his suture was not Lembert's, but was an entirely different and a better one, for it took a much deeper hold in the tissues.

DR. T. F. PREWITT, of St. Louis, read the report of

A CASE OF CHRONIC SEROUS SYNOVITIS OF THE KNEE, WITH AN ENORMOUS COMMUNICATING POPLITEAL BURSA EXTENDING TO THE TENDO ACHILLIS.

. The case reported was that of a young man who was accustomed to sit constantly in a damp room, upon a revolving stool, where he frequently struck his knee against his desk. In November, 1882, he came to him with a swelling of the knee. He had no pain, and he could not fix the date when the enlargement began. It subsided somewhat under treatment, but he again came to him about a year ago. This time not only was the joint enlarged, but there was a large fluid tumor extending down from the joint to the ankle. He hesitated in forming his diagnosis, and for diagnostic purposes, as well as to prevent the rupture of the sac, he drew off four or five ounces of a thick, albuminous fluid. The question of amputation suggested itself, but he could not then recommend it. Three days later, he drew off more than half a gallon of the same fluid from the bursal cavity, and aspirated also the cavity of the joint. He then washed out the cavities, and in order to determine whether or not a communication existed between the two cavities he injected a weak solution of carmine into the upper opening, with the result that he found it in the lower sac a few minutes after. Two weeks later the knee refilled, but the sac did not. He then withdrew the fluid, washed out the cavity, and applied a plaster dressing, and the trouble did not recur for some time. After about six months, he returned for treatment, with the fluid again in the joint. In addition to this, there was an abnormal mobility of the joint, and the limb was smaller than the other, and after the fluid had been again removed there was some roughness of the joint. He believed the case one not simply of an enlargement and distention of the joint and bursa, but one in which there was a hernial protrusion of the bursa of the gastrocnemius muscle, The walls of the capsule had been softened and weakened by pressure until they yielded. Allusion was then made to the six bursæ found in relation with the knee-joint, and their positions described. Reference was made to the literature of the subject, and a short description given of several important cases. The difficulty of making a correct diagnosis was also referred to. As for treatment, aspiration, the tincture of iodine, the splint, and perfect rest of the joint, were all that could be used, except such measures as the general condition of the patient would require.

DR. BENJAMIN LEE, of Philadelphia, did not believe the mere finding of colored fluid in the lower sac after it had been injected into the upper, sufficient evidence of a communication between the two. It might have passed by osmosis.

DR. PREWITT replied that the colored fluid was found too quickly to admit of that explanation.

The papers of Dr. Edmund Andrews, of Illinois, on *[illegible] Slow, Imperceptible Motion;* of Dr. J. C. Hutchison, of Brooklyn, on *Transfusion;* of Dr. Schuppert, of Louisiana, *Urethrotomia Lithotriptica;* and of Dr. Quimby, of New Jersey, entitled, *Alcohol a Narcotic Irritant, and therefore not a True Stimulant*, were read by title, and referred.

DR. E. H. BRADFORD, of Massachusetts, presented

AN INSTRUMENT FOR THE TREATMENT OF OBSTINATE CASES OF CLUB-FOOT,

by which, after division of the tendon, and, in some cases, of the plantar fascia, the foot was brought straight and retained in that position. The instrument consisted of a flat plate on which the foot rested, and to which three or four braces were attached by binding-screws, supporting-rods, by turning which, pads were brought against different parts of the deformed foot, and with proper adjustment the deformity relieved. The inventor stated that the foot could be brought into proper position in a few minutes by gradual tightening of the screws, without inflicting much pain.

DR. PREWITT reported the cure of a case of club-foot in a young lady of twenty, by division of the tendo Achillis and plantar fascia, with subsequent manipulation. He said that on account of the unquestionable deformity of the bones which occurred in these cases, he

could not believe it possible to rectify a case of long standing at one sitting.

DR. BRADFORD replied that he had once performed a tarsotomy as recommended by German surgeons, and that he was then convinced that the deformity was not so much in the bones as in the ligaments and the fibrous tissue about the joints.

DR. QUIMBY did not agree with the last speaker, because he had *seen* the bones deformed.

DR. GILL believed the greater part of the deformity was not in the bones.

DR. B. LEE, of Philadelphia, believed that the lecturer had introduced the correct plan of treatment. He had used a method somewhat similar in effect to this one with good results. He believed the instrument a good one, but would be afraid of the inflammation that might result from too hasty restoration of the deformity.

DR. HENRY O. MARCY, of Boston, read a paper upon

THE RELATION OF BACTERIA TO SURGICAL LESIONS,

in which he gave a careful review of the evidences upon which the belief of the deleterious effects of germs upon wounds, and through them upon the general organism, was founded. The discussion of what constitutes a poison to wounds was entered upon, and the various exposures to which open wounds were liable.

The most important indication in wound treatment is to secure an aseptic condition, which may be defined as a wound surgically clean. Experimental proof is constantly accumulating to show that the inflammatory and other changes which ensue in wounds, are with few exceptions the result of the vital activity of new organisms. There is abundant evidence to show at least the extreme probability that septicæmia and pyæmia are one and the same disease, and that their sole and invariable cause is due to micrococcus poisoning.

DR. G. L. PORTER, of Connecticut, read a paper on

AN UNRECOGNIZED DANGER IN SURGICAL PRACTICE — ENTRANCE OF AIR AS A SECONDARY COMPLICATION.

The sad experience of surgeons, and the experiments of investigators, have made familiar the usual symptoms of the dangerous, and often fatal, accident of the introduction of atmospheric air into the venous circulation.

The report made by Beauchesne, in 1818, of the death, within a half hour, resulting from the entrance of air through the rupture of the internal jugular, was followed by many others, until they now number nearly a hundred. At first, the danger-zone was thought to be limited to the venous pulse in the regions of the neck, but the rapidly accumulating reports of deaths elsewhere from the entrance of air has extended the field of danger. The majority of modern instances are from the entrance of air into the uterine sinuses, either after local injections, deliveries, or attempted criminal abortions. A short time since, after sudden death in suspicious circumstances, I found a punctured wound of the internal os opening into the uterus, separation of four inches of the decidua vera and the uterine walls crepitant and distended with air. Death within ten minutes.

Hitherto this danger has been considered only as an immediate complication of a surgical operation. The following case illustrates the unclassified danger that may be developed many days after an injury in a vein of small size, and comparatively remote from the heart:

Above the right temple, one inch above eyebrow, one inch from median line, a contused wound nearly two inches long extending upwards and outwards, penetrated to the bone and denuded the periosteum. Considerable hemorrhage for two days, finally stopped by domestic applications. On the fifth day, first seen by the doctor, who found the patient in a squalid room, suffering from well-marked trismus, equally severe on both sides; wound unhealthy, inflamed, and gaping. Appropriate treatment relieved the symptoms, and reduced the local inflammation. Upon the ninth day, trismic spasms returned; at 3 o'clock A. M., tenth day, there was a severe clonic convulsion, and shortly afterwards she was found gasping for breath, and coughing up a thick tenacious mucus. Nitrite of amyl gave speedy relief. Three hours later, she had a second convulsion, in which she died. Examination twenty-six hours after death: Wound open, pus at bottom of external angle. No decomposition of body. Abdominal organs healthy and normal. While sawing calvaria, frothy blood bubbled through a small opening. Bubbles of air in small vessels of brain—a spumous fluid in sinuses. The right cavities of heart, and the descending and ascending cavæ filled with the same mixture of air and blood—a spumous fluid, the left side of heart containing fluid blood unmixed with bubbles of air. Congestion of posterior portion of lungs; anterior normal.

Death was caused by air in the venous circulation, entering through divided or injured branches of the frontal or temporal veins, stretched and held open by the trismus. The first convulsion occurred when the air—gradually entering through a small opening—had over-burdened the heart and lungs; the comparatively small amount of air had formed with a portion of the blood a spumous fluid, which had been churned back into the veins, allowing the rest of the blood remaining fluid to pass on into the general circulation, and sustain life, until the air, constantly increasing in amount, had vitiated so much blood as to cause the second convulsion, and destroy life.

The following objections were raised and answered. Death could not have resulted from air in the veins because: 1. Injury was outside of the danger-zone. 2. Long time after original injury. 3. Small size of vein. 4. Absence of noise of entering air. 5. Questionable liability of the spontaneous generation of air in the circulation. 6. The instance is without a reported counterpart. The knowledge of the possibility of such an entrance of air suggests to every surgeon the preventive means of carefully closing and protecting the wound, and the remedial measures to combat the danger should its characteristic symptoms occur.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Sixth Annual Congress, held in New York, May 12, 13, and 14, 1884.

[Specially reported for THE MEDICAL NEWS.

WEDNESDAY, MAY 14TH. FINAL SESSION.

BY a common agreement, the morning and afternoon sessions were joined into one.

A paper on *Herpes Laryngis*, by DR. S. H. CHAPMAN, of New Haven, was read by title.

Dr. T. A. DeBlois, of Boston, then reported some

CASES OF BUCCAL TUBERCULOSIS.

This affection, he said, was sufficiently rare to deserve mention whenever it was met with, either where the tubercular deposit first showed itself in the mouth or where, after manifesting its presence in other parts of the body, it finally extended itself into that region. He did not believe there was any good reason to doubt that tubercles always existed in the lungs before they appeared either in the pharynx or the larynx, and he was fully prepared to admit the same in regard to tuberculosis of the mouth. He had met with two cases of the latter affection, and both of them speedily proved fatal. Having related these cases in detail, with the results of the autopsies, he again called attention to the very bad prognosis, and then gave a *résumé* of the literature of the subject.

A paper on *Goitre*, by Dr. William Porter, of St. Louis, was read by title.

Dr. C. E. Sajous, of Philadelphia, then read a paper on

HAY FEVER AND ITS SUCCESSFUL TREATMENT.

His conclusions were as follows:

First. There is an idiosyncrasy existing in certain individuals to become influenced by certain emanations or irritating substances.

Second. The idiosyncrasy is accompanied by a chronic hyperæsthesia of that part of the nasal mucous membrane covering the inferior and middle turbinated bones, the middle meatus, the floor of the nose and that part of the septum between the limits of the olfactory membrane.

Third. Organic alteration of these parts annuls that hyperæsthesia; preventing at the same time what symptoms the patient may be liable to in case of an access.

Fourth. Any destructive agent will induce that organic alteration, but the galvano-cautery is by far the best; being painless, effective, and devoid of all danger when used in practised hands.

Fifth. In order to obtain a satisfactory result, a sufficient number of applications must be made, covering the entire extent of the hypersensitive surface; without which the result will be doubtful.

Until after he had completed this paper, Dr. Sajous said, he had been entirely unacquainted with the labors of Dr. Roe in the same direction, as set forth in the papers which he had read before the Medical Society of the State of New York in 1883 and 1884; in which he claimed that the essential subjective cause of hay fever was found in the nasal passages, having been induced by disease, either latent or active; that the objective cause of the irritation of this tissue was mainly pollen; that a cure could be effected by the destruction of the nerve-filaments and enlarged vessels of the part; and that the latter could most satisfactorily be accomplished by the galvano-cautery. If he could not be the first, therefore, Dr. Sajous continued, he was glad to be a good second in this matter, and he felt gratified that his conclusions had been confirmed by the more extensive experience of Dr. Roe, who had commenced his present plan of treatment as long ago as 1879, and therefore anticipated him by two years.

Dr. E. L. Shurley said that he had employed the galvano-cautery with success in one neuralgic case and in two cases of hay fever; but instead of singeing the whole surface, he had limited the applications to special points where nerve-filaments originated.

Dr. Bosworth said that he hoped that in the discussion the matter of permanent effect would be given consideration. He should like to know how long the results achieved had continued.

Dr. Shurley said that in the only case of his upon which any conclusions could be based the patient had remained entirely free from trouble for eighteen months.

Dr. J. O. Roe said that he was very glad, indeed, to have the results of his investigations so fully confirmed by the entirely independent ones of Dr. Sajous. As far as the permanency of the case was concerned, patients upon whom he had operated as long ago as 1879 had remained entirely free from all signs of hay fever up to the present time, and the only case among all that he had treated in which there had been any return at all of the trouble (and this was in a greatly modified form) was one in which he found that there was a small portion of hypersensitive tissue still remaining which he had inadvertently overlooked at the time that he made the galvano-cautery applications. This partial failure, therefore, was due not to any inadequacy of the method of treatment, but simply to his own want of care in practising it; and it only went to confirm his established conviction that the completeness and permanency of the cure depended on the thoroughness with which the treatment was carried out. In regard to the diagnosis, there was a simple procedure which he thought was of the greatest possible utility. This was touching the mucous membrane of the parts alluded to with the point of a probe, when an attack of asthma or other symptoms characteristic of an acute onset of the hay fever trouble would instantly be brought on. It was thus in the power of the operator to test whether his treatment had been thorough or not; for if, after he had applied the galvano-cautery to all the parts which seemed to be implicated, he touched the mucous membrane in different positions and found that no reflex irritation was set up, he could rest assured that the cure would be complete. On the other hand, if such irritation was set up, it would be necessary to apply the cautery to such portions of tissue as showed the presence of this hyperæsthesia. Some cases were undoubtedly due (though this was certainly not true of all, as claimed by Dr. Harrison Allen) to obstruction of the nose and hypertrophy. In these it was necessary to destroy the hypertrophied tissue, and to be particularly careful to remove any projecting spiculæ of bone (if such there were) which might prove a source of irritation. All the passages should be rendered entirely free, so that if a slight amount of swelling of the mucous membrane should occur, as from cold, it need give rise to no trouble. In many cases, however, in individuals who did not suffer from hay fever, there was found much more extensive obstruction and hypertrophy than in those who were the subjects of it. This went to show, therefore, as Dr. Sajous claimed, that there must be a certain idiosyncrasy in the individual before he would be liable to the affection.

Dr. J. N. Mackenzie, of Baltimore, remarked that what the essential anatomical condition in hay fever was he would not pretend to say, but he felt sure that there

was, at all events, an abnormal excitability of the reflex nerve-centres. In one case which he had seen, the most terrible paroxysms occurred in connection with the menstrual periods, which it was wholly impossible to prevent or modify, while paroxysms coming on at other times the patient was able to control by stopping up the nostrils. As to the excitation of the paroxysms by *ab extra* causes, he did not, for a moment, believe that pollen, for instance, was the essential cause of the trouble, as a rule, although in some instances it might perhaps be. Many patients suffered from attacks of hay fever at times of the year when they could not possibly have been excited by pollen. In order that this affection should occur, he believed that there must be, first, a predisposition, either inherited or acquired; and, second (for the production of the paroxysm), an engorgement of the nasal mucous membrane, particularly that covering the inferior turbinated bone and the septum. To the theory of nasal obstruction, advanced by Harrison Allen, he could not subscribe. As regards treatment, he coincided with Drs. Roe and Sajous, that the best plan was to destroy the membrane of the area mentioned, no matter what the nerve-centres concerned in the trouble might be. By this means a part of the mechanism by which the disease was produced was abolished, and this was all that was necessary to put a stop to it. In concluding, he said that he would like again to lay special stress on the importance of the excitability of the nervous centres as a factor in the causation of hay fever.

Dr. Beverly Robinson, of New York, said that he had applied pure carbolic acid to the parts of the nasal mucous membrane referred to, with a very considerable degree of success. To the adoption of this method he had been led almost by accident, as on one occasion a lady suffering from a violent attack of hay asthma, to which she had been subject for many years, had suddenly applied to him in the emergency, and, happening to have the carbolic acid at hand at the moment, it occurred to him that it might perhaps be of service to try its effect. The result in this case had been so successful that he had been induced to treat others in the same way, and it had seemed to answer quite well.

Dr. Roe said that he could not agree with Dr. Mackenzie in regard to the part played by pollen in the causation of hay fever, as he thought it was a most important one. If the affection were not in some measure due to pollen, we should have it occurring at any time, while in fact the recurrences of the trouble were as regular as clockwork, and many patients could predict the precise day on which the attack would commence. This, he had not the slightest doubt, was because the ripening of plants occurred with such regularity every year, the paroxysms of hay fever being always coincident. The pollen theory seemed, therefore, to be a well-established one.

Dr. Mackenzie said that he thought, on the other hand, the attacks were just as bad in winter as at other times of the year, and hence could not be attributed to the irritation of pollen. They seemed to him to be associated to a great extent with meteorological conditions; and there were many sources of irritation besides pollen that would give rise to an attack, such as dust and exposure to cold in various ways. In regard to recurrence of the affection at a given day and hour each year, he believed that it was due in many instances purely to the imagination.

Dr. Roe said, in reply to Dr. Mackenzie, that it was a mistake to suppose that patients were not liable to the irritable effect of pollen in winter, as the latter might be in the air in some places at any period of the year, thus, he had known persons to be attacked with hay fever in the middle of winter after going into barns where hay was stored.

Dr. S. Johnston, of Baltimore, said that he himself was a subject of this affection, and that in his case the attacks always came on regularly on the 28th of August. By remaining in town and avoiding dust, however, he could get along comparatively comfortable while they lasted. He always suffered intensely, however, from railroad travel during the attack. Last summer he went away in the midst of it, feeling in pretty good condition when he left home; but when he reached Washington he suffered from a terrific paroxysm. From there he went up into the Alleghany Mountains, and as soon as he reached them all trouble instantly vanished. As long as he remained there he was perfectly free from it; but as soon as he got back to Washington he was again attacked. In his own case he had derived most relief from chloroform, eucalyptol, and the insufflation of one-sixth of a grain of morphia in solution. He thought the affection was undoubtedly due to an exciting element, combined with some neurosis.

The President expressed the opinion that in every case of hay fever there were three essential elements, viz.: (1) A neurotic. (2) A structural (in the nasal cavities). (3) A sensitive (sensitiveness to pollen, dust, or other source of irritation). If any one of these factors were removed, the case would be cured; and it was perfectly immaterial which element was eliminated. Thus, he knew of one case which was completely cured by the patient's overcoming an inherited neurotic tendency by means of a systematic course of hygienic measures undertaken for this special purpose. The combination of all the three elements was essential for the existence of the affection.

Dr. Sajous closed the discussion. He said that in advocating the theory of special idiosyncrasy he did not wish, by any means, to ignore that of reflex centres. Practically they were one and the same thing. The exposed surface in every case was the nasal mucous membrane, but if there were no hyperæsthesia here, there might be in other parts of the body, as the vagina, for instance. The hyperæsthetic condition of the nose was particularly sensitive to pollen, and, therefore, the latter was one of the most common exciting causes, and dust was very apt to act in the same way in the case of those who were not affected by pollen. The point made by Dr. Roe in regard to diagnosis and the assurance of a cure by the probe-test, he thought a very admirable one, and he would certainly always avail himself of its advantages in the future.

Dr. E. L. Shurley, of Detroit, read a paper on

THE COMPARATIVE VALUE OF THE GALVANO-CAUTERY IN DISEASES OF THE NASAL AND PHARYNGEAL CAVITIES,

the aim of which, he said, was to consider (1) the conditions necessitating the use of this or some other similar agent; (2) the comparative value of this and others; (3) the intelligent application of the galvano-cautery.

Having referred to the physiological functions of the nasal passages as the vestibule of the respiratory apparatus, he said that he found that the importance of these was too often lost sight of. In cold climates, it was especially necessary that the nasal mucous membrane should be filled with blood, in order to warm sufficiently the air as it passed over it. In any case in which nasal hypertrophy existed, the first thing to find out was whether this condition was permanent or only temporary; and, if it was permanent, whether the hypertrophy was sufficient to give rise to local and general disturbances. If this was found to be the case, it was necessary to destroy a portion of the hypertrophied tissue; but he strongly advised that as little as possible should be destroyed, as he thought the tendency of the present day was to destroy too much. Cicatricial tissue was always a disadvantage, and if there were too much of it, progressive chronic pharyngo-laryngitis would eventuate.

In speaking of destructive agents, he mentioned, first, mechanical instruments, such as the knife, scissors, and forceps. The forceps, he thought, tore and destroyed an unnecessarily large amount of tissue, and was also very painful. In tumors, the use of the wire snare was much preferable; but in dealing with exuberant mucous membrane, it had not proved efficient in his hands. In regard to chemical agents, he said that when used in a cautious manner, they did not destroy a sufficient quantity of tissue, and, if they were used more freely, they were apt to set up too much irritation.

He preferred to use the galvano-cautery in the conditions under consideration. It possessed the merit of precision, thus enabling the operator to touch with facility the exact spot that he wished, and avoid doing injury to the surrounding parts. The reaction in the adjacent tissues resembled normal vitality more closely than that secured by any other agent. Another great advantage was its painlessness, which allowed plenty of time for operating with deliberation. He had formerly employed Byrne's battery, which served the purpose required quite well, but of late had confined himself to the use of an ordinary thermo-electric pile of zinc and carbon—such as he now exhibited to the Association—which was cheap and always ready, while it furnished all the electric force necessary. In operations with the galvano-cautery about the pharynx, he advised that the soft palate should always be held forward. In conclusion, he urged two points: (1) to injure or destroy as little tissue as possible; and (2) to cut through the neoplasm as narrow a tract as will suffice.

Dr. W. C. Jarvis, of New York, said that he did not believe any means were so precise as the use of the wire and needle, which he had recommended, and which, he regretted to say, were not employed to as great an extent as he had anticipated. No other method, he thought, was so efficient. Pharyngitis sicca had been referred to in the paper as likely to result from the presence of cicatricial tissue; but in all the cases in which he had used the needle, he had yet to see the first one in which this condition had resulted. At the same time, he agreed with Dr. Shurley that too much tissue was often removed. This point seemed to him an additional recommendation for the use of the needle, after which such a result was scarcely likely to follow.

Dr. Seguin said that he had used the snare a great deal, and had never known the dry condition to occur after it. A much better result could be obtained with the needle in the anterior turbinated tissue than by any other means. He was constantly in the practice of using the galvano-cautery also, and in many conditions it constituted the best method of treatment.

Dr. Roe thought that the galvano-cautery was very useful, but also contended that it should be employed with great caution. In cases in which it was applicable, nothing else was so efficient—as, for instance, in hay fever, in which no other agent would answer the same purpose. Different operators, however, were liable to go to extremes in the advocacy and employment of special methods which they had found to be of service.

Dr. Bosworth said that American laryngologists had long labored under a load of precedent which had been brought from the other side, but they were beginning to be more independent of this, and were now in reality doing better work in various departments of laryngology than was being done in Europe.

Dr. Mackenzie said that there was no warmer advocate of the use of the snare than himself, but, at the same time, in many cases he thought it was inappropriate. In posterior hypertrophy it was often impossible to operate successfully with the snare, and here the galvano-cautery could be used with good effect, while for complete destruction of erectile tissue there was nothing so efficient as this. In anterior hypertrophy of the turbinated bone, in which there was an anginose condition, it was also of the greatest possible service, and in granular pharyngitis he agreed with Dr. Shurley that it was the treatment of all others.

Dr. Shurley, in closing the discussion, said that he was free to confess that his failures with the snare and needle were probably due not to the instrument, but to his own lack of skill in using it. Some men got into the way of using special agents with peculiar skill and effect, and this Dr. Jarvis had undoubtedly done in the case of his own instruments; but he thought that others who had not attained this special skill might do much harm with them. In his own earlier practice he was convinced that he had been in the habit of destroying too much tissue with the galvano-cautery, as well as the snare; but this was an error which his later experience had taught him to avoid. In conclusion, he said that when a highly vascular condition was to be treated, there was no method with which he was acquainted by which the amount of tissue to be destroyed could be so nicely regulated as that by the galvano-cautery.

Dr. Beverly Robinson, of New York, then read

A CONTRIBUTION TO THE STUDY OF ADENOID VEGETATIONS AT THE VAULT OF THE PHARYNX.

He said that he did not propose to go into a consideration of the whole subject of adenoid vegetations, but merely to relate some of the results of his own experience in regard to it, and especially in the matter of treatment, which differed from that of Meyer and some other European observers, and of Drs. Bosworth and Swinburne in this country. In the large throat clinics with which he was connected, as well as in private practice, he had met this condition less frequently than the authors referred to; so that, judging from his experience, he could say that it was rare in New York.

After giving a number of statistics in reference to the subject, he related a case which had been under his care at St. Luke's Hospital. The patient was a young, single woman, twenty-four years of age, who, one year before admission, began to be troubled with naso-pharyngeal catarrh. On examination, it was seen that there was a polypus in the right nasal fossa, and in the larynx; the left arytenoid cartilage was found to be congested, while there was an adenoid growth at the vault of the pharynx. This was about the size and shape of an ordinary chestnut, and was removed by Bosworth's modification of Jarvis's snare. There were still some adenoid vegetations left, however, and these were scraped away by means of a Thomas uterine curette. He had yet to meet a case in which the pressure of adenoid growths over the pharyngeal orifice of the Eustachian tube caused deafness, as was so often claimed by other observers. In a case of his own, in which there was considerable deafness, with deviated septum, nasal obstruction, and adenoid growth of the pharynx, the deafness was entirely confined to the ear on the opposite side from that on which the lesions were located. That in twenty-seven out of forty-two cases of adenoid vegetations which Swinburne had reported, there was one affected; and in fourteen of these, perforation of one or both *membranæ tympani* occurred. This frequency certainly did not agree with his experience, and he thought it must be that Dr. Swinburne and he did not agree as to the exact condition to which the name of adenoid vegetations was applied. Voss and other authors had also written of the frequency of the complication of aural complications. He took exception to the considering of follicular pharyngitis as of an adenoid character, although it was true that this condition often existed in connection with adenoid growths. He had not found that the latter were as prone to bleed on being touched as some had represented. In regard to the question of heredity, he agreed with Meyer, that there was this tendency about such vegetations.

In his treatment he had employed Meyer's method with some success, but in sessile growths he had never effected a permanent cure, although he had removed as much tissue as he deemed justifiable. Other cutting operations had never impressed him with much confidence in their efficiency. When cutting instruments were used, however, he thought they should always be guided by the finger, or else with the aid of the rhinoscopic mirror. When this could not be employed, Thomas's blunt wire uterine curette was probably the best instrument to use, as no injury could be inflicted by it on the surrounding parts. A few days afterward it was advisable to make an application of nitrate of silver, or the galvano-cautery. In general, in cases in which Meyer's method could not be used, the galvano-cautery constituted the best means of treatment. It was particularly adapted to sessile growths; while Jarvis's plan was the best for pedunculated growths. In operating for this condition he had not found it necessary to give ether to adults or adolescents. Except in very rare instances, he would employ the galvano-cautery in the case of children, preferring the use of the snare or knife. Having specified some of the details which were of advantage in operating with the galvano-cautery, he remarked that he had yet to see a single case in which inflammation of the middle ear followed its use.

DEAFNESS DEPENDING ON DISEASE OF THE MIDDLE EAR.

DR. S. W. LANGMAID, of Boston, related a case of deafness, believed to be due to non-suppurating disease of the middle ear, and to be permanent, which was completely cured by the removal of an adenoid growth extending from the orifice of one Eustachian tube to that of the other.

DR. MACKENZIE said that he knew of no class of cases in which more brilliant results could be obtained by operative procedures than where deafness depending on disease of the middle ear, which was due to the presence of adenoid growths of the pharynx, was cured by the removal of the latter. These cases, he had found, are exceedingly common among children. The growths were papillomatous, as a rule, and could be snipped off with the forceps. It was his practice to fix one blade of the forceps and use the other as a curette, when, if any of the adenoid tissue remained, he applied strong alcohol to it. It had been debated by some whether such growths should be removed in children or not; but there was no question in his mind as to the desirability of this. If the child were permitted to grow up with them, irremediable changes were liable to occur which would result in permanent deafness. The neglect to interfere in such cases was, therefore, a positive cruelty to the child. He laid special stress on this point, because he believed the condition under consideration to be a frequent cause of deafness in children. As to the etiology of the affection, in the vast majority of instances in his experience it had been due to some local trouble in the vault of the pharynx, usually resulting from one of the febrile diseases of childhood, and the most common of all was diphtheria. The ready bleeding of these growths he considered diagnostic, and hence when a child was presented to him suffering from deafness, and he found that bleeding resulted from the introduction of the finger into the pharynx, he had not the slightest hesitation in pronouncing the case to be one of adenoid vegetations. He consequently differed from Dr. Robinson in his opinion on this point, as well as in regard to the frequency of the affection.

DR. ROE said that he agreed with Dr. Mackenzie that bleeding from touching the pharynx was diagnostic of these growths. He was in the habit of removing them with the forceps.

DR. ASCH coincided with Dr. Robinson as regards the comparative infrequency of the condition, In two large throat-clinics with which he had long been connected, it was surprising how few cases of it were met with. The fact was, however, that patients with adenoid vegetations of the pharynx, as a rule, suffered from very little difficulty. There was some alteration of the voice, perhaps, but it was not of the marked character described by Meyer, of Copenhagen. He had not found it necessary to use the galvano-cautery in this condition.

DR. JARVIS remarked that he had always felt a prejudice against the use of the forceps. The principle of the instrument was a vicious one, and it seemed to him a savage kind of treatment to grasp and tear the tissues in the dark. About three weeks before, there had come to him a patient suffering from carcinoma who had been under the care of another physician, who had removed a portion of the growth with the snare and then used the forceps to remove more of it. Although

he was a skilful operator, the patient had suffered the most excruciating agony during the operation, and the parts had been much mutilated; a long strip of mucous membrane still hanging down into the pharynx when Dr. Jarvis saw him. Dr. Jarvis used a snare with the curette suggested Dr. Bosworth, and removed all the remaining portion of the growth without occasioning the patient any pain. He said that in operating in many cases it was desirable that the soft palate should be held up out of the way by means of a rubber loop.

DR. ROBINSON, in closing the discussion, said that the more he examined throats the less disposed he was to interfere (except in perhaps a very mild way), unless there was no doubt of there being trouble specially due to local conditions present. In half the number of cases operated on, he believed that no good was accomplished and positive harm was often done; and the point which he wished to emphasize particularly in his paper was, that the galvano-cautery, snare, and other violent measures in fifty cases out of a hundred were really of no use.

DR. LOUIS ELSBERG read a paper on

SPASM OF THE GLOTTIS.

This, he said, had been prepared at the special request of the President. Our knowledge of the subject was comparatively recent. The affection in the child had only been recognized within the last two hundred years, and in the adult it was still involved in much confusion, as was indicated by such terms as laryngeal chorea, laryngeal epilepsy, etc., which he trusted would soon be dropped forever from medical literature. The definition was, the spasmodic contraction of one or more of the laryngeal muscles. It might be unilateral (though he had never seen an instance of this), or bilateral, and it might be simple or complicated (with the spasm of other muscles). Again, it might occur in the domain of the superior or inferior laryngeal nerve. There were three varieties, (1) expiratory (including phonatory), (2) inspiratory, and (3) deglutitory. Having given a list of the various synonyms of spasm of the glottis, he passed on to the etiology, and spoke first of the predisposing causes. The most important of these was morbidly increased irritability of the nervous system, and it was on this account that age had so much to do with its causation. The affection was most frequently seen between the fourth and twenty-fourth months of life; but it was a mistake to regard it exclusively as a disease of childhood. In the matter of sex, boys were more subject to it than girls, but in adult life women suffered from it more frequently than men. Heredity had some influence in the etiology, and the general condition played a most important part in this regard. Thus it was most frequently met with in children badly nourished and living in unwholesome and badly ventilated rooms, while among the well-to-do classes it occurred oftener in hand-fed than in nursing infants. It not infrequently came on at the time of weaning, and rachitic children were particularly subject to it. Hydrocephalus and microcephalus also predisposed to it. Enlargement of the thyroid body had been formerly supposed to be the only cause of it, but it had now been shown that it was not a cause at all, although it was quite frequently present in cases in which it occurred. Among the other causes mentioned were hysteria, injuries (especially from food or drink getting into the larynx), catarrhal inflammation of the respiratory mucous membrane, gastric irritation, and emotions, such as anger or fright. In one of his adult patients the trouble was brought on by going up in a high swing, and in a young girl, who suffered from expiratory adductor spasm, it was due to enlarged tonsils.

Then taking up the diagnosis and symptoms, he said that the latter differed according to the set of muscles affected. In abductor spasm there was insufficient closure of the rima glottidis. Dr. J. Solis Cohen had related a case at the present meeting. Adductor spasm was of several varieties: 1. The deglutitory. After swallowing, there was more or less suffocative narrowing of the rima glottidis. The attack lasted less than a minute, and, until the next one came on, the patient could swallow with impunity. Dr. Elsberg had seen one very marked case, however, in which complete spasm of all the abductor laryngeal muscles continued for a week, and the patient was threatened with starvation.

2. Inspiratory. There was closure of the *rima glottidis*, and the trouble might be mistaken for paralysis, which, however, might coexist.

3. In the simple phonatory form there were no symptoms unless the patient attempted to use the voice, when it would be found that the voice had a choked sound; but if phonatory efforts were persisted in, dyspnœa would result.

4. In the simple expiratory form, the attack came on if the patient attempted to whisper, as well as to speak or sing. Nothnagel reported a case in which the spasm was excited by the attempt to blow out a candle; while others had been noted in which the attack was brought on by coughing, and in others, again, by laughing.

5. The complicated expiratory form, or "curious cough." There are two subdivisions of this:

a. As to the mode. The spasm was paroxysmal or continuing. The hacks were not so severe as the cough in the continued form, while they observed a certain rhythm. Both were usually absent during sleep. Chorea was sometimes observed in connection with the trouble, and it was this variety which had afforded the pretext for the characterization of the spasm as "laryngeal chorea," which was, however, a term that could not be too strongly condemned.

b. As to the acoustic quality. This was often very peculiar; the sound might be of a barking, quacking, crowing, or lowing kind; was apt to be very loud and discordant.

6. The complicated inspiratory form. This was the most common and dangerous, and was that ordinarily known as laryngismus stridulus. For a correct and graphic description of this, Dr. Elsberg referred his hearers to the work of Morell Mackenzie, which he said he regretted that he had not the time to quote.

In regard to the prognosis, Dr. Elsberg quoted from the statements which he made last year, and also from Mackenzie, who said that the longer the period of intermission between the attacks, the greater the chance of recovery. The treatment required great promptitude, sometimes operative skill, and always good judgment. In some of the forms of adductor spasm the finger should always be thrust into the throat, to see whether or not the epiglottis was impacted. Catheterization of the trachea was preferable to the performance of tracheotomy as a rule. Time would not permit him to dwell

further upon the treatment; but the ordinary means for relaxing spasm would occur to all.

Dr. E. Fletcher Ingals inquired what sized catheter Dr. Elsberg would use.

Dr. Jarvis spoke in reference to laryngeal growths as being a cause of spasm, and said that he had sometimes observed the tendency to spasm remaining after such growths had been removed.

Dr. J. O. Roe had seen quite a number of cases, which never failed to yield to the inhalation of chloroform. One quite remarkable case had been under his care in which the spasm was due to congestion of the arytenoid cartilage. The patient was not able to swallow solids at all, and only at certain times could swallow liquids. By treating the local condition the tendency to spasm was gradually overcome; but it was a long time before the patient acquired sufficient confidence in his ability to swallow solids to attempt it.

Dr. Elsberg said that on account of the pressure for time his reference to the treatment had been very meagre. In regard to the point of Dr. Jarvis, the latter had not seemed to notice that he spoke of hyperæsthesia of the larynx as liable to induce spasm. The case which Dr. Roe had related answered typically and perfectly to one of deglutitory adductor spasm which he had himself met with. Chloroform he thought was excellent as a rule, except in the case of children, in whom he regarded it as particularly dangerous. In regard to the size of the catheter to be used in the trachea, this would depend altogether on age and size of the patient. The catheters which he employed were the hard rubber ones of Shroetter; and, like the tracheotomy tubes that he used, were of six different sizes. The outside diameter of No. 1, was one-sixth of an inch; of No. 2, one-fifth of an inch; of No. 3, one-fourth of an inch; of No. 4, one-third of an inch; of No. 5, between one-third and one-half of an inch; and of No. 6 (the largest he ever used), half an inch. From birth to the age of one year he used No. 1; when the patient was from 1 to 3 years, No. 2; from 3 to 7 years, No. 3; from 7 to 15 years, No. 4; in women and small men, No. 5; and in large-sized men, No. 6.

The officers were then elected for the ensuing year, as previously reported, and the new President, Dr. Shurley, made a few suitable remarks on taking the Chair. The selection of the time and place of the next annual meeting was left to the Council.

The Association then adjourned.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Thirty-fifth Annual Session, held at Philadelphia, May 14, 15, and 16, 1884.

(Specially reported for The Medical News.)

Thursday, May 15th—Second Day.

Morning Session.

THE TREASURER'S REPORT

was presented and showed a balance of $2451.65.

THE ADDRESS IN MEDICINE

was then delivered by Dr. W. H. Daly, of Alleghany County. The researches of Koch and Pasteur were reviewed somewhat cynically. The practical results, he thought, had been *nil*, so far as the saving of life was concerned. The recent good results in surgery, he thought, were due rather to cleanliness than to antisepsis. He recommended clinical observations in preference to theoretical researches, and cited the discovery of vaccination as one of the triumphs of clinical study.

Dr. E. A. Wood, of Alleghany, thought that the results of the investigations of Koch and Pasteur should not be disparaged. He thought that Jenner's discovery was rather accidental, while those of Pasteur were scientific deductions, and that true scientific education should always be encouraged.

Dr. C. W. Dulles, of Philadelphia, read a paper on

DISORDERS MISTAKEN FOR HYDROPHOBIA.

After calling attention to a previous paper, in which he had suggested the need for an attitude of more careful criticism, and for a fuller acquaintance with the methods by which the true nature of cases of supposed hydrophobia should be tested, the author took up this matter more in detail. He deprecated the common habit of diagnosticating hydrophobia from the symptom of an aversion to drinking. This, he said, is not a characteristic symptom, for it is by no means always present in hydrophobia, and it is often present in other disorders. Yet, unfortunately, it is such a striking phenomenon that it leads observers to overlook other indications which, if properly estimated, would lead to the discovery of the real cause of the trouble. Admitting that all physicians are aware, in a general way, that there is a simulated hydrophobia, they do not know this with precision enough. The cases of this kind are called lyssaphobia, or spurious hydrophobia, but they are not assigned to their several classes as they should be. Even treatises on hydrophobia do not give any adequate idea of the great number of diseases in which hydrophobia may arise as a symptom. To meet this want the present paper has been undertaken.

Dr. Dulles divided the disorders which may simulate hydrophobia into: 1. Disorders of the alimentary canal. 2. Disorders of the respiratory apparatus. 3. Disorders of the circulatory apparatus. 4. Systemic disorders. 5. Disorders of the nervous system.

In inflammations of the fauces, which have been somewhat vaguely classed as angina and cynanche, the difficulty of swallowing has frequently led to symptoms usually considered peculiar to hydrophobia. In such cases, especially when the sufferer is a child or a nervous person, the very importance attached to the act of drinking heightens the disorder, and tends to make it present more and more the picture of hydrophobia.

He next took up the difficulty of swallowing which accompanies inflammations of the œsophagus. After this he referred to that which may arise in inflammations and irritations of the stomach and intestines. The disorders of the respiratory apparatus discussed were the cynanches or anginas before alluded to, then inflammations of the larynx and trachea. Functional and organic diseases of the heart next came under review. Of the systemic diseases in which hydrophobia may be simulated the first considered was rheumatic fever. Uræmia was next spoken of and attention was called to the significance of the assertion that the presence of albumen in the urine is a symptom of hydrophobia. A case was given in which a child twelve and a half years

old, treated for hydrophobia with doses of one-tenth grain of atropia, had "one-third albumen" in the urine. It was also stated that one of the cases from which Dr. Gowers obtained the specimens for his well-known description of the microscopical lesions of the brain and spinal cord in hydrophobia, was probably a case of nephritis. Other less easily classified systemic disorders, which may have symptoms like those of hydrophobia, were then taken up. Of these were various fevers, Dr. Rush being cited as classing hydrophobia as a malignant fever. Several cases in which hydrophobia was intermittent were mentioned, and an article by Dr. Dumas, in which an intermittent fever simulated hydrophobia. The effect of mercurialization as a cause of the symptoms of hydrophobia was then spoken of, and the claim made that some of the older notions as to the nature and course of this disorder may have come from confounding its phenomena with those of mercurial poisoning. In concluding this division of the subject, the occurrence of hydrophobia in pregnancy was alluded to.

Of the disorders of the nervous system, meningitis was first taken up, and dismissed briefly, as being too well understood to need argument. Next it was stated that apoplexy might, in certain of its forms, present symptoms seen in hydrophobia. The same was said to be true of hydrocephalus, and tumors of the brain. Turning to diseases of the brain, which have a more obscure pathology, the author dwelt at some length on the similarity between the symptoms of hydrophobia and those of acute mania. Tetanus was then considered. In this connection the author indulged in a slight digression to deny that the hydrophobia could be attributed to anything "specific" in the saliva of a mad dog, since it was proved that the same effects were produced by the bites of dogs not rabid, and of men, and by a variety of traumatisms.

The simulation of hydrophobia by epilepsy was then discussed, and illustrated. Afterwards hysteria and various psychical states were compared with hydrophobia. This part of the discussion was illustrated with a number of interesting cases. Last of all, the writer spoke of the production of the symptoms of hydrophobia by a variety of narcotic poisons, all of which have been frequently used in the treatment of this disorder. He also intimated that sometimes patients were hastened to their death by the unwise solicitude and management of their physician.

It is the opinion of Dr. Dulles, that the true nature of hydrophobia will never be understood until, as a first step, physicians learn the importance, when called to what seems to be a case of this kind, of rigidly excluding the possibility of the phenomena being due to some other and better understood disorder. To this end he deems it necessary that it should be much better known and remembered what a variety of other disorders may simulate hydrophobia. He does not claim for the present study completeness in its own field, but hopes that it may suggest a line of investigation which, if generally and carefully followed up, will lead to something more creditable to our age than the present ignorance in regard to both the nature and treatment of what is called hydrophobia.

Dr. Traill Green, of Easton, thought there was a great deal of error on the subject. He had seen but one rabid dog, and had never seen a case of rabies humana.

Dr. Arthur van Harlingen, of Philadelphia, then read a paper entitled

THE PRINCIPLES OF EXTERNAL TREATMENT IN DISEASES OF THE SKIN.

The employment of outward applications in the treatment of diseases of the skin has always been largely empirical; a remedy having been chosen in a given case, not with the object of producing a certain desired effect in a known condition of the skin, but because it had been said to be useful in the disease supposed to be present. This "doctrine of specifics" was so prevalent some years ago that but four remedies were commonly employed in skin diseases, namely, mercury, arsenic, sulphur, and oxide of zinc. A disease was either eczema, when arsenic and oxide of zinc ointment was the specific; or it was the itch, when sulphur was to be made use of; or it was syphilis, when mercury was to be employed.

It had occurred to the author that if the more commonly used external remedies could be classified according to their effects upon the diseased integument, certain principles of treatment might be arrived at, which would enable the physician to treat most forms of skin disease according to the appearances presented, without this necessarily involving a knowledge of the nomenclature and classification of dermatology.

He then went on to sketch out a scheme by which the various outward applications commonly employed were arranged according to their effect, as protectives, sedatives, astringents, anæsthetics, stimulants, caustics, and mechanical means of treatment, giving under each head the effects of each class of applications, together with a list of individual medicaments belonging to the class.

The paper was put forth with the hope of suggesting lines of treatment which might aid the general practitioner in the management of the skin diseases encountered in every-day experience.

Dr. J. H. Musser, of Philadelphia, presented a *Modification of the Sphygmograph; being a change in the Base of the Instrument of Pond.*

Dr. J. V. Shoemaker then made some remarks on *Jequirity; its Use in Diseases of the Skin.*

Dr. J. B. Potsdamer, of Philadelphia, then read a paper on

BRONCHITIS AND PNEUMONIA OF RHEUMATIC ORIGIN.

The anatomical seat of this disease, he said, is in the white fibrous tissue of the bronchi, which is inflamed. It does not affect the mucous membrane primarily. Pneumomia is always secondary to rheumatic bronchitis, and may occur in the same lung. Proper rheumatic treatment will often save the patient. Further, it bears a direct relation to rheumatism and rheumatic endocarditis. The prognosis is favorable, provided the disease is recognized early, otherwise the pneumonic process may go on and the patient succumb or the lung may break down and the patient eventually dies of consumption.

The treatment is the same as is indicated in rheumatic affections elsewhere. Salicylic acid and its salts, or phosphate of ammonia, being given when uric acid and urates are found in the urine, and lemon juice when phosphates are present.

Dr. Traill Green, of Easton, followed with a *Plea*

for Chemistry, which he was led to make by seeing some dangerous prescriptions in medical journals.

Afternoon Session.

Dr. Jacob Price, of West Chester, delivered the

address in obstetrics.

He recognized two forms of vomiting of pregnancy. One the slight form, the other "pernicious vomiting." The latter was dangerous in proportion to the time elapsing between impregnation and vomiting. The shorter the time the greater the danger. Pernicious vomiting was always connected with inflammation, congestion, or ulceration of the cervix uteri, or a combination of these. The treatment is by rest and local application of iodine, carbolic acid, and tannin.

The removal of the secundines in early abortion, by instruments, was decried. A tampon would serve as a plug to stop bleeding, when the placenta would be cast off. Forcible dilatation of the cervix was condemned. The danger of post-partum hemorrhage was to be avoided by administering ergot immediately after delivery, and maintaining ergotism for at least twelve hours. Venesection was the best remedy in puerperal convulsions, and thorough antiseptic treatment, including vaginal injections, was advised in puerperal fever.

Dr. J. A. McFerran, of Phila., then read a paper on

obstetrical forceps jointed at the junction of the blades and shanks.

If the forceps hold the head in an unfavorable position, it must continue as it is held if the chin has departed from the chest, thereby lengthening the diameter; there is no possibility of producing flexion to shorten it; if traction be made, there must be unnecessary resistance, and consequent injury. With the forceps fixed to the head, the centre of motion is at the junction of the head and neck, and any flexion possible with the forceps amounts to but little, on account of the short distance between the arch of the pubes and the perineum, and the head swinging in a smaller arc than the handles. The head being fixed, the line of traction must be direct from the point where the force is applied to the point of resistance. No curves in the forceps can avoid this. This direct line is in an oblique direction, approaching more or less the planes of the pelvis, consequently the head is pulled hard against the pubic side, thereby necessitating greater force, the excess being spent upon the tissues of the mother and corresponding parts of the child. Dr. A. H. Smith being fully aware of this difficulty, and the dangerous pressure it subjects the parts to, professes to avoid it by making a lever of the forceps, using one hand close to the vulva as a fulcrum, and making traction at the same time. Dr. McFerran believed his mode of traction to be the best that can be used with the ordinary forceps; still he is fully convinced that it falls far short of producing the desired result. The head is not free, and the force backwards is spent upon the junction of the head and neck, which, if effective at all, would cause extension of the head and would bring trouble in one direction in attempting to avoid it in another. If the perineum and os coccygeus were out of the way, by holding the head back it might be swept out of the pelvis in the manner proposed; still, the other inconveniences would remain.

Traction must be made in an oblique direction, be the shape of the instrument what it may. Admitting that it is evident that the desire to avoid the perineum will cause us to elevate the hands more or less, we thereby depart from the axis of the pelvis, sometimes so far as to lock the head between opposing points; and even when this does not happen, there is a demand for greater traction which involves consequent unnecessary injury. Most of the injuries arising from the use of the forceps arise from pressure, and the mere termination of a labor by delivery is no evidence that injury has not been done. Skill may often avoid much of it, but there is a certain portion that no amount of skill can prevent.

As pressure causes most of the injury, an instrument that causes but little pressure beyond that which necessarily belongs to the case, is the one that should be used. With these facts in view, Dr. McFerran designed a pair of forceps in the fall of 1877, jointed at the junction of the blades and shanks. He has fully tested them on several occasions after the failure to deliver with other forceps, and always with perfect and quick success, and he can now, with a confidence which experience alone can give, urge a trial of this instrument.

It does not require an expert to use this instrument. Anyone capable of making a correct diagnosis in a case need have no hesitation in resorting to it. The complicated combination of ideas in regard to the diameters of the pelvis, and corresponding ones of the child's head, need not confuse the operator. He only needs to know the anatomy of the pelvis and the ordinary size of a child's head. When once the forceps is applied to the head, it is free to deflect, flex, or extend. The line of traction is transferred from the junction of the head and neck to the joint of the instrument. By making the handles a lever and one hand the fulcrum, placed close to the vulva, the head can be flexed and swept down in the axis of the pelvis, and even when traction is made from the extremity of the handles, the joint leaves the head free to deflect and pass an obstruction with the greatest possible ease.

Dr. Mary H. Stinson, of Montgomery County, read a paper on *The Work of Woman Physicians in Asia*.

Dr. Benjamin Lee, of Philadelphia, then read a paper on *Massage; the latest Handmaid of Medicine;* and Dr. L. B. Kline, of Columbia County, followed with a paper on *Diphtheria*.

Dr. H. C. Wood having been invited to make some remarks as to his views on

diphtheria,

said that during the last three or four years Dr. Henry Formad and himself have been occupying their leisure time with investigations into this subject. In the first place, they attempted to impart the disease to the lower animals. They found that when they took material from an ordinary diphtheria, as it prevails in Philadelphia, they failed; but when they obtained material from the malignant epidemic, they succeeded almost invariably in infecting the lower animals. The symptoms were identical with those occurring in man. There were local pseudo-membrane, systemic infection, and death, with the symptoms of blood-poisoning, and the production of a material which was infectious when passed from animal to animal.

They did not attempt to pass it from animal to man.

But nature has done this. Thus, in a Belgian epidemic, a child inoculated some calves in a dairy; the disease was diagnosticated diphtheria and treated as diphtheria, and some of the attendants took diphtheria while swabbing out the throats of the animals. There can be no doubt that it is possible for diphtheria to be transmitted from the lower animals. He is cognizant of cases in which he believes children took diphtheria from cats.

Drs. Wood and Formad took the diphtheritic membrane, soaked it in water, filtered it through clay by pressure, and the filtrate, consisting of liquid but no solid matter, was found to be innocuous. The solid portion left was very poisonous, and did produce diphtheria. They also availed themselves of a natural filter. As is known, the membrane is filled with a micrococcus, a form of vegetable plant, and the urine of a patient with malignant diphtheria swarms with this germ. They found that if pieces of blotting paper were soaked in this urine, they became more virulent than the membrane itself. This seems to prove that the micrococcus is the cause of the disease. They further took the micrococcus and cultivated it away from the body in soups, and they produced diphtheria with micrococci of the fourth or fifth generation; at least, they were unable to distinguish the disease produced from diphtheria. Here, however, is an objection. They found in ordinary saliva a micrococcus or plant which cannot be distinguished from the micrococcus of the most malignant diphtheria; they were, as far as could be discovered, identical, and in everybody's mouth. They noted that there was a grade in the poisoning power. The micrococcus from a sound throat produced no poisoning, and the severity of the poison was directly as the virulence of the epidemic from which the poison was taken. The micrococcus from ordinary throats failed to grow in culture-fluids. From mild diphtheria there was slight power to grow, while from the virulent it grew rapidly. The membrane exposed to the air gradually lost its poisoning power; when it had lost its poisoning power, the micrococcus no longer grew. Dr. Wood thinks that these researches prove that diphtheria is produced by micrococci that are present in every mouth. It fails to produce diphtheria because it is in an inert condition. This will explain the great controversy which has swept over the profession in regard to contagiousness, and the question whether pseudo-membranous croup is the same as diphtheria.

We know there is a mild and virulent form of diphtheria. A child gets an ordinary catarrhal sore throat. Under the stimulus of a plentiful supply of food, the micrococcus begins to grow. At first there is a simple sore throat, but the micrococcus becomes more and more abundant, or, in other words, the inert plant becomes active and there is produced a genuine diphtheria. In other cases micrococci take on the active state outside of the body, and there is generated an epidemic of malignant diphtheria. A child who has developed diphtheria in itself, throws off some of this diphtheritic poison in an active condition, and you have contagious diphtheria. They found that undoubtedly in the majority of cases the disease is local. They injected the diphtheritic poison directly into the blood, but unless there was a local lodgement, there was no diphtheria. They also traced the mode of entrance into the system. The micrococcus first locates upon the mucous membrane and begins to grow, and inflammation surrounds it. The membrane becomes filled with micrococci, these force their way between the epithelial cells, the cells begin to die, and ulceration takes place; the mouths of the lymphatics open and the micrococci pass in. Hence it is that so early in diphtheria the glands of the neck begin to swell. Early you find no micrococci in the blood, but after the constitutional symptoms have become severe, masses of micrococci will be found in the vessels, and the plant invades the white blood-corpuscles. After a time the white blood-corpuscles will be filled with them, and micrococci will be found everywhere present. They are found in the kidney, filling up the capillaries, forcing their way between the muscular fibres of the heart and all over the body, leading everywhere to the destruction of tissue. They also found something which will throw light upon deaths occurring in many instances, and which leads to the conclusion that diphtheria is not a specific disease at all, and it shows that physicians of forty years ago were right, and observed clinically what we are now demonstrating scientifically. Diphtheria is nothing more than a putrid sore throat, a septic sore throat. We took matter from puerperal metritis, from sloughing sores, from gangrenous wounds swarming with micrococci, not distinguishable from those of diphtheria. These we put in animals and got diphtheria.

When they examined the blood in malignant scarlatina they also found this micrococcus. They could prognosticate almost certainly the fate of the patient by noting whether the micrococci were in the white blood-corpuscle or not. A case of scarlet fever seems to be getting better, the original poison has spent itself, but the sore throat which has been produced has caused a condition of debility, the micrococcus has passed into the blood, and the child has perished from secondary septicæmia. Dr. Wood is sure the time will come when it will be recognized that often such a patient does not die from the original disease, but that the original disease has so weakened the vital forces that the system is unable to resist this septic organism which is always about us, and will ever remain with us.

Dr. Benjamin Lee, of Philadelphia, exhibited

A NEW SPLINT FOR HIP-JOINT DISEASE.

A bar jointed at the hip-joint allowing motion in both antero-posterior and lateral directions. It is provided with a rachet, by means of which extension may be made. It is not attached to the shoe, but has provision for adhesive strips which hold it firmly to the foot. Counter-extension is made by a perineal band. He presented a case which he had first seen in the third stage, and requested that a committee of three be appointed to examine the result of the treatment with the new splint. Drs. Allis, Willard, and Pollard, were appointed as the committee. They afterward reported that, with the exception of being unable to flex his leg beyond a right angle, the patient was in perfect condition.

MEDICAL DIPLOMAS.

Dr. Jackson, of West Chester, offered the following:

Resolved, That a committee of seven be appointed to consider the best method of making a diploma, which permits a man to practise medicine in Pennsylvania, an evidence of real worth. Adopted.

EVENING SESSION.

DR. HENRY H. SMITH delivered

THE PRESIDENT'S ADDRESS,

taking for his theme *The Importance and Usefulness of Scientific Medical Organizations to our Profession and the Public*, and he noted their origin and elementary formation, as described in history; showed in what manner our annual meetings are useful to the profession and the public; and alluded to the reciprocal obligations of the public to the profession.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, April 22, 1884.

THE VICE-PRESIDENT, CHARLES MCBURNEY, M.D., IN THE CHAIR.

COMBINED ŒSOPHAGOTOMY.

DR. SANDS exhibited a specimen of stricture of the œsophagus, removed from the body of a child upon whom he had performed the operation of combined œsophagotomy with a fatal result.

The patient was a girl, two years of age, who was admitted into the Roosevelt Hospital, on January 10, 1884, on account of a cicatricial contraction of the œsophagus, which had followed the accidental swallowing of a small quantity of boiling lye, ten months previously. Considerable inflammation was caused by the action of the caustic fluid, and easy deglutition was never reëstablished. Two months after the accident, the child was extremely weak and emaciated, but by the careful administration of liquid food, consisting of milk and raw eggs, her condition was greatly improved.

Treatment by dilatation was commenced in October, 1883, but was soon afterwards relinquished as impracticable. When admitted into the hospital, she was etherized and carefully examined. Nothing abnormal could be discovered by inspection of the pharynx, or by introducing the forefinger, the tip of which passed below the level of the cricoid cartilage without detecting any constriction. Exploration with elastic urethral bougies, however, revealed the presence of an œsophageal stricture, admitting a bougie two millimetres in diameter, which was felt to be firmly grasped. Larger instruments were arrested at the orifice of the stricture, which was situated at a point thirteen centimetres from the central incisor, and presumably just below the upper edge of the sternum. Considerable sickness and nervous depression followed the administration of ether, and the subsequent attempts to dilate the stricture were made without the use of an anæsthetic. These trials were made at intervals of from one to three days, except during a period of a week, when mechanical treatment was suspended on account of a sharp attack of diarrhœa, which rapidly reduced the patient's strength.

Her weight, which, at the time of her admission, was 22 lbs. 13 oz., fluctuated during the following two months, and once diminished more than two pounds in the course of a week. At the end of two months, however, she had gained 1 lb. 7 oz. Meanwhile, in spite of persevering attempts at dilatation, the stricture had become more narrow, and at last impassable.

Soon after this, treatment was commenced, a bougie three millimetres in diameter was inserted through the stricture and into the stomach; at a later period, smaller instruments had to be employed, and these seemed to cause an aggravation of the dysphagia. Three days before the operation, deglutition ceased, and the child's condition became critical. Dr. Sands decided to resort to combined œsophagotomy, which he performed on March 11th, in the following manner. Ether was administered, and the patient's head was extended and rotated toward the right side, a wine-bottle, wrapped in a towel, being placed under the neck, in order to favor extension, as the neck was very short. An incision, extending from the level of the left sterno-clavicular articulation to that of the middle of the thyroid cartilage, was made along the groove between the windpipe and the sterno-mastoid muscle. The inner edge of the latter being exposed, the muscle, together with the carotid sheath and its contents, was drawn outward by a blunt retractor, while the omo-hyoid muscle was detached and held upward. The dissection was then continued in the direction of the œsophagus, being carried along the outer edge of the thyroid gland and tracheal muscles. On dividing the deep fascia, previously held up and rendered tense by a couple of toothed forceps, the œsophagus was readily uncovered, when it was found to be dilated and hypertrophied. It was opened by cutting with a scalpel between two forceps, an elastic catheter having been previously introduced through the mouth. The catheter was then withdrawn; and, the margins of the œsophageal wound being held apart by loops of silk, exploration by means of bougies revealed a tight stricture, situated two centimetres below the episternal notch. After several trials, this was passed by a filiform silver probe, two-thirds of a millimetre in diameter. On withdrawing the probe, it was found possible to introduce a narrow, grooved director, along which a slender probe-pointed eye-knife, such as is employed in slitting up the tear duct, was guided to the orifice of the stricture, where two shallow incisions were made, one being directed forward and toward the right, and the other forward and toward the left. Neither incision exceeded half a centimetre in length, and very little resistance was offered to the knife. No hemorrhage followed, and when the knife was withdrawn, it was found possible to introduce an elastic catheter four millimetres in diameter, which was tied in the wound, the latter being covered with a dressing of iodoform gauze. The operation was almost free from hemorrhage, and neither of the thyroid arteries was divided.

March 11.—11 P.M. Child very restless and weak. Four ounces of milk injected through tube into stomach.

12th.—8.30 A.M. Temp. 103.5°; pulse 135; respiration 38. Patient has passed a bad night, and has failed to rally. Injected milk ℥iv, brandy ℥j. During the day a small quantity of milk and brandy was injected every hour, with the occasional addition of a drop of laudanum. At 6 P.M. temp. 104.8°; pulse 180; respiration 48.

13th.—Patient continued to sink during night, and died at 4 A.M.

Autopsy.—Twelve hours post mortem. The œsophagus was found to be the seat of an indurated tubular stricture, three centimetres in length, the upper end of which was nine centimetres above the cardiac orifice. The œsophageal wall corresponding to the stricture varied in thickness from three and a half to four millimetres, the calibre being four millimetres in diameter.

Above the stricture the œsophagus was dilated to a calibre of fifteen millimetres in diameter, while below the diameter was eleven millimetres. Above the stricture the œsophageal wall was thickened to the extent of two millimetres and a half; below it measured one millimetre and a half. The effects of the action of the caustic were visible throughout the entire length of the œsophagus, the mucous membrane being in many places opaque, white, thickened, and adherent to the muscular coat. Of the two incisions made at the entrance of the stricture at the time of the operation only one had left a trace; this was found to be about four millimetres in length, and extremely shallow, hardly extending beyond the mucous membrane. The peri-œsophageal tissues at the seat of stricture were healthy and uninjured, and no lesions beside those described were found in the thoracic or abdominal organs. An examination of the specimen showed how slight an incision would sometimes suffice to render permeable a stricture which had hitherto proved impassable; and it was greatly to be regretted that the patient had not sufficient strength to survive the shock of the operation, from which she never rallied.

Dr. Sands also presented a second specimen of stricture of the œsophagus, obtained post mortem from a boy thirteen years old, who died from peritonitis following gastrostomy, and upon whom an unsuccessful attempt had been made to perform combined œsophagotomy. The patient entered the Roosevelt Hospital on February 14, 1884, when he gave the following history: About six months previously he was submerged in a vat containing a solution of caustic soda. The injury was severe, causing numerous ulcers of the skin, loss of sight in both eyes, and a stricture of the œsophagus. Soon after the accident the mucous membrane of the mouth began to desquamate, and a week elapsed before he could swallow liquids. A fortnight later he was able to swallow solid food, although deglutition was painful. Three months before admission dysphagia reappeared, and gradually increased until nothing but liquid could be swallowed. Lately, treatment by dilatation had been resorted to, but without benefit. When admitted he weighed seventy-five pounds, and was pale and thin. Examination of the œsophagus discovered a stricture, through which no instrument could be made to pass, situated eleven inches from the central incisors, and nearly opposite the middle of the sternum. On the following day a filiform whalebone bougie was introduced through the stricture and beyond it as far as the stomach. Dilatation was carefully tried nearly every day during the next four weeks, but without success. On one occasion, soon after commencing treatment, the stricture admitted a flexible catheter, three millimetres in diameter. Usually only smaller instruments could be passed, or the stricture was found to be impassable. By careful feeding the patient's weight increased six pounds; it afterwards diminished slightly as deglutition became more difficult.

18th.—Operation—ether. Head extended, rotated to the right, and supported by a hard, round pillow placed beneath the neck. Incision three inches in length, extending from the level of the middle of the thyroid cartilage, to a point opposite the sterno-clavicular articulation. Inner edge of sterno-mastoid exposed, and omo-hyoid divided, to obtain more room. Superior thyroid artery divided between two ligatures. Œsophagus exposed, and opened after being raised by two forceps—a flexable catheter having been previously introduced through the mouth. Margins of wound in œsophagus held apart by loops of silk, while attempts were made to pass the stricture, which was situated three inches below the episternal notch. All these attempts proved unavailing, as no instrument could be made to engage in the stricture, whether inserted through the mouth or through the œsophageal wound. Silver and whalebone probes, including the finest, and elastic and filiform bougies were tried in turn, without success. Oil was injected into the œsophagus, and an endoscopic tube was passed down to the seat of stricture, in the hope of rendering it permeable, but in vain. The wound was irrigated with bichloride solution and dressed with iodoform gauze; the edges of the œsophageal incision having been previously stitched to the integument, with the view of permitting subsequent exploration.

21st.—Patient fed, since last date, by rectal enemata, and is in fair condition. Stricture still remains impermeable to instruments inserted through the wound, although, yesterday it permitted the passage of a fine whalebone bougie (tip 5 F., shaft 8 F.) introduced through the mouth. It was decided to perform gastrostomy. Operation—ether. Incision an inch and a half long, parallel to, and a finger breadth below the inferior margin of the thorax on left side. Outer border of the rectus was divided to the extent of three-eighths of an inch. Bleeding having ceased, the peritoneum was divided and the forefinger passed into the abdominal cavity readily recognizing the anterior wall of stomach. This being drawn forward, was held in position by a loop of stout silk thread, embracing the peritoneal and muscular coats. The stomach was fastened to the abdominal wall by thirteen interrupted silk sutures, introduced through the entire thickness of the latter, but not penetrating the gastric mucous membrane. The operation performed with antiseptic precautions. Irrigation with solution of mercuric bichloride, 1 to 2000. Silk sutures, prepared according to Kocher's method; iodoform gauze dressing. Patient not being very weak, it was decided to postpone opening the stomach so as to favor adhesion. Nutrient enemeta (Tenbe's beef extract) with a tablespoonful of whiskey every four to six hours.

24th.—Surface of wound in the neck looks gray and sloughy. Patient seems to be losing strength. 9 P. M. Removed dressing from abdomen and found wound apparently in excellent condition. Opened the stomach with a tenotomy knife, making very small wound, equal only to width of blade. First attempts to puncture were unsuccessful, the knife passing between the coats of the stomach and not penetrating its cavity. Introduced into stomach a piece of soft rubber catheter, No. 16 F., which filled the aperture completely, and prevented, at the time, leakage of gastric fluids. The puncture, made without ether, caused no pain. A catheter was tied in position and plugged by a wooden peg. Iodoform dressing removed. Four ounces of milk were injected into the stomach every four hours. Rectal enemata continued every six hours.

26th.—Neck wound in bad condition. Applied carbolized oil (1 to 12) and iodoform.

27th.—Abdominal wound looks badly, most of the

stitches having cut through, and the granulations being bathed in secretions which have escaped from the stomach alongside the tube. Inserted a large flexible catheter, No. 19 F., and packed the wound carefully with iodoform gauze. Patient receives by the stomach three raw eggs daily, and eight ounces of milk every four hours.

28th.—Weaker; slight pain in abdomen; no tympanites; wound in neck continues sloughing, and emits a foul odor. Applied solution of chloride of zinc, 40 gr. ad ℥j.

30th.—Died at 11.55 A.M., having failed steadily, and developed symptoms of peritonitis since last date. Elevation of temperature, 101° to 105° was observed from the time of the first operation.

Post-mortem examination showed an indurated stricture of the œsophagus at the point where it had been discovered during life. It measured about eight millimetres in length, and the thickness of the œsophageal wall corresponding to it was four millimetres. The entire mucous membrane of the œsophagus was blanched, thickened, opaque, and adherent. A bougie three millimetres in diameter could be passed without difficulty through the stricture, just above which the mucous membrane was somewhat uneven and abraded, as if it had been injured by the instruments employed in attempting dilatation. No false passage existed, and the tissues surrounding the œsophagus were normal.

The peritoneal cavity contained a small amount of sero-purulent fluid, and the coils of small intestine were adherent to one another by recent lymph. The adhesions between the stomach and the abdominal wall at the seat of the artificial opening, had partly given way, and the evidences of peritonitis were most marked in this neighborhood. The point at which the stomach had been perforated was situated six centimetres from the pylorus. There was no evidence that the stitches had penetrated the gastric mucous membrane.

Dr. Sands was at a loss to explain his failure to pass the stricture at the time when he opened the œsophagus; but the swelling of the mucous membrane, its uneven surface above the contracted orifice, and the lateral position of the wound in the œsophagus, suggested themselves as possible obstacles to success. He regretted his failure, especially in view of the limited extent of the stricture, which was well adapted for cure by internal division. He was inclined to attribute the fatal result of gastrostomy to the low vitality of the patient, which was illustrated not only by a lack of reparative action in the abdominal wound, but also by the unfavorable condition of the wound of the neck. Perhaps, if the final step of the operation had been deferred until a later period, a better chance might have been afforded for firm adhesion between the stomach and the abdominal wall, but the increasing weakness of the patient seemed to indicate that further delay would probably cause death from inanition.

Dr. McBurney referred to a case which he saw about a year ago, occurring in a lady who had had prescribed for her aromatic spirits of ammonia. There was also standing near the bottle another bottle of the same size and shape which contained caustic ammonia, and one night she accidentally took a tablespoonful of the caustic ammonia solution which gave her very great discomfort at the time, but no bad result whatever followed except the destruction of the mucous membrane of the tongue and inside of the cheeks. He supposed the absence of serious results was due in part, at least, to the fact that only a few minutes before she swallowed the caustic ammonia she had taken a considerable quantity of milk.

Dr. Post referred to a case in which the patient accidentally swallowed a teaspoonful of ammonia, which occasioned great distress for a time, but from which he ultimately recovered.

Dr. Yale referred to two cases in which each of the patients had swallowed a drachm of aqua ammonia without discomfort.

Dr. Sands referred to the case of a jeweler who swallowed a mouthful of nitric acid, and died two or three days after admission to the hospital. At the autopsy it was found that the œsophagus for its entire length, and a large part of the stomach, were in a state of gangrene, the slough being quite deep and involving at least the entire mucous membrane. The mucous membrane in the neighborhood of the laryngeal aperture was thickened, but not sufficiently so to cause death from suffocation. The patient also had broncho-pneumonia in both lungs.

Dr. Markoe said he was inclined to think that the efforts made by Dr. Sands in his case, as he had opportunity to witness them, could not have done any mischief in the way of seriously bruising or otherwise injuring the mucous membrane of the œsophagus. He based this opinion partly on the fact that the manipulation was very carefully performed, and partly on the fact that the mucous membrane of the œsophagus does not easily receive injury. He was still more of this opinion in view of a case in which he operated for the removal of a foreign body, in which the forceps were introduced from the mouth, passed down on two successive occasions, and also a number of other instruments, large and small, were introduced, and the foreign body was seized several times and subjected to traction, with an amount of force which he feared had inflicted considerable injury, but at the autopsy no trace of the operation could be seen. At the time that Dr. Sands was operating he was inclined to the opinion that more force could have been used safely.

Dr. Sands remarked that his idea was that the use of the whalebone bougie which was used for several weeks early in the case had possibly diminished the calibre of the stricture.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 1, 1884.

The Vice-President, Horace T. Hanks, M.D., in the Chair.

Dr. Mary Putnam Jacobi read a paper entitled

SOME CONSIDERATIONS ON ENDOMETRITIS,

the main idea of which was that the greater cycle belonging to the uterus—pregnancy, was precisely analogous in its characteristics to the lesser cycle of the organ—menstruation, and that endometritis was always the result of subinvolution occurring in consequence of the inadequate completion of one or of the other of these cycles. Among the propositions that the writer advanced were the following: The endometrium is the

essential part of the utero-ovarian system. The homology of the two cycles of menstruation and pregnancy, as regards the part played by the endometrium, is complete. In either, if the characteristic products resulting from the physiological process are not fully absorbed, subinvolution ensues. Subinvolution, whether dependent on menstruation or pregnancy, is apt, sooner or later, to result in chronic endometritis. Parenchymatous metritis always depends upon antecedent disease of the mucous membrane. Nearly all utero-ovarian disease may also be traced to the germinal membrane of the endometrium. Ovaritis may be regarded as always secondary to fundal endometritis. The same is true, as a rule, of uterine flexions and versions. The cervix may be primarily affected. With the exception of the development of neoplasms, subinvolution is always the cause of endometritis. The utero-ovarian disease is a result of a deviation of the process of growth. The ultimate aim of treatment must be the restoration of the menstrual cycle to its integrity, and for both the success and safety of the means of treatment it is essential to take into consideration the rhythmical element of the cyclical process.

It is very important to recognize the beginning of trouble, and, thus, slight catarrh becomes a matter of great significance. To study endometritis with advantage, it is requisite to understand the factors concerned in it, and the *modus operandi* of their action. It is a recognized fact that tissues of the highest function are the first to become affected in any pathological process, and hence it is the endometrium that is first implicated in the course of utero-ovarian disease. The development of the parenchymatous changes is comparable to the greater cycle, pregnancy.

After alluding to the peculiarities of the vascular supply, she offered the hypothesis that the accumulation of blood in the periuterine and ovarian plexus of veins causes new growths of the normal mucous membrane of the uterus, when, if impregnation of the ovum took place, the decidua vera becomes formed. If not, the endometrium grows, until it fills the cavity of the organ, when it is arrested by pressure; in consequence of which, also, the capillaries rupture, and the hyperæmic condition is removed. By pressure, too, the further growth of the venous plexus is arrested.

Thus, there is a successive hypertrophy of the endometrium, precisely similar to that of the ovarian cortex; and the endometrium and vesicular membrane of the ovary are physiologically united in the most intimate manner. Endometritis, it is true, is not always accompanied by ovarian disease; but it is extremely rare that the latter exists without concomitant endometritis. The reproductive tissues, she claimed, fulfil no function, and, instead of being an advantage to the general system, are the reverse, and require to be repressed; so that there is a constant antagonism between the system at large and the utero-embryonic element. There are three essentials for normal hemorrhage: First, the complete emptying of the venous reservoir; second, the prompt evacuation of the vessels of the endometrium; and, third, that no distention of the uterine veins should remain. If these conditions are not fulfilled, a venous hyperæmia will remain, and when the next cycle of growth commences, thickening of the membrane will occur, because a portion of the new growth incident to the menstrual cycle still remains. From a succession of such processes, chronic endometritis of the catarrhal, vegetative, or other type, will eventually result. Three symptoms were stated to be pathognomonic of endometritis, viz.: First, excessive pain on the passage of a probe into the uterine cavity; second, hyperæmia, as indicated by the hemorrhage resulting from the introduction of the probe; and, third, sensitiveness of the fundus to abdominal pressure. Dysmenorrhœa is a so usually present, especially if the os internum is closed. The existence of such a thing as ovarian dysmenorrhœa, was denied by the writer, who claimed that the pain resulting from ovarian disease reaches its maximum during the week preceding menstruation, and is relieved when the flow came on.

In the treatment of endometritis, it is of paramount importance to recognize the rhythmic character of the uterine function, and the limits of danger, it was believed, are not sufficiently defined. For two weeks before the occurrence of menstruation, the writer held, it is best not to make any intrauterine application, as she considered that after the close of the first week following the menstrual flow, the danger of exciting periuterine inflammation commences.

One of the important results of endometritis is flexion of the uterus, which is caused primarily by softening of the stem of the organ. The uterus is surrounded by a mass of fibro-muscular structure similar to its own, and, indeed, of which its parenchyma is only a more condensed portion. Now the special characteristic of this kind of tissue is the tendency to contract, and, hence, when the uterine stem becomes softened, as the result of endometritis, anteflexion or anteversion may be caused by the contraction of the round ligaments. Retroflexion, on the other hand, is the result of a paresis, the essential prerequisite for which is relaxation of the round ligaments. With retroversion there is also relaxation of the utero-sacral ligaments. Prolapsus depends on total relaxation of all the uterine ligaments.

The essentials of any efficient treatment of chronic endometritis are the destruction of the new products resulting from the continued duration, from the normal process in the menstrual cycle, and the restoration of that normal process. In the first place, therefore, whatever would tend to raise the arterial tension throughout the system, and especially in the pelvic tissues, is of service, and among the agencies of this class mentioned were hydro-therapeutics, counter-irritation, faradization, gymnastics, and the health-lift. Secondly. Local treatment of the coexistent endocervicitis is required. The dissipation of the hyperæmia of the cervix might have such an effect on the endometrium that it would not be necessary to make local applications to that. Thirdly, direct applications to the endometrium. In regard to the propriety and value of such applications a violent controversy has been excited, and different authorities have lauded special agents. The good effects of this procedure in suitable cases, and when properly carried out are, first, destruction of the abnormal growth accumulated; second, contraction of the parenchyma through reflex nerve action; third, compression of the bloodvessels; and, fourth, the moderation of the growth during the succeeding menstrual cycle. The

dangers of intrauterine applications were stated to be: first, the production of uterine cramps; second, the implication of the periglandular lymphatic spaces; third, the production of periuterine inflammation; and, fourth, the propagation of inflammatory trouble to the ovaries. The strong mineral acids, particularly nitric and chromic, are preferred by the writer, as a rule, and it is frequently necessary to dilate the uterine canal by means of tents. Every application to the endometrium is to be regarded in the light of a surgical application, and it should always be made at the home of the patient, who should remain in bed for three days, if a tent has been employed, and for one day, if not. If the application has done good, its benefit will be manifested in the diminution of the leucorrhœa, and in the abatement of the pains in the back and hips; while the next menstruation will be less painful. Intrauterine applications should never be made unless the patient suffers from some form of dysmenorrhœa.

Dr. Mundé thought that it was of the utmost importance to commence the treatment early, since the longer the case progresses the more difficult it is to cure, and the more liability there is to have it complicated with pelvic cellulitis or peritonitis. When the latter conditions are present it is essential, if a cure was to be made, to cure the coexisting endometritis on which they depended; but at the same lime it is not to be forgotten that there is always danger of intrauterine applications setting up additional periuterine inflammation. He differed from the author of the paper in the opinion that parametritis is principally dependent on endometritis at the fundus, as in his own experience he has found it much more frequently associated with disease of the cervix, and he believed that this is due mainly to the fact that the lymphatic connection is more close with the cervix than with the fundus. The same facts are true in reference to ovaritis; so that he is always afraid to treat disease of the cervix if the ovaries are affected.

TEXAS STATE MEDICAL ASSOCIATION.

Sixteenth Annual Meeting, held in Belton, Texas, April 22, 23, 24, and 25, 1884.

(Specially reported for The Medical News.)

The Association convened in the Belton Opera House, and was called to order at 10 A.M., April 22d, by The President, Dr. A. P. Brown, of Jefferson.

The President, in some well-timed remarks, urged that it was the duty of the State to regulate the practice of medicine and surgery. He advocated the organization of a library and museum for the Association, and advocated a National pharmacopœia authorized by the General Government. Upon all these subjects committees were appointed to consider, and report such action as would be to the best interest of the people and the profession.

Dr. R. W. Park, of Waco, in the evening delivered a learned address on *Evolution*.

The President delivered his

ANNUAL ADDRESS

on the second day, giving a graphic *résumé* of the work of the fathers of medicine, showing the honor due them and the exalted position we now occupy as a result of such a foundation of facts in science.

Dr. R. M. Swearingen delivered an eulogy on the life and death of

DR. T. D. MANNING,

who sacrificed his life at Holly Springs during the epidemic of yellow fever in that city.

Dr. T. H. Nott, of Goliad, made some remarks upon the life of

DR. J. MARION SIMS,

and offered appropriate resolutions. On motion, $100 were donated to the Sims memorial fund.

A resolution adhering to

THE CODE OF ETHICS

of the American Medical Association, and approving the course of the New York physicians in severing from the State society and organizing an association in sympathy with the American Medical Association was unanimously adopted.

Bills regulating the practice of medicine and organizing a State Board of Health were presented and discussed and referred to the Committee on Legislation.

In the Sections, thirty-five papers were presented.

Dr. J. M. Willis read the report of a special committee on

THE MINERAL WATERS OF TEXAS,

giving the results of his investigations and inquiries in reference to some of them, notably Wooten's Wells, of Robertson County; Sulphur Springs, of Hopkins County; Lampasas Springs, of Lampasas County; McGregor Springs, Palo Pinto Springs, Sour Wells, and Sour Lake. All of these waters were more or less valuable for various chronic diseases.

Dr. C. M. Trueheart, of Galveston, reported a case of

PERIOSTEUM GRAFTING,

in which he removed the periosteum from a dog and transferred it to a man, with the result of the development of three and a half inches of the clavicle.

Dr. H. W. Dudley, of Hillsboro, read an article on

ANIMAL LIGATURES

made from the "Texas mule-eared rabbit," as superior in finish and elasticity to any he had ever seen.

REPORTS.

Dr. W. J. Burt, as Chairman of the Committee on Publication, reported the printing and distribution of four hundred copies of the *Transactions* for 1883; and, as Secretary of the Association, a prosperous condition of the same, and noting favorable mention from many correspondents and medical journals.

Dr. J. Larendon, Treasurer, reported a balance of $2165

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. H. C. Ghent, of Belton.

Vice-Presidents.—Drs. E. P. Becton, of Sulphur Springs; H. H. Darr, of Caldwell; and M. Matkin, of Hearne.

Secretary.—Dr. W. J. Burt, of Austin.

Treasurer.—Dr. J. Larendon, of Houston.

After which the Association adjourned, to meet in Houston, Texas, on the fourth Tuesday in April, 1885.

CORRESPONDENCE.

TUBERCULAR TUMORS OF THE LARYNX.

To the Editor of THE MEDICAL NEWS.

SIR: In THE London letter to the NEWS of May 17th (p. 597), is a description of the interesting case of tubercular tumors of the larynx, presented at the Clinical Society of London, by Dr. Percy Kidd, who is reported to have "searched literature in vain" for the record of a similar case.

The existence of well-defined, solitary tubercular tumors of the larynx and trachea, occurring independently of ulceration of the surrounding mucous membrane, and histologically distinct from the granular and papillomatous growths so frequently observed in the larynx of the phthisical, was first pointed out by your correspondent in a paper read before the Clinical Society of Maryland (*vide* abstract in *Maryland Medical Journal*, June 1, 1882), and published subsequently in the *Archives of Medicine*. (Tubercular Tumors of the Windpipe; Tuberculosis of the Laryngeal Muscles, etc., *Archives of Medicine*, October, 1882). Prior to that date, such neoplasms had not been described, nor had a case been recorded, the tubercular nature of which had been demonstrated by the microscope.

In the paper referred to, two cases were reported: a growth of the trachea, and a remarkable, diffuse nodular tumor covering the entire vestibule of the larynx, and ceasing abruptly at the free borders of the ventricular bands. Microscopical examination showed the growths to consist of a mass of clearly defined, closely aggregated miliary tubercular nodules, separated from each other by hyperplastic connective tissue, and representing all stages of degeneration. In some, caseation had so far advanced, that microscopic vomicæ were found. The growths seemed to have originated in the submucous tissue, and the nodules in the deeper portions were further advanced in caseation than those which were more superficial. In neither case was there any evidence of ulceration in the upper air-passages.

I am yours very respectfully,
JOHN N. MACKENZIE, M.D.

BALTIMORE, May 20, 1884.

NEWS ITEMS.

CINCINNATI.

(*From our Special Correspondent.*)

MEDICAL COLLEGE OF OHIO.—At a recent meeting of the Faculty of this Institution it was decided to hold a preliminary examination of all candidates for admission, excepting those who can furnish a diploma or other evidence of sufficient literary training. A course of lectures on hygiene was also arranged to be delivered by Dr. Frederic Kebler, now Lecturer on Pathology.

At a late meeting of the Board of Trustees of the College, the Hon. M. F. Force, Judge of the Superior Court, was elected President of the Board, *vice* the Hon. Flamen Ball, who had tendered his resignation, after thirty-five years' service as a trustee, during twenty-three of which he was president. A banquet was given by the Faculty in his honor.

YELLOW FEVER.—There have been twelve deaths from yellow fever at Havana during the week ending May 17. Consular reports from Rio de Janeiro for the week ending March 29, show thirty-three deaths from yellow fever and four from pernicious fever. The consul says: "Though some deaths from yellow fever have occurred from amongst the shipping, the yellow fever has not become epidemic, and there is reason to hope that this port will, for this year at least, escape such a scourge." For the week ending April 5, there were forty deaths from yellow fever and nine from pernicious fever at Rio, and the consul says: "The weather during the week has been cool and pleasant, with frequent showers."

BOWDOIN MEDICAL ALUMNI ASSOCIATION.—The first annual meeting of this Association will be held in Memorial Hall, Brunswick, Wednesday, May 28, at 1 P.M. An address will be delivered by Dr. A. J. Fuller, of Bath, Class of 1841, and a banquet served. A large attendance is already assured.

All graduates of the School who have not received a special notice are requested to communicate at once with the Secretary, Dr. Chas. D. Smith, Portland, Maine.

THE STILLÉ DINNER.—In respect to the memory of the late Dr. Gross, the complimentary dinner to Prof. Stillé has been postponed to June 5.

MCGILL UNIVERSITY.—The annual commencement of this institution was held on March 29th. The degree of M.D. was conferred upon thirty-four graduates.

BISHOP'S COLLEGE.—At the annual convocation of the Faculty of Medicine of the University of Bishop's College, held on April 3d, the degree of C.M., M.D. was conferred upon ten graduates.

NOTES AND QUERIES.

CORRECTIONS.

To the Editor of THE MEDICAL NEWS.

SIR: In the summary of the Report on Vivisection in the May 17 number of THE MEDICAL NEWS, we are made to say that the Indian Government sent money to Philadelphia to carry on researches on serpent venoms. The facts will appear in the report, but I desire at once to correct a statement which would certainly excite comment in England.

Last year, at my request, Mr. Frelinghuysen, Secretary of State, addressed Her Majesty's Indian Government in regard to our researches on venoms. A sum of money was devoted to aid in collecting the poison of Indian serpents, and orders were issued to certain army physicians in regard to the matter. As a result, we have been able to continue the researches which at one time Lauder Brunton was successfully prosecuting, until the Vivisection Act in England put an end to his work.

Yours truly,
S. WEIR MITCHELL,
Chairman.

May 17, 1884.

To the Editor of THE MEDICAL NEWS.

SIR: In your report of the proceedings of the American Laryngological Association, published in THE MEDICAL NEWS of May 17, I am credited with the exhibition of new forms of the tonsillotome and uvulatome. Permit me to plead "Not guilty." The responsibility for these ingenious additions to the pharyngological armamentarium rests with my friend, Dr. Charles E. Sajous, of this city; in justice to whom I would request the insertion of this correction in the forthcoming issue of THE MEDICAL NEWS.

I am, Yours respectfully,
S. SOLIS COHEN.

ORIGINAL ARTICLES.

SCARLET FEVER OF THE FŒTUS IN UTERO, AND OF THE MOTHER AT THE NINTH MONTH OF PREGNANCY.[1]

BY CHARLES A. LEALE, M.D.,
OF NEW YORK.

SCARLET FEVER of the fœtus in utero so seldom occurs that many physicians of extensive experience, and several writers on the diseases of children, doubt the possibility of its occurrence in the unborn child, and intimate that the reported cases are those in which probably a mistaken diagnosis has caused the physician to call the usual redness of the entire skin of the newly born child, a disease which we recognize as caused by a special poison which alone can produce scarlet fever. Having had the sad experience to witness the occurrence of this malignant malady in a young family, a week after the arrival and unpacking of woollen garments belonging to a visiting relative at the time suffering from severe tonsillitis, and who had just left a house in another city, where a recent death followed throat disease and scarlet fever, induced me to warn the profession of the danger, and give a brief review of the literature of this disputed subject.

The New York family comprised the father, aged twenty-five years, the mother, aged twenty-four years, an only child, a son, aged four years, and the monthly nurse, aged fifty years, all of whom were in excellent health before the arrival of a visiting relative who had just left a house where scarlet fever was present, and who, at the time, was suffering from a form of laryngitis we so often see present in those who have been where scarlet fever existed, but yet escape the usual course of the disease.

Of this family the father was the only one known to have had scarlet fever, and subsequently proved the only one to escape, while all the other members of the family passed through the different stages of the disease, the scarlet fever being communicated to the unborn child, who at birth was unmistakably in the midst of the eruptive period simultaneously with its mother, and as the attending physician, for several weeks prior, had not seen the disease, nor had any other member of the family known of it for years in that part of the country where they had resided, it may logically be inferred that the specific *materies morbi* was thus conveyed by this visiting relative, proving fatal to the mother on the third day of the eruption, fifty-six hours after delivery, and nearly so to the fœtus in utero; was very severe in their son; and, subsequently, nearly fatal to the attending aged female nurse.

[1] Read before the New York County Medical Association, April 21, 1884.

The importance of calling attention to the danger of scarlet fever to the parturient woman, received a new impulse when I read in the *Journal of the American Medical Association*, this afternoon, dated April 19, 1884, an article on "Scarlatina as a Cause of Puerperal Septicæmia," copied from another medical journal, and therefore spread broadcast before the profession of the country, where instances are related where a woman was confined in the same bed with a patient having scarlet fever, without the occurrence of any ill effects; also, where a medical man left a case of scarlet fever to attend two cases of midwifery; and another, who, "with hands freely peeling from scarlatina," attended three cases of confinement, and that not one of these cases had anything the matter subsequent to confinement.

The differences between septicæmia and scarlet fever are as distinct as those between measles and smallpox; and the instance to be related this evening, where the mother, infant, and nurse, all contracted scarlet fever, is unlike anything occurring where the originating cause is septicæmia.

The accumulated evidence of a number of European and American observers and writers on scarlet fever, strongly demonstrates its occurrence in the child at birth. Under the name of scarlet fever, however, we do not place those severe forms of septicæmia which produce an eruption of a scarlet character, and are followed by so many of the sequelæ seen after scarlet fever, but include those cases only in which the cause is due to the recognized special influence capable of reproducing a disease of like manifestation, and continuing in successive generations to reproduce a similar morbid condition. Physicians of very large experience have stated that they have never met with a single instance, and refer to articles in print as arguments in their favor, but we who have been brought face to face with epidemic scarlet fever during childbirth, have to respond that experience has taught us the lesson that it does occur, and as it is so very fatal to the young mothers, it is our duty to warn all practitioners of the extreme danger of exposing a pregnant woman to any of the eruptive diseases.

At a meeting of the Obstetrical Society of Philadelphia, held April 3, 1884, Professor Parvin stated that children have been born with measles, but he had not known of such an experience with scarlet fever.[1]

The earliest ages at which Meigs and Pepper[2] have seen scarlet fever well marked was once at twenty-one days, once at five months, and twice at six months, while of the 148,829 cases collected by Murchison from the death returns of Great Britain, 9999, or about seven per cent., were under one year.

Vogel[1] states that very young children are but rarely subject to the fever, and only become affected by it in severe epidemics. In New York City[2] during the past year, 1883, out of a total of 744 deaths from scarlet fever, 67 were under one year old.

CASE I.—Jan. 9, 1875, an otherwise healthy boy was born near the end of the ninth month of intra-uterine life, at about the middle of the eruptive stage of scarlet fever; the entire cutaneous surface was of the dark purplish-red color of the congestive capillary stage of the disease, the mucous membrane of the mouth and fauces was intensely hyperæmic, the characteristic raspberry appearance of the tongue (enlarged papillæ) existed to an unusual degree, and the increased febrile movement and rapid heart-action indicated that life was in danger from the effects of acute blood poisoning. The child at birth weighed nine and a half pounds, avoirdupois, was well developed, but made no effort to inspire. Immediately after birth it was laid on its side, was alternately sprinkled with hot and cold water, then rubbed along the spine; failing thus to induce breathing, and in order to relieve cerebral and hepatic congestion, which was very apparent, about an ounce of blood was allowed to escape from the umbilicus with the immediate noticeable effect of relieving the cerebral and hepatic stasis. The mouth and air-passages of the child were so filled with tenacious mucus that it was impossible to breathe. The nose and buccal cavity were quickly cleansed by a wet towel over the finger, and the accumulation beyond the reach of the finger I drew up by placing a porous towel over the child's face and completely encircling the infant's nose and mouth by my lips, then taking a gentle inspiration, followed by an expiration, which, from the first, was seen to force air into the lungs of the child. This, with pressure on the abdomen and lower part of thorax, together with flagellations to the nates, friction to the spine, was continued for fifteen minutes before the child was sufficiently strong to perform independently the necessary respiratory function.

It was then wrapped in warm flannel, laid on its right side, and at the end of an hour had become sufficiently strong to receive only a superficial bath.

The congestion of the fauces was so great that for the first three days of its life it could only swallow a few drops of liquid at a time. The eruption continued over the entire surface of the body for seven days, the skin at times assuming a dark-purplish color, which would disappear on pressure, leaving a white line for a few moments on the skin, after a finger had been gently drawn over it. At the end of the first week the throat symptoms improved, and the infant was able to swallow teaspoonfuls of liquid food. No diphtheritic exudation followed, and the muscles of deglutition subsequently showed no signs of paralysis.

The period of desquamation commenced about the tenth day after birth, when the cutis of hands, feet, back, and chest exfoliated in many places in pieces of from one to two inches square, and continued to be thrown off for the next week; during this time desquamative nephritis occurred, the urine[1] containing at times as much as one-tenth albumen; general anasarca followed about the fourteenth day and continued for nearly a week. After the subsidence of the œdema, convalescence commenced and continued until the end of the fourth week, when the child was apparently well, and could eat and digest its artificial food as other robust children of the same age. The recovery was complete.

Dr. W. T. Taylor[2] reports a case of scarlet fever in a mother two days after labor, proving fatal in two days. The child lived.

Prof. Louis Thomas[3] mentions two instances where Murchison observed the birth of healthy children by women who at the time were suffering from scarlatina, and that Elsässer also reports that a primipara, twenty-six years old, and already affected with the eruption, bore a healthy boy, concerning whose fate nothing is said, so that he probably recovered, while the mother died four days after.

Prof. J. Lewis Smith[4] states that although cases have been reported of scarlet fever occurring in the fœtus and manifesting itself by the usual signs at birth, yet a clear diagnosis in such instances is necessarily difficult on account of the character of the scarlatinous eruption on the one hand, and the nature of the cutaneous circulation on the other, and concludes that probably in the cases there were errors of diagnosis.

Dr. William C. Roberts[5] in an article on the diseases of the fœtus in utero, in the year 1839, states that scarlatina has never, he believes, been known to affect the fœtus in utero.

"According to Noirot,[6] Baillou, as early as 1574, established the occurrence of such cases; and Ferraris has also published an undoubted case. Tourtual reports the case of a woman, thirty years old, who had never had scarlatina, and who, after nursing her husband and son—both of whom were sick with the disease—during the eighth month of her pregnancy, up to shortly before her delivery, was delivered of a boy on the 19th of September, 1823; the child could not swallow, and had an uncommon redness of the skin, which Tourtual did not hesitate to consider as a characteristic eruption of scarlatina, the more so as also the tongue and mucous membrane of the mouth were of a glistening red color. The difficulty of deglutition lasted to the fifth day when the child drank eagerly, and on the ninth day abundant desquamation commenced just as in older children; later, also, a separation of the nails of the fingers and toes took place; the child recovered completely. During an epidemic of scarlatina a son was born to Gregory on April 23, 1839; the child was clearly suffering from some form of fever, and on the following day had a decided angina maligna without an exanthem, as a result of which the child emaciated and died on May 1. Stiebel tells us that a woman, twenty-five years old,

manifested a very abundant eruption of scarlatina toward the end of her pregnancy; after birth, the child could not swallow for several days, the skin was of a scarlet-red color, and desquamated in larger scales than usual."

According to Hüter, a woman, who four days after delivery died of metro-phlebitis during an epidemic of puerperal fever, gave birth to a child "præclare scarlatina in stadio florescentiæ affectus."

Meynet[1] tells of a woman who, three weeks after the convalescence of her husband and three months after the death of her child from scarlatina, was delivered of a girl, who was somewhat red when born; the redness became more intense on the following day, and the skin felt very hot. These symptoms diminished after a few days, but again became more intense on the thirteenth day; on the fifteenth day Meynet noticed the well-developed redness of scarlatina on the whole body, tongue, and palate; the tonsils were swollen, and there were fever and apparent difficulty of deglutition. On the seventeenth day the redness had almost entirely disappeared, and the general condition was good; but as during the subsequent fortnight desquamation did not appear, Professor Thomas thought the case somewhat doubtful, as also the case of Asmus in which desquamation followed a case of supposed scarlatina of the fœtus, yet he argues that here, although the desquamation was very extensive, it frequently appears in healthy new-born children, in whom there is no suspicion of scarlatina. Asmus's case is as follows: A mother had lost two children towards the end of her pregnancy from scarlatina, and soon after her confinement became dropsical. In her new-born child, who was very much emaciated, the epidermis over the whole body separated in large sheets—from the hands it came off like gloves; the child afterwards recovered completely. Noirot states that Potier observed that a woman "took scarlatina on the morning of the day of her confinement, and died a fortnight after, and that her child, though immediately isolated after birth, nevertheless became affected with intense scarlatina, but recovered completely."

Prof. A. Trousseau[2] informs us that in 1828 he, with Drs. Ramon and Leblanc, were sent by the Minister of the Interior to study the epidemics and epizootiæ prevalent in old Sologne, that part of France which lies between the rivers Cher and Loire, extending from Blois to Gien, and saw occurring simultaneously with severe cases of scarlatina numerous cases of membranous sore throat, and that scarlatina was particularly severe at Cour-Cheverney, a commune situated four miles south of Blois, and it had proved so specially fatal to puerperal women, that even the very poorest were leaving the place and going to Blois to be confined. The district physician informed the Committee that he had lost nine cases. Prof. Trousseau further remarks that puerperal epidemics are very rare in country places, and, generally speaking, pregnant women are proof against epidemic influences, but in thirty-six cases the scarlatinous eruption showed itself in forty-eight hours after delivery, and in a few days the patients died.

Prof. Ernst Wagner,[1] of Leipsig, tells us that during pregnancy everything that is transportable in the mother's blood may be carried to the fœtus, and that in this way the mother's anæmic state may harm the child. Syphilis and smallpox, seldom scarlet fever, measles, dysentery, typhoid fever, intermittent fever, and even tuberculosis and cancer may be communicated to the fœtus. Wagner even goes further when he states that the fœtus may experience several affections, smallpox, for example, without the mother's participation.

The remarkable increase of deaths from scarlet fever cannot be more forcibly illustrated than by reviewing the annexed statistics of the New York Health Department,[2] where we find that for the twenty-five years before 1829, the total number of deaths from scarlet fever in New York was only one hundred and eleven, while we find in the three months of 1829 (viz., October, November, and December) a sudden increase to one hundred and twenty-four, or thirteen more deaths from scarlet fever occurred during these three months than for the entire preceding twenty-five years, an increase which, City Inspector John Coffin states, caused such alarm among the people, that in consequence the medical profession were earlier and more frequently called to treat a disease in which they were "providentially successful," showing that a very large proportion of those attacked recovered.

Hillier states that during the eighteen years from 1848 to 1866, the deaths from scarlatina in London amounted to 52,461, and Meigs[3] and Pepper inform us that for a series of years (1809 to 1868 inclusive) there were 13,016 deaths returned from scarlet fever in Philadelphia.

During the last eighty years, 37,271 deaths from scarlet fever were recorded in New York City, and the slowness of its increase is worthy of notice in studying its epidemic character, for, commencing in 1804, we have 14; never to exceed 5 for twenty years; while only 3 deaths occurred in the year 1824. The remarkable increase in 1829 to 188, and in 1882 to 2066 deaths from scarlet fever, is suggestive of other causes than those due simply to epidemic influences.

During the past twelve years, although we have passed through several severe epidemics of scarlet fever, I have seen only one case in which the disease developed itself in the fœtus in utero (the one mentioned, and which recovered). Yet I have seen three cases of undoubted puerperal scarlatina: two in my own private practice, one as before mentioned having died, while the other recovered after having the most profound symptoms of a severe attack, followed by desquamation of the skin and nails, a complete loss of hair, and a long, tedious convalescence covering several months, but followed by a complete recovery. The third case of scarlet fever at childbirth was in a patient of the late Dr. Peaslee, residing in West 56th Street, whom I was requested to see while she was in

convulsions. She was covered with the eruption, and Dr. Peaslee told me that he considered it an unmistakable case. This patient died on the third day after delivery. Her child died about two minutes after birth; it was remarkably well developed and large, but could not be made to breathe on account of accumulations of mucus in the fauces.

I have in vain endeavored to learn the number of deaths in New York City from scarlet fever during pregnancy and during the puerperal state, also those occurring at birth; but find that out of the total of 744 deaths from scarlet fever in 1883, 67 were children under one year, and 19 in females during the years she is capable of bearing children. The annexed table with a letter from Dr. Nagle of the New York Health Department, was received in answer to my inquiry.

I regret to inform you that I am not able to give you the information you desire. I do not think that physicians are in the habit of adding the word "pregnancy" as a complicating cause of scarlet fever. I take pleasure, however, in sending you a list of the deaths from scarlatina in females between the ages of fifteen and forty-five years, and also the deaths of children under one year old from scarlatina.

Deaths from scarlatina in New York City during the year ending December 31, 1883:

Total deaths from scarlatina, all ages, . . .	744
Total deaths of females between 15 and 20 years old,	6
" " " " 20 " 25 "	4
" " " " 25 " 30 "	6
" " " " 30 " 35 "	2
" " " " 35 " 40 "	1
Total, ...	19
Deaths of children under 1 year old from scarlatina,	67

Case II. *Scarlet fever at the end of the ninth month of pregnancy.*—I carefully examined this lady, aged twenty-four years, when she called at my office, at the end of the eighth month of pregnancy, and found her in perfect health. She stated that she had always been remarkably well, not even having had during her younger life any of the diseases of childhood. She attributed her freedom from disease to the sanitary precautions of her parents, and to the healthful surroundings of her country home in central New York. Her married life had also been exempt from the frequent ills usually incident to pregnancy, and the birth of her first child, which took place at her country home, had not in any manner impaired her health. Her boy, aged four years, also presented all the evidences of perfect health; in fact, when I looked at the father, mother, and son, all in the condition of such vigor, I remarked that surely, with his bright prospects in business, he also had in other respects an excellent commencement in life. But he had removed from a residence in the country, where he always had had an advantage of fresh air, and good, wholesome food, and came to New York City to live in a French flat, where all the sleeping rooms were dark and badly ventilated, the rooms were furnished extravagantly, and the little sunshine was prevented from entering the front of the house by the heavy curtains covering the windows. The rent greatly exceeded that of a pleasant house in the suburbs, but to be near the place of business was the first consideration. The sacrifice to ambition was too great, as subsequent events proved. I heard nothing unfavorable until January 9th, when I was informed that their son, aged four years, was dangerously sick with scarlet fever, and on immediately visiting him, found that his mother also had the eruption commencing to appear on the chest and abdomen, while the mucous membrane of the posterior fauces was intensely hyperæmic. In a few hours her entire body was covered with the eruption of malignant scarlet fever, and the fœtus, from its violent motions, appeared to be in convulsions, thereby causing the anxiety of the mother to be increased to an alarming degree, until she became delirious, when I saw the absolute necessity of quickly delivering her to save either the mother or the child. Gradual digital dilatation of the closed os uteri soon produced the desired effect, and in four hours I applied the forceps, causing an easy delivery of a large boy; the placenta was removed without difficulty, and the moderate amount of post-partum hemorrhage relieved the cerebral congestion to such an extent that the mother was restored to consciousness; the uterus contracted firmly, and careful examination showed that no injury had been done by the induced labor. Improvement continued for the twenty-four hours after delivery, when the temperature again increased, and her skin became of a dark-purple color.

Jan. 10th.—10 A.M. Pulse 160; temp. 105¼° Fah.; resp. 44, very much oppressed; delirious.

10½ P.M. Pulse 142; temp. 105¼°; resp. 48. Skin and mucous membrane dry and purple, kidneys acting well, great prostration from feeble heart-action, and increased delirium.

11th.—10 A.M. Pulse 144; temp. 106½°; resp. 48. Skin of a dark-copper color, excretion of urine abundant, lochial discharge sufficient, delirium increased; the heart's action grew more feeble until exhaustion caused death at 8 P.M., fifty-six hours after delivery. After death the body became black in patches from the extravasation of blood from the ruptured, congested capillaries, her face began to swell, and in a few hours she was beyond recognition, and decomposition rapidly advanced.

The aged monthly nurse was now stricken with the disease. She and the boy recovered, and the house was thoroughly disinfected by the New York Health Department, and no subsequent case occurred there.

Scarlet fever is not nearly so fatal when it occurs more than a week after labor, as when it appears before or simultaneous with child-birth. During the past twenty years' practice, I have observed one such occurrence, when the eruption appeared on the eighth day after labor; in this instance the mother recovered. The infant was not affected by the disease.

Conclusions.—Scarlet fever may attack the fœtus in utero.

The large proportion of children born with scarlet fever recover.

Scarlet fever of the newly born child has like manifestations as when it occurs later in life.

Scarlet fever may attack the woman during pregnancy and also immediately after childbirth.

Scarlet fever is exceedingly fatal to the woman during pregnancy and during parturition.

Scarlet fever rarely, if ever, affects the parturient woman if she has had a previous attack.

Scarlet fever causes death in the parturient woman by coma, exhaustion, or by convulsions.

Scarlet fever being a self-limited disease, is best treated by relieving dangerous symptoms, and in accordance with the rules of hygiene.

Scarlet fever only exceptionally occurs during the ages that women bear children; therefore, the proportion of those liable to contract the disease during pregnancy and childbirth, must necessarily be small.

Scarlet fever and septicæmia are distinct diseases, being unlike in many respects.

REPORT OF A CASE OF ŒSOPHAGOTOMY FOR THE EXTRACTION OF A SILVER FIFTY-CENT PIECE, FOLLOWED BY RECOVERY.[1]

BY FLEMING HOWELL, M.D.,
OF CLARKSBURG, W. VA.

ON March 22d, I was called to Bridgeport, to see Myrtle K., aged eleven, who in playfully attempting to hide a silver fifty-cent piece from her little sister, had thrown it into her mouth; where it had gone beyond her reach and became lodged in the throat.

I found her comparatively comfortable, suffering no pain, except in the acts of swallowing, which came on involuntarily every few minutes. I learned that for several minutes after the accident occurred, there had been great difficulty of breathing, stridulous voice, etc., this, however, at my arrival had entirely passed off. Soon after the accident free emesis occurred, and she vomited apparently as much as she had eaten at the previous meal. I could detect nothing with the finger introduced into the pharynx, though I was able to explore this organ pretty thoroughly beyond the opening of the glottis. With the sound, however, I readily touched the coin, and ascertained that it was over eight inches from the opening of the mouth. With the finger applied externally and pressed down deeply at the side of the trachea, I could sometimes indistinctly feel the foreign substance. By these conjoined manipulations I located the body in the upper part of the œsophagus somewhat below the cricoid cartilage.

As free emesis when the stomach contained considerable solid substance, and before the coin had become so firmly impacted, had failed to dislodge it, I decided it would be useless to resort to this means; but during my manipulations violent retching came on, which I took opportunity to aid by inverting the body, but without any result. I next used the œsophagus forceps, but the coin was beyond the point for the satisfactory manipulation of this instrument. With a blunt hook improvised from a uterine sound, I two or three times got a hold and once very firmly when I used force, gradually increased until I feared I would injure the parts, and hesitated, when the instrument slipped off and I was not able to secure the same good hold again, though the little girl seconded all my efforts with remarkable self-control and determination. Having now exhausted all the resources at hand, and having been forced to the conclusion that an operation would most likely be necessary, I sent for Dr. D. P. Morgan, of Clarksburg, in consultation.

Dr. Morgan arrived about 11 o'clock, P.M. The patient had now had about three hours of quiet rest, suffering no pain except as the involuntary acts of swallowing came on. We at once repeated the efforts at extraction by means of the forceps and hook, and again produced vomiting and retching by our manipulations, but all, as before, to no purpose, and we now together decided that the operation of opening the œsophagus was our only recourse.

The operation of pushing the coin into the stomach was discussed, but our experience had demonstrated to our own minds the impossibility, from its being so firmly impacted, of moving it safely in any direction; and we decided not to incur the risk of putting it beyond the point where it could be readily reached by œsophagotomy. After consulting with the family physician, Dr. J. M. Tate, who concurred with us in our opinion, we were the next morning prepared to do the operation, if matters, in our opinion, still justified such action. We found that our patient had passed rather a comfortable night, sleeping most of the time; but, upon examination, we found the coin still in the same position. We made another effort at extraction, but only to fail again, from spasm of the tube above the foreign substance. I then proceeded to operate in the following manner. I first made an incision through the skin, beginning opposite the upper border of the thyroid cartilage, midway between it and the sterno-cleido-mastoid muscle, and extending downward three inches, or to a point at the anterior margin of the sterno-cleido-mastoid muscle, about two finger-breadths above the upper end of the sternum. By working carefully with the grooved director and knife, the carotid sheath was exposed, which was then drawn outward with a retractor, while the larynx and trachea, along with the omo-hyoid, sterno-hyoid, and sterno-thyroid muscles, and the thyroid gland were drawn inwards. From this point, the coin could be plainly felt, and acted as a guide while dividing the successive layers of fascia, connective tissue, etc., which finally brought us to the œsophagus. During this part of the operation, the utmost care was taken not to injure any of the many important vessels and nerves which lay so near our course, especially the inferior thyroid artery and recurrent laryngeal nerve. The tissues were raised upon the director, and examined carefully before being divided, and we had the satisfaction of reaching the tube without interfering with but a single minute artery; this lay directly across our course, when nearly to the œsophagus, and was divided, after having been secured with a ligature on either side of the wound. The tube having been reached, I made a limited incision upon the foreign substance, introduced a pair of polypus forceps, seized the coin, and then enlarged the incision sufficiently to admit of its extraction. We found the coin, an ordinary fifty-cent piece, with milled edges, lying transversely

[1] Read before the West Virginia State Medical Society, May 22, 1884.

in the œsophagus, its upper edge being about three-quarters of an inch below the lower edge of the cricoid cartilage, and its lower edge somewhat below the upper end of the sternum.

The wound was carefully closed with five very fine interrupted sutures of silk. The ends were cut off close, with the view that the sutures might ultimately readily drop into the interior of the passage.

The external wound was left open nearly an hour, until all oozing of blood had ceased, and the cut surfaces had become nicely glazed over with plasma (a point that my preceptor, the late lamented Dr. H. W. Brock, always insisted on as being of especial importance when union by first intention was desired). After this, the wound was closed in the usual manner, the two ligatures heretofore mentioned being drawn out through the wound, and left in that position to insure a discharge outward in case of any pus-formation.

The after-treatment of the wound was managed upon general principles. For the first few days, we nourished our patient exclusively by rectal injections of beef essence, with beef peptonoids, and almost exclusively so for two weeks. These would relieve hunger in a short time. By the third day, however, thirst became troublesome, and we allowed ice-water to be used, a teaspoonful every hour or so, and by the next day, we allowed, in place of this, a part of the time, iced milk; these were swallowed readily, and without the least pain at any time.

From the third to the fifth day there was a little fever, the temperature rising to 101°, and the pulse to about 100; but beyond this there was not a single unfavorable symptom. The wound healed almost entirely by first intention, there being only a little discharge around the ligatures, which were left to come away almost of themselves, and which they did about the fourteenth day. By the nineteenth day, the wound had entirely healed, and the patient was walking about the town.

MEDICAL PROGRESS.

MALFORMATIONS IN THE FEMALE SEXUAL ORGANS RESULTING FROM ARREST OF DEVELOPMENT.—DR. B. B. BROWNE, of Baltimore, in an interesting paper on this subject, read at the late meeting of the American Medical Association, summarized his conclusions as follows:

1. Nearly all the malformations of the female sexual organs previous to puberty result from arrest of development.

2. As the upper and lower portions of Müller's ducts develop independently of each other, we may find the ovaries developed without the uterus and *vice versâ*.

3. Perfect development of the external genital organs and the mammary glands does not preclude defective development of the vagina, uterus, or ovaries.

4. Entire absence of the uterus or ovaries can only be determined by laparotomy, or by post-mortem examination.

5. A patulous urethra with atresia of the vagina results from arrest of development, and does not indicate that the urethra has been dilated by sexual intercourse through this organ. The patulous condition of the urethra may be the *cause*, but is not the *result* of penetration.

In *congenital* atresia of the vagina, with arrest of development in the uterus, a patulous urethra is the rule; in *acquired* atresia of the vagina the urethra is never patulous, and sexual intercourse never takes place through the urethra.

CURE OF PARALYSIS DUE TO CEREBRAL HEMORRHAGE.—Authorities differ greatly as to the time after an apoplectic attack followed by paralysis, before commencing treatment by electricity. The general opinion is in favor of allowing some time to pass, so as to permit the absorption of the clot and the subsidence of the inflammatory reaction. PROF. DE RENZI (*Rivista Clinica e Terapeutica*, January, 1884), on the other hand, thinks that electricity may be employed, if proper precautions are taken, with the greatest success a short time after the attack, that is, in the first week. To the treatment by electricity he invariably adds other means to prevent the return of the hemorrhage and the development of inflammatory reaction. These consist in the internal use of bromide of potassium, the constant application of cold to the head, and the administration of some drastic purgative whenever there is constipation. The application of electricity exerts an immediate effect on the muscles, which, in the majority of cases, at once regain their contractile power under the influence of the will. S. P. was admitted suffering from cerebral hemorrhage; on the fourth day of the attack, there was complete paralysis of the left leg. Electricity was applied to the muscles of the thigh, and immediately afterwards the patient was able to bend the limb and to raise the knee for some distance from the level of the bed. On the next day, the patient was unable to extend the limb after bending it; electricity was again applied; he then flexed and extended the leg several times without difficulty. On the sixth day paralysis of the toes only remained, and this also yielded to electricity. The application of electricity ought to be practised directly upon the rapid and spontaneous disappearance of the paralytic phenomena, which is usually noticed in the first days after an attack of apoplexy, is arrested. The intensity of the current should be very little, and such that it can hardly be perceived by the observer, touching the rheophores with his fingers wetted in salt water. The interruption of the current must be considerable, the greatest that can be obtained with the automatic interrupting apparatus of the electrical machine. The electrical excitement must be limited to the muscles and intramuscular nerves, therefore the two rheophores must be applied successively for a few seconds to the fleshy parts of the various muscles. The duration of each application is from one to several minutes. The instantaneous action of electricity in paralysis from cerebral hemorrhage is easily explained, by admitting that these paralyses are often neurolytic or suspensive, and that they do not depend on destruction of nerve-elements. The electricity induces in the nerves a negative variation, which extends to the two extremities of the nerve-fibre; so that it overcomes the state of neurolysis determined at the central extremity of the same fibres by the extravasation of blood.—*London Medical Record*, March, 1884.

PNEUMOCELE.

HERNIA of the lung is an infrequent lesion. Its spontaneous occurrence must be placed among the rarest accidents that befall the thoracic viscera. Desfosses, up to 1875, was able to collect only twenty cases, of which seven were spontaneous, the remainder being due to traumatism, such as wounds, fractures, etc. A portion of the lung projects into the neck, or passes towards the surface of the body through some part of the chest-wall, or through the diaphragm into the abdominal cavity. The recognition of the last form during life is impracticable. The pneumocele in other positions may be made out clinically as a soft, reducible, localized swelling, resonant on percussion, and rendered more prominent by coughing. Its usual site is in an intercostal space near the sternum. A case occurring recently in the service of Dr. Malherbe, in the Hôtel Dieu, at Nantes, and published by VIGNARD (*Gazette Medicale de Nantes*, April 9, 1884), is of interest as illustrating the clinical traits of hernia of the lung, and its occurrence in an extraordinary and hitherto unrecorded position.

A stonemason, fifty-two years of age, small in stature, and poorly nourished, entered the hospital February 23, 1884, seeking relief from a bronchitis contracted the previous November. Upon examination, the bronchitis was found to be complicated with a high degree of emphysema, chiefly affecting the right lung. Ten days after admission, he made a false step in descending a stairway, and, immediately following a violent effort to recover himself, he experienced an intense burning and tearing pain in the chest, just above the pit of the stomach. Two days afterwards, the pain still continuing, a slight swelling was observed upon the anterior wall of the chest, in the median line, and toward the extremity of the sternum. This swelling had the form of the segment of a sphere, was about as large as a silver dollar, and elevated "some millimetres" above the level of the neighboring surface. The skin was not discolored. The ordinary movements of respiration had no perceptible influence upon the volume of the tumor; but upon forced breathing, it protruded about half an inch, only to subside promptly when the effort ceased; while efforts of coughing caused a sudden and yet more decided protrusion. This tumor was soft, elastic, non-fluctuating, and yielded a sense of crepitation to the finger. Under moderate pressure it disappeared, giving place to a faint depression, but returned in the course of a few moments, especially if the patient coughed, when there was to be felt a distinct movement of impulsion. When the tension was reduced, there was felt through the integument in the median line and four-tenths of an inch above the point of the xiphoid cartilage, a round orifice, with bony margins, dull below, sharp-cut above, and about one inch and one-fifth in diameter. This seemed to be an exaggeration of the orifice occasionally found in the xiphoid appendix. Percussion over this tumor yielded pulmonary resonance, bounded on the right and below by the dulness of the liver, above by that of the heart, on the left by the clear tympany of the stomach; upwards and towards the right the resonance was continuous with that of the right lung. Auscultation furnished no satisfactory signs. The tumor was the seat of continuous dull pain, aggravated by pressure, by cough, and by effort.

The diagnosis of hernia of the lung was based upon the foregoing characters; of hernia of the *right* lung upon the following data: 1. Propagation of the pulmonary resonance from the tumor in a direction upwards and towards the right; 2. The pain, having its seat in the tumor, radiated towards the right lung; 3. Although the borders of neither lung extend, under normal conditions, to the xiphoid appendix, that of the left lung is much more distant from it than that of the right, which, being in this case emphysematous, had displaced the mediastinal pleura until it reached and pressed against the orifice existing in the xiphoid appendix. The fibrous structure guarding this orifice, yielding gradually to the strain of the lung-pressure, augmented by heavy labor, and more recently by repeated paroxysms of cough, had suddenly given way under an effort more violent than common, and had permitted the border of the lung to find its way through the orifice out under the skin.

Vignard calls attention to the coexistence in the patient of a voluminous, reducible, right inguinal

hernia, as indicating, perhaps, some want of the normal resistance of the fibrous tissues.

THE DANGER OF CANNED GOODS.

The bill introduced in the New York Legislature, requiring all goods sold in the State to have the date of packing stamped on the can, implies a danger of impairment in the purity of goods packed for an undue length of time, in regard to which the public should be properly cautioned and protected. The requirement appears to be reasonable, apart from its bearing upon the question of health. The proposition has excited considerable comment and opposition upon the assumption that its adoption will be injurious to a large mercantile interest. How this can be is not clearly apparent. It has been suggested that before legislating upon the question, it would be wiser to have the whole subject of the alleged dangers to health from the use of canned goods thoroughly and impartially investigated, so as to furnish results upon which to base intelligent action.

There is already a suspicion in the public mind, that canned goods are not free from danger, and reports in the newspapers of cases of sickness supposed to have been due to this cause have tended to confirm it. Some more tangible evidence, however, is required, before the passage of laws which might destroy the sale of cheap foods and injure a prosperous industry.

Tin has frequently been found in canned articles of food, as attested by the investigations of Menke, Hehner, and Blyth. Recently, Drs. Ungar and Bodländer of Germany, have examined a number of cans of vegetables and fruits, and in every instance found tin in the solid portion of the contents in the form of an insoluble stannous compound. The percentage of the impurity—calculated as metallic tin—was very small, in no case exceeding 0.04 per cent.

At a meeting of the Pharmaceutical Society of London, held March 5, 1884, Professor Attfield read a paper on the subject of tin in canned foods, in which the results of a large number of examinations, including sixteen varieties of food, were detailed. In only a few instances were traces of the metal found, and the proportions were so exceedingly small as to be undeserving of serious notice. He remarks that it is just possible that in the early days of canning a little stannous, plumbous, or other chloride might have been found in canned food as the result of the use of "spirits of salt" in soldering, but such a fault has rarely been detected of late years. A harmful quantity of a soluble compound of tin would render the flavor of the food so disagreeably metallic as to prevent its use after being once tasted. In his opinion, given after a long experience and an examination of all the evidence at hand, "the public have not the faintest cause for alarm respecting the occurrence of tin, lead, or any other metal in canned foods."

It is not intended to convey the idea that canned food is never injurious to health; but when harm has been done, it is in all probability due to the food, and not to the can. When food is allowed to remain long in an opened tin, there is no doubt that it may take up portions of tin, iron, or other metal, but such an accident is the result of gross carelessness, and not of a fault in the process of canning.

The other side of the question is presented by Dr. Johnson in a paper read before the New York Medico-Legal Society in April last. He cites several cases of corrosive poisoning supposed to have been due to muriate of zinc and muriate of tin, derived from the use of the "muriate of zinc amalgam" in soldering cans. This method is said to have been extensively used. The State of Maryland has a law prohibiting the use of this flux, because it is considered a dangerous practice. We are informed from another source that this soldering flux, consisting of a solution of muriate of zinc, is still quite commonly used in canning factories in the place of rosin flux, which is more troublesome, but harmless. Though every care is said to be taken in its application, it is undeniable that the substance is poisonous, and therefore a risk of injury attends its use.

The French Commissioner of Hygiene admits a possible cause of lead-poisoning from food which has come in contact with solder or with surfaces covered with an alloy containing lead; and he suggests that makers of cans be prohibited from soldering on the inside of such cans, or to employ in their manufacture any but the best quality of tin. What is known to the trade as "seconds," or doubtful or "reprocessed" goods, are in the market, but are not dealt in knowingly by any reliable firms. The appearance and taste of such goods should cause them at once to be rejected by sensible people. With such articles, the attempt at preservation has been a failure, and their unwholesomeness is due to the admission of air and resulting decomposition.

There is scarcely any doubt as to the wholesomeness of food preserved in tin when due care is observed in the use of only a pure article of tin, and in the preparation and sealing of the cans. It is to the interest of those engaged in the business of canning, to see that these important particulars are scrupulously carried out, and we believe that most of the products placed upon the market will stand the test of a searching examination. It is also apparent from what has been said, that canned goods are exposed for sale which it is unsafe to use on account of the objectionable methods of preparation and quality of the food itself. The public are not always able to

discriminate; hence the want of confidence in the purity of these foods as a class.

In view of the conflicting opinions which prevail, and the importance of the subject, it would be a benefit, as well to the honest producer as to the consumer, to have a commission of inquiry appointed to investigate thoroughly and impartially the question in all its relations, so that, if necessary, proper legislation could be secured in behalf of the public welfare. The National Board of Health would have been the proper authoritative body for conducting such an inquiry. In lieu thereof, the work might be safely entrusted to one of the more active State boards of health.

TIME OFTEN AN ESSENTIAL ELEMENT IN THE DIAGNOSIS OF PREGNANCY.

IT was remarked by one of the old medical authorities that the physician's reputation is never in greater peril than in the diagnosis of pregnancy. We may add that probably more avoidable errors are committed in this diagnosis than in any other department of medicine. One great source of error is in hasty judgment—giving an immediate opinion when a few weeks' delay might reverse it, or secure its unequivocal confirmation; this disposition to decide at once in cases of possible pregnancy is sure to bring a man to grief, and possibly to disgrace, sooner or later. Very often in the reports of cases that are being tried, we read at the close, "Judgment reserved." In medical practice the physician ought to write down after his record of some of his cases, especially of some of those in which the diagnosis of pregnancy is to be made, the same words. Time is the great revealer of secret things; the asserted pregnancy which, like the weaving of Penelope's web, never ends, as well as the denied pregnancy, which, a few months after the denial, is proclaimed by an infant's first cry, often bears testimony to professional errors that disappoint if they do not disgrace. How much better it would be, unless the evidence be beyond all cavil or doubt, to wait a few weeks, or even months, until the proofs become conclusive, than to commit such errors.

Pajot urges, in his *Clinique d'Accouchements*, the importance of such delay, and relates a case which he had recently seen. A lady, in her first labor, had such injury that a vesico-vaginal fistula resulted. Subsequently she had two other confinements, when her husband died. She remarried, but never had coition without a sponge being in the vagina. This was constantly worn, partly as a support to the uterus, and partly to receive the discharge which escaped from the bladder. Uterine enlargement, and then, as she believed, fœtal movements, led her to consult Pajot, who, failing to hear the fœtal heart, or to discover in the cervix the usual changes of pregnancy, declined to give an opinion. Her menstruation continued, in spite of the enlargement, as she thought, from pregnancy. By Pajot she was referred to a distinguished Paris surgeon and accoucheur, who decided that she had an ovarian tumor, and desired to puncture it. The patient, frightened at this decision, wished to consult "*le prince des kystes de l'ovaire*," and Pajot took her to him. He, after a careful examination, neglecting, however, auscultation, decided she had a large uterine fibroid; the mortality was very great—70 per cent.—but he would operate in three months if the family desired it. Three weeks after this examination she gave birth to a child of between seven and a half and eight months, and, of course, the tumor was gone. With Pajot we may well say that in such cases time is the best of all means of diagnosis.

PRIORITY IN THE REDUCTION OF CHRONIC UTERINE INVERSION.

IT is somewhat remarkable that the late Dr. J. P. White, in his paper upon chronic inversion of the uterus, presented to the International Medical Congress held at Philadelphia in 1876, made no reference to the successful reductions prior to his own, and to that of Dr. Tyler Smith. That of the latter was in September, 1856, though not published until April, 1858; the inversion was of twelve years' standing. Dr. White's first case was in March, 1858, the inversion had existed for six months, and the report of the operation was published in THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES for July, 1858.

But Canney, in January, and Barrier, of Lyons, in March, 1852, each reduced a chronic inversion, in one case six, in the other fifteen months after the occurrence of the accident. Denucé, in his recent *Clinical Treatise upon Uterine Inversion*, Paris, 1883, refers to these two cases, and gives in full an earlier case, also in the practice of a French physician. The operator in this case, occurring in 1847, was Vitry; the inversion had lasted sixteen months, and the success was obtained by using ether until complete anæsthesia was produced, and then the reduction was effected by taxis, counter-pressure being made at the hypogastrium. Denucé remarks that the discovery of reductions of chronic inversions was delayed because the previous discovery of etherization was necessary. But it should be remembered that one of the successful modes of reduction, that which is due to Tyler Smith, by continuous elastic pressure, does not require an anæsthetic. Nevertheless, Denucé's remark is true as to reduction by taxis, for in it the use of an anæsthetic pushed to such a degree that all contraction of the uterus and of the abdominal muscles is abolished, is necessary for success.

SOCIETY PROCEEDINGS.

THE AMERICAN MEDICAL ASSOCIATION.

Thirty-fifth Annual Meeting, held at Washington, May 6, 7, 8, and 9, 1884.

(Specially reported for THE MEDICAL NEWS.)

SECTION ON OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

WEDNESDAY, MAY 7TH—SECOND DAY.

DR. J. F. FULTON, of Minn., read a paper on

THE INFLUENCE OF CLIMATE ON THE TREATMENT OF CATARRH OF THE MIDDLE EAR.

Referring to the fact that non-suppurative disease of the middle ear forms one-half, at least, of the cases that come to the aurist, and enlarging upon the suffering often entailed by it on the patient, resulting sometimes in suicide or insanity, he stated that after all other means had been exhausted, the influence of climate should be brought to bear. In some instances, after all else had failed, a change of climate had effected a complete cure.

Heroic treatment by strong solutions of caustic potash and soda had been discarded, but modern otologists had retained the principle of *stimulating* in a milder way this form of ear disease, and the effect of a cold, stimulating climate upon such cases was very beneficial, and might be compared to the effect of the same climate upon the early stages of phthisis, before suppuration had taken place. An analysis of 50 cases sent to St. Paul, Minn., with the same number treated in Pennsylvania, gave for the more northern locality 18 cures, 20 improved, and 12 unimproved, against 4 cures, 9 improved, and 37 unimproved in those treated in Pennsylvania. The dryness of the atmosphere was a great factor in the beneficial effect. The absolute humidity is very low, and the relative humidity is ten degrees lower than the average in any eastern State.

He gave the history of a case of a severe type, in which deafness was so great that the watch could only be heard by contact, and in which severe nasal catarrh was present. Six months in Pennsylvania under treatment gave no improvement, or only temporary results. A transfer to St. Paul was followed by relief of all the distressing symptoms, and greatly improved hearing. The best results were in cases originating in foreign countries, while those proved most obstinate which originated in this country.

In the discussion on this paper, DRS. SEILER, WILLIAMS, and others believed these results to be in accordance with facts as noticed by them.

DR. WILLIAMS said that he would be glad to send all his patients afflicted with "dry catarrh," as it was popularly called, to any climate holding out hopes of a cure.

DR. L. TURNBULL, of Phila., defended the Pennsylvania atmosphere from the charge that all parts of the State were inimical to the cure of this form of ear trouble.

DR. D. N. RANKIN, of Penna., read a paper on

EPISTAXIS.

The nature and history of this obstinate affection were described, particularly the hereditary form, now considered a form of hæmophilia. A rheumatic diathesis generally accompanies this form, but its pathology is still uncertain. Examination of the blood of patients has given negative results. A case was mentioned in which eighteen pounds of blood had been lost in thirty-six hours. He then related the history of several cases which had come under his treatment. After checking hemorrhage by plugging or the galvano-cautery, he used ergotin, iron, and quinine internally for several months to combat the constitutional tendency.

DR. BROWN, of Ohio, mentioned a family of twelve members all afflicted with the hereditary form of epistaxis, some of whom came under his care. Watery extract of witch-hazel, in teaspoonful doses, had produced good results.

DR. W. S. LITTLE, of Pa., read a paper entitled

A TEST-CARD OF WORDS MADE UP OF LETTERS CONFUSING TO THE ASTIGMATIC EYE; REMARKS ON ASTIGMATISM.

He desired, he said, to bring to the notice of the profession a test that will exhibit manifest defects more markedly, and bring out more latency than do many tests; the recognition of optical defects, especially those produced by astigmatism. The letters in Snellen's type, and in other letter-types, will exhibit the defect by the way the person tested expresses the name of the spherical and right-angled letters, *O* is called *C* or *G*; *F* is called *P*; *B* is called *S*; or *vice versâ*.

In simple myopia or hypermetropia the distortion does not occur, but obliteration of the letter of a given size at a given distance. This fact has been recognized. He has devised a test based on the distortion and confusion of letters, and after a prolonged trial finds it especially useful for the general practitioner.

The letters most frequently distorted have been selected from Snellen's type, and formed into a word; underneath this word has been placed the letters of the same word as they appear to the astigmatic eye; they say the letters in the word and in the line underneath the word are alike. To give an approximate mathematical expression to the degree of the defect, the size of the letters are graded from D. = 18 to D. = 6. Four letters in the word and four letters in the confusion-line below. The word *FOOL* has been selected, underneath it the same sized letters graded, are the letters *PCCI*, which are taken for the letters in the word *FOOL*.

Tested at six metres, the last letter in the worded line underneath being D. = 6, *F* is called *P*, each *O* is called *C*, *L* is called *I*; the whole word distorted at six metres, 1 D. or more of astigmatism exists. If the last three letters are distorted in *FOOL*, and called same as last three letters in line underneath, 0.75 D. of astigmatism exists; the last two letters so affected, 0.50 D. of astigmatism exists; the last letter, 0.25 D. of astigmatism. In simple myopia or hypermetropia of 1 D., the letters in each line are lost or obliterated, but no distortion, or confusion, or likening of each letter in each line under one another occurs as in astigmatism.

To obtain the position of the good and bad meridian in astigmatism, the horizontal lines, one over *FOOL*, the other under *PCCI*, will enable this to be found. The size of the lines is D. = 9. They can be held horizontally, vertically, or obliquely to either side. Tested at six metres, if both are seen distinctly horizon-

tally, they are not vertically; or the reverse, according to the axis of the good or bad meridian. The same holds when held at any angle—astigmatism existing. In astigmatism higher than 1 D., the same type can be brought nearer, or the word *NULLIFIED*, in type from D. = 60 to D. = 4, can be used. In letters over D. = 6, defect higher than 1 D. will be exhibited.

While the test is useful for the diagnosis of optical defects, it answers the purpose as well for correction of these defects with glasses, and for proving work done by other valuable and necessary tests at the hands of the ophthalmic surgeon.

Dr. J. L. Thompson, of Indiana, protested against that portion of the gentleman's remarks which seemed to inculcate a disuse of mydriatics in the examination of the eye for all defects of vision. He was satisfied from the examination of those patients who had previously been under the treatment of other practitioners, that the most eminent men sometimes made "the most horrible mistakes," from neglecting to dilate the pupil.

Dr. Reynolds, of Louisville, referred to the importance of determining as nearly as possible the exact *meridian* of the astigmatism.

Dr. Samuel Theobald, of Baltimore, said that in one-half of the cases that came to him, he used no mydriatic, with just as good results, and desired to put himself on record as opposed to their indiscriminate use.

Dr. Shakespeare, of Philadelphia, said that he did not believe it possible to determine the nature and degree of astigmatism without mydriatics.

Dr. S. D. Risley, of Pennsylvania, believed in dilating the pupil "in the vast majority of cases."

Dr. Connor, of Detroit, and others, gave their views, the preponderance of sentiment being apparently decidedly in favor of the use of mydriatics in all cases except when age makes it unnecessary, or glaucoma is threatened.

Dr. Little said that he was a full advocate of their use except in such cases.

Dr. Laurence Turnbull, of Pennsylvania, then read a paper on the

DISEASES OF THE EAR IN LOCOMOTIVE AND OTHER ENGINEERS, FIREMEN, AND CONDUCTORS, WHICH MAY ENDANGER THE LIVES OF THE TRAVELLING PUBLIC.

The prevalence of a greater or less amount of deafness among railroad employés was dwelt upon, and the result of experiments made upon the hearing of men so engaged was given, and the author concluded by suggesting that legislation should be called for to insure a *maximum*, not an *average*, degree of hearing on the part of those who took the lives of the public into their hands.

Dr. C. M. Hobby, of Iowa, gave a

PRELIMINARY REPORT UPON THE CAUSES OF BLINDNESS.

These were conclusions drawn from the United States Census and one hundred and fifty-two cases of blindness, all of the latter being pupils of a college for the blind. The separate lesions were classified according to age, sex, and, so far as practicable, to causation. Among causes, ophthalmia neonatorum constituted but twenty-six of the total, thus contradicting the assertion on the previous day by a gentleman, that it caused more than half of all cases of blindness. His experience showed that twenty-five per cent. of all was congenital blindness, and seventeen per cent. more before one year of age or forty-two per cent. under one year, but the United States Census gave different results. He gave as his opinion from his own observations that "it is safe to infer from the cases noted that marriages of consanguinity had no effect on the vision of the children."

Dr. C. S. Bull, of New York, then read a paper on

THE METHOD OF HASTENING THE GROWTH OR RIPENING OF CATARACT.

This was Fœrster's operation of broad iridectomy, followed by a rubbing or massage of the cornea. Fœrster had seen no iritis following on the operation in one hundred and fifty cases. The writer *has* seen this ensue, but it was a mild form, and amenable to treatment.

Dr. Joseph A. White, of Richmond, said that he had operated in this way in only three cases; the effect of the massage was to produce an opacity of the cornea which remained for six months after the operation.

THURSDAY, MAY 8TH—THIRD DAY.

Dr. E. F. Ingals, of Chicago, read a paper on

NASO-PHARYNGEAL FIBROMATA.

He exhibited a snare such as he was in the habit of using for their removal. Four cases were described in which tumors were removed by this instrument, or by its use conjoined with the galvano-cautery. He believed that when the stump of a tumor was thoroughly cauterized, its return was much less likely to occur.

Dr. F. H. Bosworth, of New York, said that he had removed growths where the employment of the galvano-cautery had been productive of infinite mischief, and of all forms of cautery he considered that the most injurious. He would like to see the profession get rid of the idea of "roots" to these growths. There were, in fact, *no* roots.

Dr. Turnbull agreed with Dr. Bosworth as to the injurious effects of the galvano-cautery.

Dr. J. N. Mackenzie, of Baltimore, read a paper on

THE EFFECT OF CHROMIC POISONING ON THE NOSE AND ADJACENT CAVITIES.

He described the frequent occurrence of ulceration, sloughing, and final perforation of the septum nasi in workmen engaged in the chrome works in Baltimore, the whole attack frequently running its course in forty-eight hours or less. These cases were *not* due to syphilis or other constitutional disease, but were directly traceable to the effect of inhalation of bichromate of potash, the fine particles of which permeated the air of the establishment and set up the inflammation described.

Drs. Turnbull and Bosworth took part in the discussion of this paper—the latter holding that, except in a few rare cases, molecular death of the part, and perforation of the septum following on ulceration, are always due to constitutional taint.

Dr. F. H. Bosworth, of New York, read a paper on a case of

ROUND-CELLED SARCOMA OF THE PHARYNX AND SOFT PALATE, WITH EXHIBITION OF THE PATIENT,

who, by his ruddy complexion and general appearance of health, would not have been suspected of ever having

undergone such a series of operations as were described. The origin, growth, repeated removal, and final extirpation of the growth were described, together with the profound weakness and cachexia which the patient exhibited towards the last, his life having been despaired of at one time. The fragments of the tumor were also exhibited in a bottle of alcohol. Since the final operation, in November, 1882, the patient had enjoyed excellent health. He stated that in this case he had first used the galvano-cautery as being an orthodox instrument, but discontinued it as soon as he saw the injurious effect it produced. He now believed it to be an ingenious instrument, possessed of much *moral* weight in its effect on the patient, but more frequently doing more harm than good, and had not used it for eighteen months. The members were then invited to examine the result of the operations as seen in the patient, who was present.

DRS. ROE and MACKENZIE defended the galvano-cautery, as sometimes filling the requirements better than other instruments.

DR. BOSWORTH objected to the uncertainty of its action, owing to our inability to control the degree of heat. The pain produced by the instrument was also an objection. A bit of chromic acid would give as much caustic effect, with but a trifling amount of pain as compared with the galvano-cautery.

DR. UHLER, of Maryland, then gave an exhibition of

INSTRUMENTS AND MODELS OF INSTRUMENTS FOR THE REMOVAL OF TUMORS.

He showed several models of corkscrew-like instruments for extracting tumors, and said that a veritable corkscrew was frequently useful as an adjunct. He also exhibited a small pasteboard model of an operating-table on which the patient lay on an inclined plane, the surgeon being under the table.

DR. E. C. MORGAN read a paper on

APHONIA DUE TO CHRONIC ALCOHOLISM,

in which he argued that alcohol should be classed with lead, opium, and other poisons as an occasional cause of muscular paralysis of the muscles concerned in speech.

DR. ROE then read a short paper on

SOME CASES OF TRACHEOTOMY,

which contained some statistics, and the report of a successful tracheotomy on a child seven months old, which was suffocating from a foreign body in the trachea.

The Section then adjourned *sine die*.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Thirty-fifth Annual Session, held at Philadelphia, May 14, 15, and 16, 1884.

(Specially reported for THE MEDICAL NEWS.)

FRIDAY, MAY 16TH—THIRD DAY.

DR. JOHN L. ATLEE, OF LANCASTER.

DR. R. J. LEVIS, of Philadelphia, offered the following:

Resolved, That the members of the Pennsylvania State Medical Society, hearing of the illness of their distinguished and venerable colleague, Dr. John L. Atlee, of Lancaster, they desire to express to him their regret at missing him at their meeting, and their warm wishes for his recovery, and for a long continuance of his honorable, energetic, and useful life. Adopted.

THE ANATOMY ACT.

DR. JOSEPH LEIDY, of Philadelphia, presented the following:

Resolved, That the Medical Society of the State of Pennsylvania, recognizing the importance of anatomy, and duly appreciating the recent Acts of Assembly making provision for efficient distribution, recommends the members of the medical profession throughout this Commonwealth to encourage and assist the Anatomical Board in carrying out the provisions of said Acts.

DR. J. EWING MEARS seconded the resolution, and remarked that the Acts were safeguards against grave-robbery, and if strictly enforced there would be enough dissecting material for all educational purposes. The great need was an enforcement of the law outside of Philadelphia County. If all counties would send the bodies as the law required, there would be no trouble in regard to the supply. The resolution was unanimously passed, and the Secretary was instructed to send a copy to each county Society.

Dr. William S. Little then delivered the *Address in Ophthalmology*, taking for his subject *The Value of Pupillary Symptoms in General Disease—an Analysis of One Thousand Cases*.

DR. EDWARD JACKSON, of Chester County, then read a paper entitled

ALARMING AND DANGEROUS DOSES OF THE MYDRIATICS,

based upon a study of two hundred and fifty reported cases of mydriatic poisoning, in which he attempted to point out the dose at which liability to a fatal result began. The mydriatics being almost always used in very small doses, say one-sixtieth of a grain of atropia, or an equivalent of other mydriatic preparations, practitioners are liable to come to regard such a dose as near the maximum that it is commonly safe to give; and such an idea is apparently supported by the fact that the symptoms of mydriatic intoxication are very liable to appear after the administration of any larger dose. A study of the literature of the subject, shows that such an idea exists without a good foundation. Among all the cases, the reports of which had been examined, but seventeen had terminated fatally.

The conclusions reached were: For adults, the minimum fatal dose of atropia is certainly not less than the minimum fatal dose of morphia. For children two years old, the minimum fatal dose of atropia is not less than for adults. There is every probability that the same is true of daturia or hyoscyamia.

It did not follow from these conclusions that the common dose of atropia or daturia should be the same as the common dose of morphia, but it was urged that in those cases in which the decided influence of a mydriatic was clearly indicated, for example, cases of iritis, these drugs should be used more freely than they often are. In the meanwhile, the proper measures might be taken to avoid the unpleasant symptoms of mydriatic intoxication; and even if this should to some extent

occur, it was not to be regarded as more indicative of danger than the intoxication produced by alcohol or ether.

Dr. Albert G. Heyl, of Philadelphia, then read a paper on a form of

EPITHELIAL MYCOSIS.

This disease has been known under various names, *e.g.*, corneal gangrene, kerato-malacia, etc. Graefe described it under the title of corneal ulcer of infantile encephalitis; his idea being that the corneal affection was of a trophic nature, the primary cause being an encephalitis. Jastrawitz has made this hypothesis untenable by showing that these supposed encephalitic products are simply the remnants of fœtal life. Leben within a few months has given a full description of a parasite found *intra nitam* in the conjunctival débris and *post-mortem* in the epithelium of the renal pelvis and in the small intestine. This parasite attacks the epithelial cell, inducing fatty degeneration of its structure. The dead cells accumulate in lamina, giving rise to a characteristic, dry, parchment-like appearance the so-called conjunctival xerosis. The disease is usually ushered in by hemeralopia. This symptom, which is associated with the conjunctival xerosis, may last a month or two, when corneal ulceration commences. About this time general symptoms appear. There are rise in body temperature, frequency of pulse, a dry, harsh condition of skin, and the hair on the head becomes dry, lustreless. Along with this a peculiar state of apathy is developed. Persistent purging and vomiting occur, and finally broncho-pneumonia, to which the patient succumbs.

All cases do not run precisely this course. Some do not proceed beyond the stage of hemeralopia; in others the corneal ulceration appears after the inception of the general symptoms. In some the apathetic state is the most striking symptom. In some constipation exists, instead of the purging. The existence of a parasite in the conjunctiva in this disease was known before Leben's researches. But Leben has not only given a clear account of it, but has also shown that it attacks the epithelial cell, and that it is found in other localities beside that of the conjunctiva. Probably the symptoms of the disease are traceable to this epithelial mycosis. Reasons were adduced for considering the epithelial cells as the receptive organ of centripetal nerves. Destroy these receptive organs in the conjunctiva, and certain impressions of light will fail of being conveyed to the proper centre. A distinction was drawn between those impressions which, coming from the outer world, may issue into voluntary action, and those which issue into involuntary action. Thus the sensation of light and that impression of light which is followed by the reflex closure of the lids are two different things. It is the latter which is absent in this disease by reason of the destruction of the terminal epithelial cells by which it is accomplished. The same rationale may be applied to the skin, which is a vital organ, containing a principal part of the thermic apparatus. The epithelial cells may be looked upon as the receptive organs through which the sweat glands are set in action. Destroy these and the function will be abrogated. Hence the apathetic state and possibly the broncho-pneumonia are developed. The purging and vomiting seem to be due to the direct presence of the parasite. In the treatment the careful administration of food is important, and as the application of moist heat to the eye has been found very serviceable, possibly it would also be if applied to the surface of the skin.

Dr. Carl Seiler, of Philadelphia, then described

A NEW ELECTRIC LARYNGOSCOPE,

which consists of the ordinary head-reflector mounted on a head-band by means of a ball-and-socket joint. From the lower rim of the mirror extends a slotted arm about four inches in length, upon the end of which is mounted a small incandescent lamp. Between the lamp and the reflector is a simple biconvex lens for the purpose of concentrating the light of the lamp upon the head-mirror, thus shortening the focus. To prevent the light from falling directly upon the patient's face, the anterior portion of the lamp is surrounded by a shield of silvered mica, which acts as a reflector. The wires from the battery run from the lamp along the bar and are fastened to the head-band, so that they hang from the back of the head of the operator. Any battery which has sufficient electromotive force to overcome the resistance of the carbon filament of the lamp may be used. The advantages of this instrument in illuminating the laryngeal and other cavities of the body are, that the light being once adjusted always is reflected in the direction of the axes of the eyes; that it is light, gives off very little heat and a whiter light than gas or a coal-oil lamp. And, finally, it can be used as an ordinary head-mirror without the electric lamp should the source of electricity give out, an accident which not infrequently happens, especially when the operator is not perfectly familiar with the tricks and vagaries of batteries. The paper was illustrated by the exhibition of the instrument, which gave forth a very satisfactory light.

Dr. Charles S. Turnbull, of Philadelphia, in a paper entitled

DOES A CHRONIC DISCHARGE FROM THE EAR MAKE LIFE INSURANCE HAZARDOUS,

called attention to the importance of chronic ear disease as a source of danger to life. Deafness of a dangerous or hazardous degree cannot be concealed, and is only an element of risk in so far as accident is concerned, while a chronic purulent inflammation of the middle ear, with perhaps some polypoid or necrotic complications, can be, and often is unwittingly concealed or overlooked, while it threatens life within a year. One remaining sound ear may do all the work, and the examiners may never suspect the defect.

Dr. Peter D. Keyser then presented *Some Ophthalmological Observations during Ten Years' Service in Wills Eye Hospital.*

Dr. E. T. Bruen, of Philadelphia, then read a paper jointly by himself and Dr. J. William White on

THE OPERATIVE TREATMENT OF PURULENT PLEURAL EFFUSIONS,

based on thirteen cases of empyema treated since 1877.

In serous effusion, whether undisturbed or treated by paracentesis, the predisposing causes of empyema were considered to be lowered vitality, scrofulous constitution and intercurrent disease. The termination of empyema, and the effects of pleural effusion upon the

lungs, were next dealt with. In regard to the diagnosis, the crucial test is by puncture.

Indications for treatment were then considered. Allusion was made to the healing process through the medium of adhesions of the inflamed pleural surfaces. Every movement of the chest walls draws the surface of the lung with it. When the fluid is evacuated or absorbed the character of the respiratory movements is improved, and they diminish in frequency as well as shallowness. The lung, being adherent, is dragged by the ribs in all their increasing movements. The lung expands, the adhesions to the chest wall increase; each fresh expansion results in further adhesions to the costal surface, which then acquires more power over the lung to promote its return to the normal state. The air in the pleural cavity does not interfere with healing. The point of puncture is the seventh intercostal space, and in a line with the posterior border of the axilla on the right, and on the left side the eighth space on the same line. The seventh rib is the last attached to the sternum, and can be easily traced.

The method of introducing a drainage-tube and dressings was noticed, as also the plan adopted in the resection of the ribs. A case in which the writers had performed this operation was reported, and the portion of the ribs shown.

The following conclusions were formulated:

1. The formation of purulent effusions is dependent on lowered vitality, scrofulous diathesis, and intercurrent disease.

2. The diagnosis can only be made certainly by puncture and inspection of the fluid. This method of examination need not be delayed for fear of favoring the purulent transformation of a serous fluid if proper aseptic precautions are observed.

3. In young children one or two aspirations will often suffice for a cure. If these fail, incision of the chest without the introduction of a drainage-tube is often all that is requisite.

4. In older children and in adults it is proper to aspirate once, but recovery not resulting promptly, a large drainage-tube should be inserted at the most dependent point.

5. If, after this, drainage is still imperfect, as shown by the fetid character of the discharge, a second opening should be made, and a tube carried directly across the base of the cavity.

6. If after a suitable delay, from two to four months, there is no disposition to permanent closure of the suppurating cavity, but if the lung has expanded sufficiently to indicate that it is capable of further descent it would then be proper to facilitate its expansion, and the obliteration of the cavity by removing certain portions of the ribs of the affected side.

7. If thorough drainage is accomplished, the use of disinfectants by intrathoracic injections is rendered unnecessary unless a stimulant to the granulating surface is required.

8. In cases in which the lung is at the bottom of the chest and bound fast to the diaphragm, in which it has been so atrophied prior to aspiration that there is no possibility of re-inflation, or in which it is occupied by a tuberculous or an inflammatory infiltration, this operation is contraindicated.

THE ADDRESS IN SURGERY

was then delivered by DR. JOHN B. ROBERTS, who took for his subject *Surgical Delusions*.

Many surgical theories and procedures have become traditional, and are accepted as true and correct, merely because reverence for antiquity or careless acceptance has not questioned their right to be classed as surgical facts. The present age is an incredulous one, and demands accurate investigation of all such claims. The field of investigation is large, for progress has been retarded by the influence of theorizing writers with monochromatic vision, the example of non-seeing and non-looking devotees of the fetiches of surgical superstition, and the convincing effect of a repetition of false statements. The author selected a few topics which have greatly interested him, and concerning which he probably differed quite widely from many.

Adherence to chloroform in the face of well-known facts as to its danger is criminal when circumstances permit ether to be obtained. The assertion that it is often impossible to produce anæsthesia with ether is the result of inefficient methods of administration. Ether, if given as chloroform is and should be given, is a useless anæsthetic; but, given properly, it is efficient.

Value of Styptics.—The belief in the necessity of styptics is a delusion less dangerous, but is given more extended credence. Such agents are seldom, probably never, needed in general surgery to arrest hemorrhage. When ligatures, torsion, or acupressure is not demanded (and such is seldom the case unless the artery is as large as the facial), moderate direct pressure applied in dressing the wound is the only hemostatic required. Styptics often do harm; and, as they are not needed, they should be discarded.

Danger of Trephining the Skull.—The dislike to make exploratory incisions in closed fractures of the skull evinced by some surgeons, and the objection of others to trephining and thus opening the diplöic structure in open fractures, are delusions of a most disastrous tendency. To wait until symptoms of cerebral compression or inflammation have supervened is to lose the most favorable opportunity for mechanical relief. Such a Fabian policy is often followed by death. The treatment of open and of closed fractures of the skull should not be looked upon as very different, since, with the present improved methods of dressing wounds, the successful issue depends almost entirely upon the cerebral rather than the cranial phase of the injury. If such fractures as are usually seen in the skull were not in proximity to the brain, the surgeon would consider them almost trivial. The feature of closed fractures that renders them so troublesome is the obscurity that accompanies them. The author has for a number of years strongly advocated making closed fractures open ones by means of an exploratory incision whenever there is a suspicion of the existence of depression or splintering. In open fractures, operations to elevate depressed portions, and to get rid of splinters of the inner table thrust into the membranes, should be undertaken. It is better to err on the side of action than that of inaction. Careful manipulation and proper dressings at an early stage are sources of less risk than is incurred by the surgeon who leaves unseen and unsuspected fragments thrust into the membranes or brain.

Operative Delay in Strangulated Hernia.—A similar delusion of fatal issue is that leading to postponement of operative interference in strangulated hernia. Repeated attempts at forcible taxis and medical powwowing with temporizing measures, have ended more lives than the use of the knife. Herniotomy, done within twelve hours, is almost always followed by recovery. Death is to be expected, however, if strangulation has existed for two or three days; and the gut has been bruised by violent manipulation in the endeavor to relieve the constriction by taxis. Moderate taxis under ether, a half day's treatment with cold applications and the internal use of morphia, and a second moderate attempt at taxis, followed, if unsuccessful, by immediate operation, is the sequence to be followed in strangulated hernia. When symptoms of strangulated hernia exist, the slightest fulness and tenderness in one groin over either of the rings, is a sufficient localizing indication to warrant operation.

Operative Delay in Acute Phlegmonous Inflammation.—No insane delusion, no Spanish Inquisitor, ever caused so many hours of excruciating physical torture as the hallucination that acute abscesses and furuncles must not be incised until pointing has occurred. All the world knows that evacuation of imprisoned pus in phlegmonous inflammations means instant relief of the agonizing pain; yet how few of the profession early and freely incise such inflamed tissues unless they first see the yellow pus under the thinned skin or feel the fluctuation of the fluid in the abscess cavity. The pain is caused by the effort of the pus and the sloughing tissue to escape. Is it not, then, more rational to make a free incision to-day than to wait till next week? Time and pain are both saved by early incision. If the cut is made before the pus is formed, so much the better. Probably no form of abscess needs early and free incision more imperatively than that under the palmar fascia. Destructive burrowing of pus is prevented by this radical procedure; which also saves the patient many days of poultices and purgatory.

Operative Delay in Malignant Tumors.—Much bad surgery results from a delusive postponement of operative interference in malignant diseases. Instant removal is to be practised in such cases, provided the patient is deemed fit to stand the surgical shock.

Necessary Fatality of Traumatic Tetanus.—That traumatic tetanus is, of necessity, fatal, is a commonly held opinion. Proper treatment is sometimes neglected because of this belief in its hopelessness. That the prognosis is extremely unfavorable was admitted, but that cases of a severe type recover is undoubted. Chloral hydrate in full doses has given the best results; but he merely wished to impress the fact that a fair number of cases of traumatic tetanus recover.

Fatality of Pericardial and Cardiac Wounds.—The prevalent notion of the excessive danger of these wounds is delusional; at least in as far as it teaches that these structures will not brook surgical interference. The pericardial sac should be dealt with exactly as the pleural sac by aspiration, incision, irrigation, and drainage, according to the lesion. That simple puncture or aspiration of the heart itself is not accompanied by the expected risk to life has been pretty well shown, though I am not prepared to recommend its general adoption for trivial cardiac conditions.

Symmetry of Normal Limbs.—Another delusion still existing in many minds is that the lower extremities are usually of the same length. Clinical and anatomical investigations show that asymmetry in the length of normal limbs is of common occurrence? Therefore measurements of the legs in cases of fracture are of little value, since it is impossible to know whether a long or a short leg is the seat of injury.

There are many other prevalent surgical delusions such as: That bony union of transverse fractures of the patella and of intracapsular fractures of the femoral neck cannot take place; that chronic purulent discharges from the ear do not need active treatment; that hypermetropia and hypermetropic astigmatism can be properly estimated and corrected without paralyzing the accommodation; that it is improper to perforate the nasal septum in cases of great deviation; that crooked noses are not amenable to treatment; that corneal operations and cataract extractions should be treated by cotton padding and bandages to the eyes; that fractures should be treated with carved or manufactured splints.

While an earnest advocate of conservative and of reparative surgery, Dr. Roberts believes that when operative surgery is demanded it should be aggressive. Delay, indecision, and inefficiency, impair the value of much surgical work and are often the legitimate result of a superstitious faith in delusive surgical dogmas.

DR. C. B. NANCREDE, of Philadelphia, then read a paper on

BICHLORIDE OF MERCURY AS A SURGICAL DRESSING.

He entered into some general remarks on the value of antiseptics in surgery and quoted statistics to support his statement. He regarded the corrosive chloride as superior to carbolic acid. The constitutional effect of mercury was sometimes observed, and sometimes it reddened the skin. It was not advisable to use the bichloride for instruments, as it rusted them. The dressing, when the bichloride was used, might, if thought advisable, be left on for as long as eight days without once being removed.

The mode of using the bichloride is as follows: The parts are thoroughly cleansed with soap and water, and are then bathed with turpentine and alcohol, 1 to 7. Sponges are put into a solution of bichloride of 1 to 2000; the instruments into a 1 to 40 solution of carbolic acid. The operation completed, vessels are ligated, a drainage-tube is inserted, and the wound washed with the solution of the bichloride, 1 to 2000. The opposing surfaces are brought together, and a dressing which has been soaked in the solution of the bichloride is applied and kept in place by gauze bandages which have also been saturated with the solution. Outside of this dressing other antiseptic pads are placed when necessary. At times the outer layers become discolored with discharges which emit a gluey odor, but on removing these the inner layers are found to be perfectly sweet. The bichloride solution 1 to 4000 or 1 to 2000 is as strong as there is ever any need for using.

THE JUDICIAL COUNCIL

reported that in the case of appeal of Dr. Cotton from the decision of the Censors of the Tenth District, both parties were heard and the papers submitted considered. It was decided that the notice of the special meeting to

convene at Townsville, November 6, 1880, was not adequate, in that it failed to state by what authority or for what purpose it was called. It was decided that the published *Transactions* of the State Society must be accepted as authentic in all its appointments. The following motion was adopted: *Resolved*, That the case be recommitted to the Censors of the Tenth District, with instructions that they return it to the Crawford County Medical Society for their early action.

DR. TURNBULL, of Philadelphia, presented a series of resolutions endorsing the action of the Alumni Association of the Jefferson Medical College in regard to the erection in Fairmount Park of a

STATUE OF PROF. S. D. GROSS,

and providing for a committee of five to be appointed to act in connection with said Alumni Association. Carried.

THE COMMITTEE ON PUBLICATION

presented a report recommending the passage of the following resolutions:

Resolved, That all papers read or appointed to be read before this Society, become thereby the exclusive property of the Society, and the author has no right to publish or cause to be published the paper or any part of the same without the consent of the Society, and that the Committee on Publication shall not be at liberty to publish any paper that has been published in violation of the above requirements.

Resolved, That the Medical Society of the State of Pennsylvania looks with great disfavor upon the making use of its meeting as an advertising medium, and holds such practice as contemptible, and a flagrant violation of the spirit of the Code of Medical Ethics.

The report, after some discussion, was laid on the table for further consideration.

The Chair announced the appointment of the

COMMITTEE ON LICENSE TO PRACTISE,

as follows; Drs. E. Jackson, of Chester; Traill Green, of Northampton; William Varian, of Crawford; J. M. Deaver, of Philadelphia; H. Leffmann, of Philadelphia; ——— Gates, of Luzerne, and F. Woodbury, of Philadelphia.

AFTERNOON SESSION.

DR. DE FOREST WILLARD, of Philadelphia, read a paper on

THE NON-NECESSITY OF TARSOTOMY IN TALIPES OF CHILDREN.

He reported the case of a girl, aged eight, who had double congenital varo-equinus of extreme degree, and who was tenotomized in infancy but totally neglected, and walked barefooted until eight. When first seen her toes looked backwards, soles outwards; rotation of tibiæ thirty degrees on long axis upon femur, and heels presenting outwards; abrupt angle at medio-tarsal articulation. She walked upon large bursal cushions and callosities on the outer dorsal aspect of feet, as seen in Fig. 1.

The tissues were dense and contracted, and pressure rectified the deformity but slightly. Powerful manual pressure, *redressement forcé*, was employed after tenotomy of both tibials and the long flexor, and of all tissues down to the bones upon the inside of the foot, and then section of tendo Achillis. After much stretching the feet were brought straight, and secured by gypsum splints. A powerful assistant, by accident, ruptured the internal lateral or deltoid ligament, and the superimposed tissues

FIG. 1.

Front view, from photograph.

giving way on the third day, the ankle-joint was opened, but drainage and carbolized oil-dressings closed the wound in six weeks. Her condition two years later is as seen in Fig. 2. She walks upon the soles; the right foot is

FIG. 2.

almost straight, but more rigid than the left, owing to the lacerations reported above; deviation in mediotarsal joint in left foot only slight, but the knee rotation still remains, and although spiral-spring eversion from pelvis as a base has been thoroughly tried, yet but little has been accomplished and no operative procedure promises success. This tibial twist serves constantly to throw the foot inward in walking, but can be counteracted by the patient whenever her attention is fixed.

It may have been congenital in its origin, or have been produced by the effort to prevent contact of toes during the years of reel-foot walking. She now walks

without a cane, and can dispense with apparatus on right foot. The left is retained in position by the author's shoe, Fig. 3, which acts by elastic tension ex-

FIG. 3.

erted by webbing attached at *c*, upward and outward upon *b*, through the medium of catgut cord playing through the eyelet *a*, a flexible joint in the sole being secured by soft leather in the shank.

Davy with his twenty-two operations reported up to June, 1882, is the only single operator, who has had a sufficient personal experience to speak with authority upon tarsotomy, but his one death from septicæmia gives a mortality of four and a half per cent., which is a very unfavorable showing as compared with the safety of tenotomy in the thousands of cases in which it has been performed. In 58 tarsotomies in 50 patients, 3 have died, showing that it is an operation that should still be looked upon as a *dernier ressort*, although Davy, Rupprecht, and König would not give it such a limited sphere, the former having performed one-half of his operations upon children under eleven. One certainly cannot believe that in an infant of sixteen months the bones could have become wedge-shaped, and if not so, the force necessary to restore the foot after tenotomy would not have been severe. Guérin says that the case of club-foot, however complicated, does not exist which is not curable without tarsotomy. Looking at the operation from the standpoint of subsequent walking powers, moreover, we find that a resected tarsus must necessarily be stiff from ankylosis; that caries or synovitis may result; that apparatus is frequently a necessity for locomotion; and that subsequent operations have been required in a number of cases.

The author then gave a *résumé* of 80 cases of tarsotomy upon 68 patients, 58 of which were wedge-shaped sections; 13 were resections of the astragalus, and 9 were excisions of the cuboid. His conclusions were:

1. In children under ten, even in extreme cases, subcutaneous division of all the contracted tissues, with powerful manual force applied even to a degree which would seem severe to one who has not tested it, will restore the feet to a proper position. Even laceration of plantar ligaments, or fracture if necessary, would still be subcutaneous and less dangerous than the opening of cancellous tissue.

2. Fixation by gypsum immediately after restoration, needs to be continued but a short time, after which stretching and the use of an apparatus that encourages muscular action, will give a more movable and a better walking foot than will be gained by tarsotomy.

3. Cases are not necessarily incurable because tenotomy has already failed. Since strict hospital supervision may be able to attain a good result, a careless parent can easily defeat the best efforts of the surgeon.

4. Tarsotomy, by reason of its risk and the rigid feet which it produces, should be limited to cases in which moderate measures have failed, and to adults with deformed tarsal bones. In these cases the operation becomes one of great value. It should be performed absolutely antiseptically, the wedge-shaped section with the saw being much more certain in its results than excision of the cuboid or of the astralagus.

DR. A. SYDNEY ROBERTS, of Philadelphia, then read a paper on

CHRONIC ARTICULAR OSTEITIS OF THE KNEE-JOINT.

He used the term to describe the condition known as tumor albus. His reason for so doing was by proper classification to refer directly to the inflammation of the cancellous structure of bone, thus avoiding confusion from the more general terms of arthritis or knee-joint disease.

From an analysis of many hundred cases he felt safe in asserting that only two structures are responsible: 1. The cancellous structure of the epiphyses. 2. The synovial membrane. These two are combined as a rule; one may develop from the other. The term arthritis is not justifiable till the cartilage and ligaments are invaded.

The author then described at length the pathology of the subject. Rigidity was due to inflammation, to the irritation of the nerves distributed through the epiphyses. The treatment of these conditions is among the most difficult problems that may fall to the lot of a general surgeon. To meet the universally recognized principles of treatment, *i. e.*, fixation of the joint in extension, I have designed a splint that I now feel justified, from its successes, in presenting to the profession.. It consists of two light steel, padded troughs, that are firmly secured to the limb by encircling bands of surgical webbing, affording absolute fixation to the joint when the extending rods are locked after adjustment. Three ratchet extension bars, arranged in the form of a triangle, are placed posteriorly corresponding to the long axis of the limb, placing within the control of the surgeon a power that will overcome the flexion and the tendency to the production of deformity, and at the same time produce extension. It will be noticed that the extension rod acts directly on the head of the tibia, and parallel with the line of contraction of the flexor group of muscles, obviously avoiding thereby the error in the mechanical arrangement of the popular Stromeyer's splint, or in all where the power is applied low down on the tibia to overcome flexion. In the splint under consideration, the long extension rod is used only as a compensating bar, adjusting the angle of the splint to the angle of the flexion of the limb. The power for restoring the head of the tibia and overcoming the spasmodic contraction of the flexor muscles, is applied directly in the axis of their contraction. Through the extension bar the head of the bone describes in its restoration the arc of a circle. The compensating bar in

correcting the angle of flexion, carries the limb through an arc whose centre is in the end of the femur. Mechanically, this arrangement of force corrects the deformity and relieves, by extension, the reflex spasm of the flexor muscles without crowding together the diseased joint surfaces or aiding in subluxating the head of the tibia, as would be the case should the limb proper be used as the long arm of our lever, with the insertion of the hamstring tendons instead of the normal centre of motion of the joint as the centre of motion of the splint.

Supplementing the direct extension upon the contracted muscles, another bar has been added to aid in steadying the joint and relieving interarticular pressure. Its action upon the limb is produced through adhesive plaster applied above and below the joint, to which surgical webbing has been attached. This is firmly secured to a counter-extending band and to the extension rod, affording a means of direct extension always corresponding to the angle of flexions. The extension bars are controlled by a key and ratchet movement, held in place after adjustment by a small ring and pin. I have found that this method of securing fixation with extension by a portable appliance, enables the patient to enjoy, by means of crutches, all the hygienic advantages of open air and exercise, facilitating thereby a better result than would be otherwise obtained.

DR. W. S. JANNEY, of Philadelphia, then presented a case of *Unusual Displacement of the Trachea by a Tumor, with Tracheotomy Tube Inserted Two Inches to the Left of the Median Line of the Neck.*

On motion, the report of the Special Committee on the

PUBLICATION OF PAPERS

was taken from the table.

DR. STRAWBRIDGE offered the following amendment as an addition to the first resolution: And that the Chairman of the Committee on Publication be authorized to publish an abstract of papers read before this Society, said publications not to interfere with the authorized yearly publications.

An additional amendment, to the effect that members shall furnish abstracts of their papers for publication to the Chairman of the Committee on Publication was offered, and on vote was declared lost.

The first amendment was then adopted, and the original resolution as amended was then passed.

MEDICAL ADVERTISING.

The following resolution was then unanimously adopted:

Resolved, That the Medical Society of the State of Pennsylvania looks with great disfavor upon the making use of its meeting as an advertising medium, and holds such practice as contemptible, and a flagrant violation of the spirit of the Code of Medical Ethics.

THE REPORT OF THE COMMITTEE TO SECURE A STATE BOARD OF HEALTH

was then presented. It stated that the bill to establish a State Board had failed in the last legislature by a single vote, but that in another year the Committee hoped to present a more favorable report.

CHANGE OF DATE OF MEETING.

DR. A. M. POLLOCK, of Alleghany, moved that when we adjourn we adjourn to meet at Scranton on the last Wednesday in May, 1885, and not the second Wednesday, as previously agreed upon. Adopted.

MISCELLANEOUS BUSINESS.

The Committee on the appeal of the American Anti-Vivisection Society was then authorized to publish its report in full and to circulate it at its discretion.

The Permanent Secretary was authorized to employ such clerical assistants as may be necessary in making abstracts.

THE APPOINTMENT OF THE ADDRESSES FOR 1885

were announced, as follows:

Surgery.—Dr. E. A. Wood, of Alleghany.
Obstetrics.—Dr. C. A. Rahter, of Dauphin.
Hygiene.—Dr. Joseph G. Richardson, of Philadelphia.
Mental Diseases.—Dr. S. S. Schultz, of Montour.
Medicine.—Dr. E. T. Bruen, of Philadelphia.
Otology.—Dr. C. S. Turnbull, of Philadelphia.

A GROSS MEMORIAL

page was ordered to be inserted in the *Transactions.*

Adjourned.

SOUTH CAROLINA MEDICAL ASSOCIATION.

Thirty-fourth Annual Meeting, held at Florence, April 22, 23, and 24, 1884.

(Specially reported for THE MEDICAL NEWS.)

THE thirty-fourth annual session of the South Carolina Medical Association was held in the hall of the Knights of Honor, Florence, April 22, 23, and 24, 1884, THE PRESIDENT, R. A. KINLOCH, M.D., in the chair. The attendance was fair, and eighteen new members were added to the roll.

THE PRESIDENT, DR. R. A. KINLOCH, delivered

THE ANNUAL ADDRESS,

the subject being *A Plea for Education as the Means for Unifying the Profession and Strengthening the Association.* After congratulating the Association upon the celebration of its thirty-fourth anniversary, and acknowledging the kind feeling and generous hospitality of the local profession, on this the first occasion of a meeting in this section, Dr. Kinloch went on to say that, in his choice of a subject, he was guided by the idea of duty to address the Association in words of admonition and advice regarding what he considered its greatest need.

The highest aim of the Association should be to secure professional advancement, professional and social unity and harmony.

A retrospect of the past thirty-five years brings to a true lover of the profession in the State a feeling of sadness and infinite disappointment. In the address of the first President of the Association, Dr. Moultrie, in 1850, it is stated that the Society then numbered two hundred and sixty members, from seventeen districts. The present roll of the Society numbers less than one hundred and fifty, a large numerical deficiency as compared with thirty-five years ago. If it could be believed that it was the purification of the profession that had thus reduced our numbers, there might be some consolation in facing the figures. But whilst it may be fairly affirmed that this body represents the intelligence, character, and working capacity of the profession in the State; it is equally well known that there are numbers

of fitting associates who are pleased to remain outside of our organization. Doubtless they have their reasons, which it might be regarded as uncharitable to criticise, but, without arguing the question, I would appeal again and again to our recreant brethren. In the name of the nobility that attaches to our art; in the name of the great and good, whose labors have guided and supported us amidst the terrors of disease and death, and whose monuments of usefulness are seen in every clime; in the name of a civilized benevolence; in the name of the majesty of scientific truth, ever struggling for sovereignty against ignorance and superstition; and in the name of the health and life of our proud State, I would exhort every member of our liberal and enlightened profession to remember his duty, and to join our ranks with every energy pledged to the development of a noble work.

Dr. Cornelius Kolloch, of Cheraw, then read an interesting report of

A CASE OF OVARIOTOMY,

in which he had operated with success, the patient having safely recovered. He also reported a case of

PERICARDITIS FOLLOWING AN ATTACK OF ACUTE RHEUMATISM,

in which he performed the operation of paracentesis of the pericardium, introducing through the fifth intercostal space a small aspirating needle near the sternum, and drawing out fully eight ounces of sero-sanguinolent fluid. The relief was instantaneous and complete. It is now more than ten months since the operation, and the patient is in perfect health.

Dr. James Evans, of Florence, read a paper on

THE SANITARY USES OF PLANTS AND FLOWERS.

Pure air, pure water, and pure soil, indispensable conditions of a fit dwelling-place for man, can be secured in a measure, he said, by a proper selection and arrangement of trees and plants around our dwellings. In spite of all care, more or less organic matter finds its way into the soil around every house and there undergoes decomposition, polluting the air and surface water. Where trees and plants grow, the soil is traversed in every direction with a network of fine fibrous roots which feed on this matter, absorbing likewise excess of moisture and draining the soil. This moisture is afterwards exhaled from the leaves, a property of plants which, it can hardly be doubted, can be used with advantage in the alleviation if not in the cure of many distressing affections, especially of the respiratory organs, by placing in the sick room a sufficient number of plants. There is no doubt that plants also exhale, with this moisture, some of their active and peculiar principles. Examples of this are found in the rhus, which produces an eczematous eruption on the skin, the Pride of India which protects from the attacks of insects, the hemlock and other plants of the same class which produce narcotic effects upon those much exposed to the atmosphere in their vicinity. The scent of mint and thyme is due to menthol and thymol, antiseptics of the highest value, and it is not improbable that their exhalations have the same property. The eucalyptus is remarkable as a prophylactic against malaria, so much so that the French Government has had groves of them planted near forts and towns in Algiers, and localities formerly subject to fearful mortality from malarial fever, are now, since the planting of these trees, comparatively exempt from its ravages. Its leaves immersed in hot water are also said to be an efficient disinfectant in the sick-room. A residence in a pine forest has long been considered beneficial to weak lungs. These active principles of plants may, when diffused through the atmosphere, be extremely diluted, but when we remember the construction of the lungs, with their extensive absorbing surface and the continuous application of the substance during every inspiration, we can readily understand their effect. And I have no doubt that when the physiological action of plants, used in this manner, is more closely studied, they will prove of the utmost value in the prevention and remedy of disease.

Plants, by virtue of their power to generate ozone and to split up carbonic acid, absorbing the carbon and setting free the oxygen, can, when grown in our chambers, remedy to some extent the evils of bad ventilation. In Pasteur's virus-culture experiments he found that, when they were conducted under a diminished supply of oxygen, the germs retained their primitive virulence, but, on the contrary, when they had access to oxygen the virus became weaker. Now it has been known, for a long time, that marsh miasm is intercepted by a forest, and that persons living in localities so screened are exempt from attacks of malarial fever. The explanation of this is probably to be found in this discovery of Pasteur. When a cloud of malarial germs are wafted from a marsh to the neighboring forest, they encounter a continuous stream of oxygen pouring forth from every leaf, attenuating the virus and rendering it innocuous.

Dr. O. B. Mayer, Jr., of Newberry, read a paper on

PELVIC PERITONITIS AND CELLULITIS,

in which he said that both before puberty and after the menopause this disease is rare. It frequently occurs after abortion, especially if it be criminal. Its most common causes are the extension of inflammation from the uterus, absorption of septic matter from the genital tract, and exposure during or immediately after menstruation. One cause, which seems to have been overlooked by gynecological writers, is the extension of inflammation from the corpus luteum in those cases in which there is sufficient vaso-motor disturbance to produce a hyperæmic condition.

Dr. John M. Thompson, of Newberry, reported

A CASE OF SEPTICÆMIA FROM THE BITE OF A RAT.

The patient, a man twenty-five years of age, lived in an old wooden house, its foundations decayed and its walls infested with rats and filled with their accumulations of filth. Swamps surrounded the locality, and the patient had long suffered from chills and fever. On the 15th of last September, while he was trying to kill a rat, he was bitten through the palmar surface of the ring finger of the left hand, near the end. The wound gave him only momentary pain, and in a few days it had healed and was forgotten. But about ten days later the finger began to throb and give him great pain. Dr. Thompson saw him on the following morning; his finger was swollen, inflamed, and exceedingly painful, and he had some fever. Quinine and iron were given in full doses, poultices were applied, and morphia administered. In spite

of treatment, the inflammation increased, and the tension was so great that an incision was made through the entire length of the palmar surface of the last phalanx, which was followed by a discharge of bloody serum. Charcoal poultices were substituted for flaxseed, the iron was left off, and stimulants added. There was no improvement, and on October 2d the end of the finger was found to be cold, and it was evident that mortification had begun. He suggested amputation, but the patient steadily refused until October 4th, after he had called in consultation Dr. O. B. Mayer, Jr., who advised immediate amputation, and the operation was performed, with antiseptic precautions, by Dr. Mayer, by disarticulating the finger at the metacarpo-phalangeal articulation, avoiding the removal of the end of the metacarpus for fear of septic absorption. No immediate improvement followed the operation, but, on the contrary, he appeared to grow worse, and two weeks after his condition was extremely critical. The wound had healed but little, the pulse was 125 to 130, the temperature 103° to 104½°. Red spots, half an inch in diameter, which first appeared on the wrist and forearm the day of the operation, soon covered the whole body. The treatment now consisted of nitro-muriatic acid, the hypophosphites of lime and soda, and quinine. Opium was substituted for morphia with a happy effect. The diet was highly nutritious, and brandy was given freely. The wound was dressed twice daily with carbolized glycerine. He remained in this critical condition a week or ten days before any change for the better took place. Then he began to improve slowly; the fever abating, the wound began to heal, the spots to disappear, and his strength to return. During convalescence chills occurred which proved very obstinate. It was two months from the day he was bitten before he was able to walk about again.

DR. H. MCMILLAN presented a report of a case of

SEVERE ABDOMINAL WOUND, WITH RECOVERY.

On August 8, 1883, he was called to see a colored man, an engineer, who had received a wound. He found the patient in the road, where he had lain for four hours, with his bowels protruding through a severe abdominal wound, and lying on the ground covered with dirt. On examination he found an incised wound about four and a half inches in length, running obliquely across the umbilical region, and the small intestine cut half through transversely in one place, where the fecal matter had poured out freely. After removal to a house near by, chloroform was administered, the intestines were thoroughly cleansed with tepid water, and the serous surfaces of the wound were inverted and sewed up with the continued silk suture, both needle and thread being very fine. At this stage the patient vomited once and became collapsed, but ether having been administered hypodermatically, he rallied. The protruded viscera were then restored to the abdominal cavity, the abdominal wound closed, and a broad bandage passed around the abdomen. A hypodermatic injection of morphia and atropia was administered. No nourishment was taken for thirty-six hours, after which iced milk formed the diet. The bowels were controlled with opium, until August 13th, when they were evacuated by an enema. On August 17th an abdominal supporter was applied, and the patient was discharged. No antiseptics were used in the case, and no solid food was taken for ten days after the accident. The patient is now in perfect health.

After the reading of a number of other papers, the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. A. A. Moore, of Camden.

Vice-Presidents.—Drs. C. Kolloch, of Cheraw; James Evans, of Florence; and T. J. McKie, of Woodlawn.

Recording Secretary.—Dr. John Forrest, of Charleston,

Corresponding Secretary.—Dr. H. D. Fraser, of Charleston.

Treasurer.—Dr. H.W. De Saussure, Jr., of Charleston.

The Association then adjourned to meet at Charleston, an April 23, 1885.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, April 21, 1884.

THE PRESIDENT, WILLIAM DETMOLD, M.D., IN THE CHAIR.

DR. CHARLES A. LEALE read a paper entitled

SCARLATINA OF THE FŒTUS IN UTERO, AND OF THE MOTHER AT THE NINTH MONTH OF UTERO-GESTATION.

(See page 635.)

THE PRESIDENT, in opening the discussion, remarked that it was not surprising to him that the parturient woman should be in great danger from scarlatina, since the peculiar condition of the kidneys, approaching as it often did to genuine Bright's disease, offered a sufficient explanation, he thought, of the great fatality of the disease in such patients.

DR. DWYER said that he had seen one case of scarlatina in the parturient woman, in which the mother suffered from violent eclampsia and expired at the moment of the birth of the child. The child was affected with undoubted scarlatina when born, two eminent physicians who were in attendance concurring in the diagnosis. He had, however, met with three cases in which pregnant women nursed children having scarlet fever, who escaped the disease themselves and whose infants, when born, did not have it.

DR. GOULEY thought that the peculiar form of nephritis incident to scarlatina must make the subject of the liability of parturient women to the disease of immense interest to obstetricians, since the whole abdominal circulation of such patients was impeded, while the kidneys were often intensely congested, and the renal tubes so filled with blood as to give rise to hæmaturia. If patients in this condition were fortunate enough to recover from scarlatina, it seemed to him that there was imminent danger of their being affected with permanent nephritis.

DR. LUSK said that he would only make a few remarks, which might, perhaps, serve to bring into stronger relief some of the points brought out in the paper. It was a matter of great interest, he thought, that a pregnant woman, when exposed to the infection of scarlatina, rarely developed the eruption and other signs of the disease until the occurrence of labor, or even after the birth of the child. Either the period of incubation was very long, or the poison remained dormant in the system until the time of parturition. Again, there was often an irregularity about the symptoms of scarlatina in par-

turient women; the eruption and fever, for instance, occurring simultaneously. In quite a large proportion of cases, too, there were no throat symptoms, and the patients often died before any symptoms referable to the kidneys had become developed. As to the possibility of the occurrence of a scarlatinous rash due to puerperal septicæmia, and entirely independent of the infection of true scarlatina, he had his doubts; and certainly he himself had never seen this phenomenon except in connection with the real scarlatina poison. Scarlatina in the parturient woman, as a rule, he believed, was not associated with inflammation of the peritoneum or with pelvic cellulitis. While the disease was undoubtedly to be guarded against as peculiarly dangerous at the puerperal period, it was not to be altogether lost sight of that, when it occurred among children, the result depended to a great extent on the general character of the epidemic prevailing, as well as the special circumstances connected with each individual case. Even among parturient women, then, experience had proved that in some cases the disease was very light.

Dr. Lusk then alluded to the researches of Braxton Hicks, who had maintained that the indistinct rash attributed to supposed pyæmia in puerperal women might in some cases be a scarlet fever introduced unsuspectedly from without, and that other cases of puerperal septicæmia, in which there was no rash or any of the ordinary signs of scarlatina, were in reality due to this disease. The exanthemata, he claimed, sometimes occurred without rash, the intensity of the poison in some instances causing death during the period of the incubation of the rash; so that there might be certain conditions of the human body which did not permit the ordinary manifestations of these diseases, and the sore throat and skin rash could not, therefore, be regarded as the essential characteristics of scarlet fever. For instance, the poison producing erysipelas could act fatally upon the puerperal woman without any external skin affection; and it was certainly a significant fact that puerperal disturbances were always associated with epidemics of scarlet fever. Out of 68 cases of puerperal disease seen in consultation by Braxton Hicks, no less than 37 were distinctly traced to the scarlatinal poison. Of these, 20 had the characteristic rash of the disease; but the remaining 17, although the history clearly proved exposure to the contagion of scarlet fever, as he believed, showed none of its usual signs, and were not to be distinguished from ordinary typical cases of the so-called puerperal fever.

In England, Dr. Lusk continued, the statistics showed that the child has taken scarlatina from a mother suffering from such an attack of puerperal fever; but, so far as he was aware, no instance of this kind had ever been reported in this country. The records of the New York Health Department, for nine years, showed no proportion between the relative frequency of deaths from puerperal fever and deaths from scarlatina; and Matthews Duncan had found the same thing true in the mortuary statistics of London. At the same time, he was not sure that Braxton Hicks might not be right in his views after all. If a physician should go to a case of confinement from one of scarlatina, and the case should turn out badly, he would be pretty sure to blame himself, whatever the patient died of; and, therefore, he thought that obstetricians could not be too careful in guarding against all possible chances of infection. Those who were sceptical, were likely to be very severely punished. Thus, there were one or two cases in the past, in regard to which he could not but reproach himself for not having taken as ample precautions as he might perhaps have done.

DR. S. T. HUBBARD said that in the only case of scarlet fever occurring in a parturient woman which he had met with in his practice, the attack came on upon the third day after labor. The eruption was well marked, and the patient died on the third day after its commencement. The child died on the fifth day from its birth. He could not trace the origin of the attack. He thought it was the duty of the physician to refuse to attend any lying-in women at the same time that he was in charge of a case of scarlet fever, and this precaution he had always observed in his own practice.

DR. C. S. WOOD was inclined to think that the danger of puerperal women from contagion had been somewhat exaggerated. In epidemics of scarlatina, he had always watched parturient patients who had never had the disease with much anxiety, but he had arrived at the conclusion that they were not so susceptible as many supposed. In one case that he had seen, a mother nursed a child with scarlatina for twenty-one days, and ten days after the expiration of this period she was confined; but neither she nor the new-born infant had any sign of the disease, and both did perfectly well in every respect. He had now been engaged in the active practice of medicine for nearly thirty-five years, and had never seen a case of such fever in a puerperal woman which had been carried by himself.

DR. LUSK thought that it was better not to run any risks. Some time ago he had met in consultation a gentleman of this city, who had an immense practice among the poorer classes, and who had been having very unfavorable results in his obstetric cases for some time. He could not at first realize that he himself had been the primary cause of this; but at length he became fully convinced that he had been carrying infection directly from his scarlet fever patients to his parturient women.

THE PRESIDENT said that the reason why puerpural women were not infected by scarlet fever contagion more frequently than they really were, was probably because they had mostly had the disease in their childhood, and were thus, in a great measure, protected against it.

The paper was further discussed by several members, one of whom had had experience with an outbreak of scarlatina in a large tenement-house, with a house in the rear. In the two buildings there were some thirty-eight or forty families living, and nine or ten women who were expecting to be confined. One of the latter caught the disease, and was very ill with it at the time labor occurred. The child was born alive, but she herself died three days after its birth. All the other women in the house escaped, but two neighbors who came in to see this patient took the fever, which proved fatal to one of them. Another gentleman had known of a case of scarlatina to develop a week before confinement, although the patient had had the disease in childhood. After the birth of the child, which also had scarlatina, she suffered from metro-peritonitis. A third, who had

been attached to one of the large lying-in hospitals in Vienna, maintained, with many German authorities, that there was a distinct scarlatinous rash which was called forth by the puerperal state, not being produced by the contagion of scarlatina or communicable from the patient to other persons, and which could be readily diagnosticated by the symptoms present from true scarlatina.

DR. AUSTIN FLINT, SR., said that personally he had seen no case of scarlatina occurring during pregnancy or in the fœtus in utero, but he had met with one instance of the disease occurring immediately after delivery. This was one which he saw in consultation with the late Dr. J. O. Stone, of New York. The patient was twenty-eight years old, and her second child had been born two days when the eruption of scarlet fever appeared on her, although she had previously had the disease. He first saw the case four days after the appearance of the eruption, the lochia and milk having then both been checked. The urine was slightly albuminous, but within twelve days she was convalescent. Two weeks afterward, however, she was seized with an attack of rheumatism, accompanied by abundant albuminuria and a somnolent condition, and this rapidly proved fatal. No autopsy was made. The child contracted the disease from the mother, and, therefore, he thought it reasonable to suppose that the former contracted it either just before or just after delivery.

In connection with the subject of scarlatina in general, he wished to make a few remarks, and the first was in regard to—

1. *The vitality of the contagion of scarlet fever.* In 1862, he said, a case occurred in a New York boarding-house. As soon as the child was able to be moved, it was taken away, and the rooms occupied by the family were thoroughly cleansed. In three days afterward, another family moved into the same apartments, and in two days a child belonging to the latter was taken with the disease. Dr. Flint then related the case of Miss G., the daughter of a deceased New York physician, who had been well known and highly esteemed in the community. Having entered the Protestant Sisterhood of St. Barnabas, she was called upon to nurse a child suffering from scarlet fever; and after she had finished her attendance on the child, she hung up her clothing to air for several weeks. She then gave away the waist of the dress that she had worn, and put the skirt away in a trunk. It was in February, 1870, that she nursed the scarlet-fever patient, being in attendance for ten days. In January, 1871, she wore the skirt for the first time, and one week afterwards was herself attacked with acute diffused nephritis and pulmonary œdema, which proved fatal. The lesson of these cases, therefore, was the necessity for effective disinfection in all cases of scarlet fever.

2. *The frequency of acute nephritis from the scarlatinal poison.* The kidney complication was not due to cold, as was often imagined, but to the nature of the disease itself, and, hence, on account of the increased danger with which it was thus imbued, there was all the more necessity for physicians taking every possible precaution against conveying the contagion to other patients.

3. *Atypical cases are liable to occur in which there is no eruption.* In 1874, he saw a case in which there was no eruption and no sore throat, but acute desquamative nephritis occurred, and also desquamation of the skin.

4. *Heart thrombosis may prove fatal in scarlatina.* In one autopsy which he saw there was a firm clot in the right ventricle, extending into the pulmonary artery.

5. *Cold baths are of great service in reducing the temperature.* For more than fifteen years he had resorted to this measure in appropriate cases, with very satisfactory results.

6. *In the essential fevers alcohol has a marked beneficial effect.* In the light of our present knowledge, he thought it of interest to inquire whether this agent did not act in reality as a germicide in such fevers, and whether its sustaining effects were not due to this property.

DR. E. G. JANEWAY related the case of a physician in New Mexico who, after having attended a scarlet fever patient, had occasion to go to see a patient in a town twenty miles distant, in which, as he subsequently took special pains to inquire, there was absolutely no scarlet fever; yet, one week after his visit, the disease appeared in the family which he had gone to see. Similar instances of the carrying of the contagion for long distances had been reported in the *Practitioner* by physicians living in rural districts in England.

DR. LEALE said, in closing the discussion, that he believed that there was a distinction between scarlatina and septicæmia, just as the so-called scarlet rash in children, which was produced by septic poison from inflamed tonsils, was entirely distinct from true scarlatina. In the case of the family whose unfortunate experience with scarlatina he had related, the entrance of the disease was positively not due to septicæmia, because, *first*, the mother had scarlatina before the child was born; *second*, the infant was born with the disease; and, *third*, the monthly nurse also took it. As to the susceptibility of puerperal women to infection from scarlatina contagion, he did not believe this was very great. This was due, to a great extent, to the age of the patients. That the disease sometimes attacked the fœtus in utero, there was now, he believed, ample evidence, both in this country and in Europe. The point that he wished particularly to impress, was the extreme danger which the parturient woman underwent in case she should be so unfortunate as to contract scarlatina; so that, even though the chances of her doing so were small, the mere possibility of such disastrous consequences ought to be sufficient to cause us to use every precaution in preventing any exposure to the risk.

THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA.

Seventeenth Annual Session, held at Clarksburg, May 21 and 22, 1884.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, MAY 21ST—FIRST DAY.

THE Medical Society of the State of West Virginia convened at 3.30 P.M. The Chairman of the Committee of Arrangements, DR. D. PORTER MORGAN, extended to the members a warm welcome in a brief address, in which he refered to the advantages to be derived from these annual meetings.

GEN. R. S. NORTHCOTT, the Mayor of Clarksburg, then welcomed the Society to the City in an eloquent address.

Owing to the necessary absence of both the President, Dr. A. Gerstell, of Keyser, and the First Vice-President, the Chair was taken by the SECOND VICE-PRESIDENT, DR. A. F. STIFEL, of Wheeling.

The following fraternal delegates were introduced, and invited to participate in the deliberations of the Society: Drs. George H. Rohé and J. W. Chambers, of Baltimore, from the Medico-Chirurgical Faculty of Maryland; and Dr. J. W. Hoff, of Pomeroy, from the State Medical Society of Ohio.

A number of applications for membership were received and referred to the Board of Censors.

REPORTS.

The report of the Committee on Publication was presented by the Chairman, Dr. J. E. Reeves. Among other items, the Committee reported adversely on a proposition referred to it last year, looking to

THE ESTABLISHMENT OF A MEDICAL JOURNAL

in lieu of the annual volume of *Transactions*. The Committee thought the profession already has more than a sufficient number of journals, and that the effort to start a new one in West Virginia would probably prove a failure from want of adequate support.

The annual report of the Treasurer showed the Society to be in a good financial condition, a considerable balance being carried over from last year.

The Secretary's report indicated a small increase in the membership of the Society. Four members have died during the year.

A REPORT ON CLIMATOLOGY AND EPIDEMICS,

by DR. R. W. HALL, Chairman of the Committee, was read by the Secretary. The author gave a brief account of the climatology of the State, spoke generally of the effects of our mountains and high hills on air currents, and, indirectly, on the humidity and temperature of the atmosphere.

"It may perhaps be thought that during the hot months the mortality would likely be highest from diseases of the alimentary canal; yet we are persuaded, from the results of our inquiries throughout the State, that were we to deduct the deaths from bowel complaints from the deaths caused by diseases of the organs of respiration, there would be found a large per cent. still to remain. We therefore infer that the highest mortality is during that period when the earth's surface is cooler than the surrounding atmosphere, and that persons living on high hills are less likely to be afflicted with diseases of the organs of respiration, or diseases resulting from sudden changes of temperature, than are those living in the low valleys."

The remainder of the report contained very brief allusions to some of the more prevalent diseases during the past year. "The State has been unusually favored during the year, not having had any severe epidemic. The diseases most prevalent have been those of the respiratory apparatus. Bronchitis heads the list. This disease among children was frequently of the capillary variety, and such cases were attended, as usual, with a high rate of mortality. Next in frequency was pneumonia, which was usually very fatal, especially where it attacked both lungs. Laryngitis comes next, occurring in many parts of the State, notably in the eastern and northwestern sections. The disease generally commenced like an ordinary cold, ran a definite course, and usually ended in recovery. Pharyngitis also occupied a prominent place in the list of prevailing diseases, but the average duration was short, and the disease mild and manageable. Diphtheria prevailed over nearly two-thirds of the whole State. Typhoid fever has been present in nearly every section of the State, but has not been epidemic. Several epidemics of measles occurred in different localities of the State, most notably in Harrison and Marshall Counties.

The Board of Censors reported favorably on the applications of the following physicians, who were then

ELECTED TO MEMBERSHIP:

Drs. J. W. Cooper, of Willsburg; John L. Dickey, of Wheeling; Eugene Hoyt, of Wheeling; A. L. Hupp, of Lumberport; Bascome Baker, of St. George; S. H. Austin, of Lewisburg; O. T. Bond, of Rockford; C. C. Hersman, of Weston; L. D. Frum, of Sardis; M. J. Brabelle, of Clarksburg.

THURSDAY, MAY 22D—SECOND DAY.

DR. C. T. RICHARDSON, FIRST VICE-PRESIDENT, in the Chair.

A REPORT ON NEW REMEDIES,

prepared by Dr. REED M. BAIRD, of Wheeling, was read by the Secretary. The remedies discussed were *convallaria*, of which the writer remarked that "all reports of results agree that it is inferior to digitalis as a cardiac tonic," jequirity, kairin, and paraldehyde.

DR. FLEMING HOWELL, of Clarksburg, then reported

A CASE OF ŒSOPHAGOTOMY FOR THE EXTRACTION OF A SILVER FIFTY-CENT PIECE.

(See page 639.)

DR. BLAND, Superintendent of the State Asylum for the Insane, stated that Dr. Camden and himself had performed this operation on one of the patients in the Asylum, for the removal of a fish-bone, but the case terminated fatally.

EXPERT TESTIMONY.

The following resolution, offered by Dr. Fleming Howell, was adopted:

Resolved, That a committee of four members of this Society be appointed, whose duty it shall be to memorialize our next Legislature upon the subject of expert testimony, and to endeavor to secure the passage of a law giving to physicians who are summoned before the courts of the State as experts an extra special fee, to be determined by the court.

Drs. George Baird, J. E. Reeves, L. D. Wilson, and Fleming Howell were appointed the committee.

DR. GEORGE H. ROHÉ, of Baltimore, read a paper on the

TREATMENT OF THE LATER SYPHILITIC LESIONS OF THE SKIN AND SUBCUTANEOUS CONNECTIVE TISSUE,

in which he expressed the opinion that the view of Hutchinson, that the so-called tertiary manifestations of syphilis are merely sequelæ, and not symptoms of the syphilis, could not be accepted without more definite evidence in its favor than has as yet been furnished.

The tubercular syphilide and the subcutaneous gummata were regarded as anatomically identical. The author said the prognosis of syphilis was generally fav-

orable. He regards it as a curable disease, and deprecates the hopeless prognosis given by so many authorities. In the treatment of tertiary syphilitic lesions, iodide of potassium holds the first place. It should be given in free doses; twenty grains, four to six times daily, are sometimes necessary to produce the effect desired. Mercury is of much less value in this than in the secondary period, but should not be entirely omitted. Tonics are of importance in all stages to counteract the spoliative effect of the disease upon the red corpuscles. Good food, fresh air, cleanliness, and moderate exercise should be insisted upon. Cod-liver oil and iron, in the form of tincture of the chloride or pills of the protocarbonate, are often indicated. Locally, the application of mercurial plaster to the lesions before ulceration, assists in promoting their absorption. After ulceration, the syphilitic infiltration should be scraped out with the curette, and iodoform applied.

DR. W. H. SHARP, of Volcano, next read a paper entitled

LISTERISM IN OBSTETRICS—SHALL WE ADOPT IT IN GENERAL PRACTICE?

It contained an exhaustive review of the recent literature. It referred to the small mortality from puerperal affections even in large cities, and claimed that in smaller towns and in the country puerperal fever is a rare disease. Statistics were given which tend to show that in this country the enforcement of such stringent rules as are often laid down are not necessary. Nor is it necessary to practise so strictly personal disinfection when attending infectious cases.

DR. J. W. CHAMBERS, delegate from the Medico-Chirurgical Faculty of Maryland, then read a paper on *Cerebral Localization, with Illustrative Cases.*

DR. J. P. MILLER read a paper on *Phthisis; its Successful Treatment.*

A paper by DR. J. E. REEVES, *The Importance of the Microscope in the Practice of Medicine, with Illustrations*, was read by title and referred to the Committee on Publication, the author having been prevented by recent illness from completing it in time for the meeting.

DR. C. M. FRISSELL read a paper prepared by his venerable father, Dr. John Frissell. A number of surgical cases of greater or less interest were detailed. One was

A CASE OF ABSENCE OF VAGINA, UTERUS, AND OVARIES

in a married woman æt. 33 years. In external appearance the mons veneris, labia majora, the nymphæ, clitoris, orifice of the urethra (large enough to admit the forefinger), and the hair covering the parts, were all natural. Below the dilated orifice of the urethra was a small sulcus, but there was a perfect closure of the entire region that should have formed the external opening of the vagina. She had never menstruated, but did not think much of that, for she supposed some girls were troubled in the same way. Her sexual appetite, she thought, had been about the same as that of other girls. The breasts were not large, but appeared normal. Her general appearance was that of "a perfectly developed woman." At a second examination, the doctor "introduced a catheter into the bladder, and the fore and middle fingers of the left hand into the rectum. Through the wall of the rectum and the thick layer of cellular tissue he could feel the catheter in the bladder, but failed to find any solid body that he thought was the uterus or its appendages." The following operation was performed: After cutting out enough of the skin to make about a natural sized opening for the vagina, thus fairly gaining admission into the cellular tissue, he separated the layers with the right forefinger, holding the perineal tissue with the left thumb, the first and second fingers in the rectum forming a floor upon which to work. With the catheter above in the bladder and fingers below in the rectum, he could evenly direct his way about equidistant between these organs, and succeeded in making a division as far as he could reach with his right forefinger. He then placed in the opening a rectal dilator, and gradually spread the parts open until there was ample room for dilatation and contraction. He then introduced a bivalve vaginal speculum, and through it passed in pledgets of borated cotton saturated with carbolized water, each having a string attached, until the cavity was well filled. There was but little hemorrhage. The woman complained very little of pain, although, at her own request, no anæsthetic was given. The pledgets of cotton were changed every day or two for a week, when glass dilators were substituted. In about twelve days the patient left the hospital, well satisfied with the result of the operation. She took dilators of two sizes with her, promising to report if everything did not do well. She has not since made her appearance.

THE ELECTION OF OFFICERS

for the ensuing year resulted as follows:

President.—Dr. George Baird, of Wheeling.

Vice-Presidents.—Drs. T. A. Harris, of Parkersburg; R. R. Frey, of Terra Alta; and S. H. Austin, of Lewisburg.

Treasurer.—Dr. John A. Campbell, of Wheeling.

Secretary.—Dr. S. L. Jepson. of Wheeling.

Board of Censors.—Drs. J. H. Manown, L. C. Hunt, J. H. Brownfield, J. O. Wall, J. M. Bowcock, W. J. Bland, and B. W. Allen.

Weston was selected as the *place of meeting* for next year's session.

After the usual resolutions of thanks, the Society adjourned.

NEWS ITEMS.

LONDON.

(*From our Special Correspondent.*)

THE LONDON MEDICAL SOCIETIES.—The activities of the sessions of the medical societies are on the wane. The *Medical Society*—the last to begin, and the first to end, though during its session the most occupied—closed its meetings on May 5 last, when a *conversazione*, preceded by the annual oration, delivered by Dr. Theodore Williams, was held. No less than four of the principal societies met last week. The proceedings of the *Pathological Society* were not of the liveliest, and most of the members voted the evening flat. There was a large exhibition of card specimens, and this was certainly the most entertaining portion of the work.

At the *Ophthalmological Society* several good drawings were shown. Dr. Stephen Mackenzie read a paper

on extreme tortuosity of the retinal vessels. Mr. Morton communicated a paper on hemorrhage about the yellow spot which, as Mr. Jonathan Hutchinson observed, seemed to be related in some way to the gouty diathesis. A drawing was exhibited by Mr. Nettleship illustrative of peculiar changes in the choroid after papillitis taken from a man with symptoms of cerebral tumor. Straight parallel pigmented lines were to be seen, which, it appeared, might be produced by puckerings of the choroid, or might have been the consequence of a previous œdema. A remarkable case of "Tay's" choroiditis, or central guttate choroiditis, with perfect preservation of sight, was spoken of, and a colored drawing shown. This patient had also entire paralysis of accommodation, although she was not of that age at which presbyopia is mostly found. Dr. Adam Frost exhibited a specimen of ossification of the choroid giving rise to repeated attacks of sympathetic irritation. The bony stuff was the result of an injury sustained three years previously. Other examples of detachment of the retina—one from injury and another from blood-clot—were shown. The question of monocular diplopia came under consideration from a paper read by Dr. James Anderson and Mr. Gunn. Many members discussed this paper, and there seemed to be a concurrence of opinion on one point, viz., that when this peculiar form of diplopia was present, there generally also existed some weakness of the external rectus of the same eye. A case of nævus of the choroid also attracted some attention. It was associated with a port-wine mark on the face of the same side. Dr. Stephen Mackenzie referred to Dr. Allen Sturge's case of epileptiform seizures on the opposite side of the body to the nævoid condition of the face and choroid. The suggestion was made by Dr. Sturge that the epileptiform attacks might have been due to a similar condition of some of the cerebral vessels. Dr. Brailey was interested in the apparent determination of coarse tissue-changes by the vascular disease of the choroid. There was a layer of fibrous appearance, and in this was a small plaque, bony, or something like bone. In nævoid skin, no such alterations could be detected. Mr. Nettleship also referred to Dr. Sturge's case in this respect for myopia, and a darker tint existed in the choroid which possessed the tortuous vessels.

At the *Clinical Society*, the chief interest of the last weeks was surgical, though widely different regions were dealt with. Mr. Clutton read a paper on a case of intestinal obstruction, due to a Meckel's diverticulum, in a boy aged ten years. This case was treated by abdominal section, with recovery. The operation was performed on the third day of the disease. Mr. Treves spoke on the paper, and remarked that out of thirty cases of operations for intestinal obstruction, collected by Peyrot, only eight recovered; out of this number, four cases were due to strangulation by a diverticulum, and of these there was but one recovery. Mr. Treves had brought together twice Peyrot's number of cases, without arriving at a different result; but it must be remembered that there was a great tendency for operators to record successful, and not to publish unsuccessful cases. Dr. Coupland congratulated Mr. Clutton on his success, which he thought was due to prompt interference. Many interesting details were mentioned, amongst them one in which a depression at the umbilicus was found to be due to traction from a persistent vitelline duct, distended with intestinal material, and adherent at the navel. Dr. Mahomed did not agree with the statement made by Mr. Treves, that complete obstruction is always associated with continuous, and not a paroxysmal pain. Mr. Lymonds thought that a median incision was to be preferred in all cases. Mr. Henry Morris mentioned a case of reduction of left inguinal hernia *en masse*, in which, by a median abdominal section, he had relieved the constricted gut. Dr. Christopher Heath followed with a short paper on the treatment of recent fractures of the patella. He advocated the aspiration of the joint, so as to relieve the fluid distention; but showed cases which he regarded as so good that Lister's plan of wiring the fragments together was considered an unnecessarily severe procedure. The discussion on this occasion was not warm. It could not compare with the heat of the debate on the same subject at the Medical Society in the early part of the session. We could not say, "even our ashes glow with their wonted fire!" Dr. Whipham read notes of a case of hydrocephalus, followed by insanity and death.

Quarantine Conference.—A conference of State Board of Health Officers of the Gulf States is to be held at New Orleans on the 2d prox., for the purpose of considering the best means of protecting those States from yellow fever. A somewhat similar conference is to be held by some of the Northern State health officers at Brooklyn, New York, next month, who meet to devise some plan for a general quarantine for the United States.

Quarantine Precautions in Texas.—The State of Texas has virtually declared non-intercourse with all ports and places south of 25° north latitude, and Matamoras quarantines all travel by land from points south.

Cholera.—Weekly consular reports from Calcutta show an increasing mortality from cholera, as follows: For the week ending March 29th, 157 deaths; week ending April 5th, 177 deaths; week ending April 12th, 253 deaths. The consul further states that "the death rate is very high and the cholera is very severe in the northern town."

Yellow Fever.—Consular reports from Rio de Janeiro show 59 deaths from yellow fever at that place for the two weeks ending April 19th.

Central New York Medical Association.—At the annual meeting of this Association, which is composed of delegates from eight central counties of the State of New York, held May 20th, Dr. Ely Van de Warker, of Syracuse, was elected president, receiving twenty-two votes against seven cast for the "New Code" candidate.

The German Cholera Commission, Drs. Koch, Gaffky, and Fischer, returned to Berlin from Calcutta on May 3d. Dr. Ewald, in an editorial announcement of their arrival, in the *Berliner klinische Wochenschrift* of May 12th, says: "It is seldom that a scientific expedition is conducted with so great moderation in every respect, and for every interest, as this,

upon which the eyes of the nation, from the Emperor down to the most obscure man, have been directed with active interest."

The Commission has been received with great honors, but the honors of the Government have not been empty. In the Reichstag, Herr von Bötticher brought forward a Bill to place the sum of 135,000 marks (over $30,000) at the disposal of the Emperor, in order to reward the members of the German Cholera Commission for their brilliant and important discoveries in Egypt and India. Herr von Bötticher, in proposing the bestowal of the honorarium, spoke in very graceful terms of the services of this Commission: "It was entirely owing to Dr. Koch's readiness to place himself at their disposal that the Government was able to send out the Commission so quickly." The Bill was passed, on May 13th, by acclamation, when Professor Virchow welcomed this, the first occasion, as he said, on which he had ever been able to give his full support to the Government, and paid a high compliment to the energy, the diligence, the intelligence, and the disregard of danger, which had won for German science such a splendid victory. But, though Dr. Koch had discovered the bacillus or germ of cholera, medical men should not be too sanguine about the future prevention and cure of the disease.

Of the sum, 100,000 marks will be assigned to Dr. Koch, the chief of the Commission, and the rest divided among his colleagues. A less substantial, though equally honorable, reward has been conferred on Dr. Koch, in the shape of a high decoration—the Crown Order of the second class, with the star; and Fischer and Gaffky with the Order of the Red Eagle. Lastly, at a sitting the other day of the Imperial Board of Health, the great nosological explorer, in addition to being officially eulogized for his successful researches, was presented with a life-size bust of the Emperor, by a distinguished German sculptor.

The Presentation of Prof. Stillé's Portrait to the University of Pennsylvania.—The fact that the late Commencement of the University of Pennsylvania was the last one at which Prof. Alfred Stillé would appear as an active teacher, made the occasion one of unusual interest. The President of the Graduating Class, Dr. Batchelor, presented to the Trustees, for the class, a full-length portrait of Prof. Stillé, and made a neat and appropriate address.

Dr. Weir Mitchell, as Chairman of the Committee on the Department of Medicine, received the picture for the Trustees in the following speech:

Our present commencement exercises will be memorable for most of us, because with them we lose the services of Alfred Stillé, now for twenty years Professor of the Theory and Practice of Medicine in the University of Pennsylvania. In accordance with an ancient usage, the medical class which has the honor to be the last which shall hear him lecture presents to-day his portrait to the University. In the name of the Trustees, and as Chairman of their Committee on the Department of Medicine, it is my very pleasant duty to accept the gift and to thank those who give it. It has been the habit on these occasions to add little to the remarks made by the orator who speaks for the class, but as this is the last time when Professor Stillé is associated with us officially in public, I should misrepresent my colleagues of the Trustees if I did not frankly use the opportunity to say how pleasant have been our mutual relations, and how honest is our regret that he can aid us no longer. There are many good men who do their duty well in life, and who, stepping aside, fail to leave with those for whom they labored and who may have loved them, any strong or vivid remembrance. There are others who are so distinct as individuals, so impressive as human beings, that over and above the intellectual work they perform, they insist, as it were, by the value of many social qualifications, in being remembered and readily brought back to mind. Of this latter class is the man we part with to-day—a man not lightly to be let go and not easy to forget.

Henceforward, we can claim from him only encouragement and moral support. He has said for us and to you his last words of wisdom and instructive counsel, and for him the hour must have a solemnity of parting akin to that graver cessation of duties which soon or late will come to one and all of us. He has lived with us long enough to see that which he has through his life written for and spoken for—the lifting of medical education to a place which makes your diplomas the best, because the hardest to get, in this country. He may feel sure, also, that we mean every year to make them harder to win, until we place the medical education of this University on a level which would satisfy even the affectionate ambition for his *Alma Mater* of the Professor we part with to-day. Let us congratulate him on having lived to see his ideas victorious, and thank him, in the name of all physicians, for his share of the work.

Here, to-day, I can hardly say of him what as colleagues, friends, or Trustees we feel, as the natural expression of long years of pleasant association without a sensation that he may shrink from what he would call flattery. But for the classes before me, for you at least I may speak in anticipation of the just verdict of your future years. In days to come, when you are middle-aged or gray, and rich like him in the good opinions of your fellows, many of you, returning to our halls, will stray through the great Museum, in which shall hang this portrait of your master and friend. I can imagine you then passing in review the thought-filled face of Rush, the gently humorous look of Chapman, the gravity and pleasantness of Wood, the countenance earnest almost to anxiety of the elder Pepper, and pausing, full of memories, before this picture of a man well liked, to recall the share he had in modelling your lives in those plastic hours when the soft clays of youth were hardening into the characterizing lines of manhood.

If, in those years of fulfilment, you have risen by honorable means to places of trust, you will feel that you owe something to him who but of late taught you with the impressiveness of one speaking for the last time to you, that "only two things are essential, to live uprightly and to be industrious." I thought, as I read his words, that they made up a pleasant little bit of autobiography. If, in days of personal sorrows, and of the calamities that await us all in life; or if, weary with the sad company of pain, or depressed by defeat in some vain struggle against death—if then you turn to books for an hour of forgetfulness, you will recall with gratitude that it was this scholarly lover of books, whose portrait reminds you of the time when he taught you

this solace, and helped by word and example to give you a constant and reverent love for the great dead—dead but yet alive, as souls live. I can imagine you thus, reflecting how strangely some men get their characters into their faces, as you have brought back to you by the strong and refined lineaments of his picture that expression of courteous gravity in the teacher who taught you by the subtle education of each day's contact in the lecture-room, how attractive is the charm of manners which are the outcome of thoughtfulness of others, and belong to the very poetry of social conduct.

You who have lived by his lessons will owe him in truth a just debt, if being a scholar he taught you to love books, if being a writer he showed you an example of accuracy, constructive skill, and high critical acumen unstained by personalities, if being a physician he taught you to hold fast to honorable and reasonable traditions.

Prof. Stillé has told you in the grave and high-minded address with which he closed his career as a teacher, that no true man lives up to his ideals, because the great world of self-demands grows, widening before us with increase of knowledge, like the horizon of the growing morning with increase of light. But no matter what may be his own severity of self-judgment to-day, we, at least, who have known him well in certain relations as you have in others, must feel that we cannot let him go hence without assuring him how well his life-work with us has illustrated the best standards of the teacher, the physician, and the gentleman.

Let me hope for you to whom we are indebted for this portrait of Alfred Stillé that when each of you, too, comes to lay down your burdens it may be with a soul as justly tranquil as his must be in the reassuring consciousness of duties amply done, and amidst regrets which will then be deepest among those who know you best.

And now, finally, in the name of the Trustees of the University of Pennsylvania, I thank Professor Stillé for the noble work of his twenty years of teaching, and beg him to feel sure that in placing his portrait in the goodly fellowship of his predecessors we recognize what his life, his lectures, and his writings have done to add to our strength and to embellish our most cherished traditions. Personally, and for the great profession to which we both belong, I thank him for the fair example of a true and wholesome and dutiful life, and wish him in his retirement many years of health and strength, and, as Bacon said, goodly and bountiful company of friendly books.

A New Thermostat.—Dr. Reichert, of the University of Pennsylvania, has made an important advancement in the construction of thermostats. He has invented an instrument which is graduated and can be set before using for any temperature between 20° C. and 100° C., or over, and which works with considerable accuracy. The construction is simple, and the principle of its action essentially the same as in other thermostats, being dependent upon the expansion of air which forces a column of mercury in a tube in contact with a cut-off for the supply of gas, so that when a proper temperature is reached the supply of gas is automatically cut off, or if the temperature becomes diminished is allowed to flow. The range of temperature is obtained by the use of a graduated plunger of peculiar construction which forces the column of mercury towards or from the cut-off, thus necessitating the presence of a less or greater amount of heat to maintain the column of mercury at this point.

The American Climatological Association.—The first annual meeting of the American Climatological Association was held in Washington, D. C., May 3d and 5th. In the absence of Prof. Loomis, the President, Dr. F. I. Knight, of Boston, the first Vice-President, occupied the Chair.

The first day was occupied in adopting a suitable constitution and by-laws. The second day was devoted to the reading of papers as follows: Address by the Presiding Officer, Dr. Knight. "The Etiology of Pulmonary Phthisis," by Dr. B. F. Westbrook, of Brooklyn; "The Effects of Sea Air upon Diseases of the Respiratory Organs," by Dr. Boardman Reed, of Atlantic City; "The Relation of Laryngeal Disease to Pulmonary Diseases," by Dr. F. H. Bosworth, of New York; by Dr. Charles Dennison, of Denver, Col., on "Dryness," in which he dwelt on the following points: "Variability *versus* Equability. A rule for classifying climates as to desirability, based upon low, absolute and relative humidities, and preponderance of sunshine. The influence of elevation, sunshine, cold, etc., in producing desirable dryness. The physical effect of dryness on man;" "City Life and City Air Injurious to Consumptives," by Dr. Donaldson, of Baltimore; "The Use of Compressed and Rarefied Air as a Substitute for a Change of Climate in the Treatment of Pulmonary Diseases," By Dr. J. Solis Cohen, of Philadelphia.

The following officers were elected for the ensuing year:

President.—Prof. A. L. Loomis, of New York.

Vice-Presidents.—Drs. F. I. Knight, of Boston, and W. H. Geddings, of Aikens, South Carolina.

Secretary and Treasurer.—Dr. J. B. Walker, of Philadelphia.

Council.—Drs. J. H. Tyndale, of New York; E. T. Bruen, of Philadelphia; E. D. Hudson, of New York; Frank Donaldson, of Baltimore; Beverly Robinson, of New York.

State Medical Society Meetings.—The Kentucky State Medical Society will meet at Bowling Green, on Tuesday, June 3d, and the Wisconsin State Medical Society will meet at Milwaukee on the same day.

Ontario Medical Association.—The fourth annual meeting of the Ontario Medical Association will be held at Hamilton, on Wednesday and Thursday, June 4 and 5 next.

The Medical College of Virginia.—The Board of Visitors of the Medical College of Virginia met a few days ago for the purpose of electing professors to the following chairs: To the Chair of Obstetrics, made vacant by the death of Prof. Coleman; to the Chair of Practice of Medicine, made vacant by the resignation of Prof. McCaw; to the Chair of Anatomy, made vacant by the resignation of Prof. Tompkins; to the Chair of Materia Medica and Therapeutics, made vacant by the resignation of Prof. James.

R. T. Hubard, John F. Lewis, George Harrison, and R. B. Berkeley, who were appointed by Gov. Cameron to fill vacancies on the Board, appeared and presented their commissions. The Board decided to postpone the election of professors until the 6th of June, to accommodate the new members.

LONG ISLAND COLLEGE HOSPITAL.—The twenty-first annual commencement of this institution was held on May 21st, in the Brooklyn Academy of Music. The degree of M.D. was conferred upon forty-four graduates.

OBITUARY RECORD.—CHARLES ADOLPHE WURTZ, the distinguished chemist, a member of the Institute and of the Academy of Medicine, died in Paris on Monday, May 12th, in the sixty-seventh year of his age. He was born in Strassburg in 1817. He studied in the School of Medicine in Strassburg, and from 1839 to 1844 was Instructor in Chemistry. In 1845 he went to Paris, to take charge of the department of Organic Chemistry in the Medical Faculty of the University. He was made a member of the Academy of Medicine in 1856. In 1875 he was made Professor of Organic Chemistry in the Scientific Faculty. He was the recipient, in 1865, of the Biennial Prize of the Academy of Sciences, and 20,000 francs, established by the Emperor, and in 1878 of the Faraday Medal of the English Royal Society. In 1867 he was elected to the Academy of Sciences as the successor of M. Pelouze. He made many important discoveries in chemistry, which were made the subject of elaborate memoirs, and contributed to the *Annales de Chimie et Physique* and to the *Répertoire de Chimie Pure*. He had been the editor of the latter since 1858. He published many separate treatises on chemical subjects.

NOTES AND QUERIES.

DR. SUTTON'S STATISTICS OF ABDOMINAL SURGERY.

To the Editor of THE MEDICAL NEWS.

SIR: In the issue of your valuable Journal for this date, in the report of the meeting at Washington, the following occurs: "Dr. Sutton, in conclusion, said that the statement of the low foreign mortality and its causes had not been refuted; his own first seven cases were fatal. After having observed the practice abroad for eighteen months, and having again had four failures in succession, he perceived his error and opened a private hospital. His seven ovariotomies therein performed have all been successful, and his highest temperature rise has been 101.5 F."

This statement, so far as it relates to my statistics, is incorrect. I have opened the abdomen nineteen times. Of these patients, eleven have recovered and eight have died—*a mighty bad record in view of foreign statistics*. But, out of my first seven cases, three recovered. These were done before I went abroad. After my return I lost four out of my first five cases. My last seven, done in my private hospital, have all recovered. These nineteen abdominal sections were made for a variety of abdominal diseases.

Of the eleven patients who are living, one was subjected to ovariotomy plus enterotomy; four inches of the small intestine were removed. Two had supravaginal amputation of the uterus and both ovaries; one had double ovariotomy for large cystic ovaries and supravaginal amputation of the uterus at the same time. In two the tumors were multilocular, thirty-eight and forty-six pounds respectively, with extensive adhesions to the liver and intestines. In another a cyst was ruptured, and there was slight peritonitis at the time of operation. Nearly all the ovarian tumor cases had been tapped, several of them frequently, and only three of the eleven laparotomies were simple cases. Of the eight which were lost, there was not one simple case. So the record stands, 19 laparotomies, with 11 recoveries and 8 deaths.

Among the eleven cases of recovery, six children have been born to two mothers; one operated on in 1875 and one in 1876. If we add these six lives to the eleven cases of recovery, it gives us seventeen lives directly the result of my nineteen laparotomies. Therefore, if the books are kept right on the "other side," I am nearly square. Very truly yours,

R. STANSBURY SUTTON, M.D.

PITTSBURG, May 10, 1884.

SKIN AFFECTIONS FOLLOWING THE ADMINISTRATION OF BORAX.

To the Editor of THE MEDICAL NEWS.

SIR: Will you kindly grant me the use of your correspondence columns to request from any physician, who may have observed squamous or other pathological conditions of the skin following the internal administration of borax (whether for epilepsy or not), very brief notes of the cases for publication?

Treatises upon diseases of the skin do not appear to recognize such conditions; yet they have been observed in England by Gowers, and other writers upon mental and nervous diseases, as also in Boston, in this country.

Very respectfully,

EDWARD WIGGLESWORTH, M.D.

79 BOYLSTON STREET, BOSTON, MASS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 13 TO MAY 26, 1884.

WATERS, WILLIAM E., *Major and Surgeon.*—Ordered to report for temporary duty to the Commanding Officer at Plattsburg Barracks, N. Y.—*Par. 4, S. O. 90, Headquarters Department of the East*, May 10, 1884.

HUBBARD, VAN BUREN, *Major and Surgeon.*—Relieved from further duty at Fort Stanton, N. M., and ordered to Fort Bayard, N. M., for duty.—*Par. 3, S. O. 96, Headquarters Department of Missouri*, May 12, 1884.

MOSELEY, E. B., *Captain and Assistant Surgeon.*—Assigned to temporary duty at Vancouver Barracks, Wash. Terr.—*Par. 6, S. O. 59, Headquarters Department of Columbia*, May 8, 1884.

WILCOX, TIMOTHY E., *Captain and Assistant Surgeon.*—Assigned to duty at Washington Barracks, D. C.—*Par. 2, S. O. 90, Headquarters Department of the East*, May 10, 1884.

WALES, P. G., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Old Fort Colville, Wash. Terr., until further orders.—*Par. 3, S. O. 58, Headquarters Department of Columbia*, May 7, 1884.

STERNBERG, GEORGE M., *Major and Surgeon.*—Relieved from duty in the Department of the East, and ordered to report to the Surgeon-General of the Army for temporary duty.—*Par. 2, S. O. 115, A. G. O.*, May 17, 1884.

MAGRUDER, DAVID L., *Lieutenant-Colonel and Surgeon.*—Ordered to be relieved from duty as Medical Director, Department of the Missouri, and to proceed to Philadelphia, Penna., and assume duties of Attending Surgeon and Examiner of Recruits in that city.

FRYER, BLENCOWE E., *Major and Surgeon.*—From Department of Missouri to Department of Dakota.

EWEN, CLARENCE, *Captain and Assistant Surgeon.*—From Department of Missouri to Department of the Platte.

STRONG, NORTON, *First Lieutenant and Assistant Surgeon.*—From Department of the Platte to Department of Missouri.—*Par. 7, S. O. 113, A. G. O.*, May 17, 1884.

HALL, WM. R., *Captain and Assistant Surgeon.*—Assigned to duty at Fort Stockton, Texas.—*Par. 1, S. O. 63, Headquarters Department of Texas*, May 19, 1884.

WILSON, GEORGE F., *First Lieutenant and Assistant Surgeon.*—Ordered to proceed to Fort Canby, Wash. Terr., for temporary duty at that post, relieving Assistant Surgeon W. O. Owen, Jr., U. S. A., who will report in person at these Headquarters for further orders.—*Par. 5, S. O. 62, Headquarters Department of Columbia*, May 12, 1884.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLIV. SATURDAY, JUNE 7, 1884. No. 23

ORIGINAL ARTICLES.

PRACTICAL SUGGESTIONS UPON THE ALIMENTATION OF PATIENTS SUFFERING FROM DYSPHAGIA.[1]

BY D. BRYSON DELAVAN, M.D.,

SECRETARY OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION; LARYNGOSCOPIC SURGEON TO THE DEMILT DISPENSARY, ETC.

FEW expressions suggest to the mind of the experienced physician so much of extreme suffering as does the word dysphagia. To the patient, already enfeebled by irremediable constitutional disease, and requiring all the help which good nourishment can afford, this symptom comes as an overwhelming blow, which effectually crushes out all hope for life and for comfort which may remain. Again, when safety lies in the successful passage of a dangerous crisis, the want of proper sustentation will often prove disastrous, while, in cases of less apparent danger, the demoralizing effects of severe dysphagia are often most serious. We may well be impressed with the important relations which it bears toward the general well-being of the patient, and the urgent necessity which always exists for its relief.

The object of this paper will be to remind you of the morbid conditions with which dysphagia may be prominently associated; to discuss briefly its direct influence upon these conditions; to suggest for its relief some methods which have heretofore not been fully appreciated and utilized; and, finally, to urge the prompt employment of these methods in all cases in which they are likely to be of service. Dysphagia may be caused by organic, by functional, or by surgical derangement of one or more of the parts concerned in deglutition. Again, these derangements may be either acute or chronic, remediable or irremediable, so that the indications to be met, and the end to be attained, cover a wide and varied field.

The *organic* derangements which most frequently cause dysphagia are: *a*. Tuberculosis; *b*. Cancer; *c*. Syphilis; *d*. Diphtheria; *e*. Tonsillitis; *f*. Parotitis; *g*. Retro-pharyngeal abscess.

The *functional* derangements are: *a*. Spasm of the pharyngeal constrictors; *b*. Paralyses.

The *surgical* conditions are: Operations upon and injuries to—*a*. The soft and hard palate and uvula; *b*. The tonsils; *c*. The pharynx; and, *d*. The larynx.

In all of these conditions, the act of deglutition will produce:

1. Pain, either local or reflex; or,

2. Mechanical or chemical injury to parts already inflamed or ulcerated; or it may cause both.

These, and especially the first, may, not only by interfering with the ingestion of food, but also, by the depressing effect upon the nervous system of frequently recurring shock, result in:

3. Impairment of nutrition.

The general indications to be met would therefore be:

1. The securing of rest, and avoidance of causes which excite pain.

2. Protection of the parts from mechanical or chemical injury.

3. The maintenance of nutrition.

Heretofore, the resources for meeting these indications have been crude, limited, and ineffectual. Thus, in tubercular or cancerous ulceration of the throat, the patient, unable to swallow either solid or liquid food, has been directed to bolt quickly an unbeaten raw egg, or a raw oyster, or some such semi-liquid, and yet coherent bolus as should contain the greatest amount of nutriment in the least possible compass, and in this manner reduce the number of acts of deglutition to a minimum. Meanwhile, in spite of local anodynes and healing applications, pain and injury have been steadily augmented, and, in the unequal struggle for life, the patient never taking at any one time food enough to supply the demands of nature, has surely lost ground. Again, in severe acute affections of the throat, the patient will often decline to take any nourishment whatever, until the severity of the attack shall have subsided, thus adding to the enfeeblement caused by the disease itself, and protracting the period of convalescence.

In the neurotic and surgical affections before referred to, the difficulties and objections to swallowing are evident.

Since the act of deglutition is the immediate cause of dysphagia, the most rational means for relieving the dysphagia would be, obviously, to remove the cause; in other words, to abolish the act of deglutition. This, in fact, is what it is proposed to do, and by the following methods:

I. When there exist both dysphagia and inability on the part of the stomach to retain food, a most invaluable resource lies in rectal alimentation, the utility of which has been so well established that it is only necessary, in the present connection, to call attention to the importance of its adoption early in the history of the case, and before the strength of the patient has been reduced by want of food.

II. When, on the other hand, the condition of the stomach is good, then, granting the desirability of alimentation by the natural passages, the indication is clearly either to remove the obstacle to deglutition or to avoid it. The former is impossible: the latter may, in most instances, be easily accomplished by means of the method which I am about to describe. You will recognize it at once as founded upon old and well-known ideas, and as embracing but few principles with which you are not already familiar; even though you may not have put them into actual practice. The basis of the method is

[1] Read before the New York Academy of Medicine, May 15, 1884.

founded upon the stomach-tube; which, discovered by Renault, in 1802; applied twenty-five years later by Physick, of Philadelphia, as an essential part of the stomach-pump; advocated by Küssmaul, in 1867, as a means for washing the stomach in certain forms of dyspepsia; and, finally, utilized by Débove and Dujardin-Beaumetz in their process of forced alimentation in phthisical and badly nourished patients, has not even yet received the wide application of which it is capable.

Unlike the old practice, however, namely, that of inserting a tube of large diameter through the œsophagus and actually into the stomach, the method herein advocated has as its basis the two following principles:

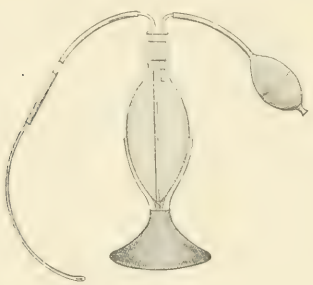
1st. *The employment of a tube of the smallest possible calibre*, and

2d. *The introduction of this tube, not into the stomach, but merely into the œsophagus and past the point of obstruction, or else past the pharyngeal constrictors.*

Through the tube the stomach may be made to receive food in almost any amount and variety, and that without any attempt at deglutition, and with perfect protection to the parts. Hence, it is evident that by that simple device all of the indications mentioned above will be completely met.

1. Pain is at once done away with and a maximum of rest to the pharynx is secured.
2. Injury is avoided, and
3. Nutrition is maintained.

The apparatus needed for this purpose is exceedingly simple. The one which in my hands has been the most convenient, consists of a receiver in the form of an ordinary conical-bottomed soda-water



bottle, into the mouth of which is fixed a tight-fitting India-rubber stopper. In this stopper are two perforations, through each of which passes a glass tube, one short, the other reaching to the bottom of the bottle, so that all of its contents may be exhausted without including any air. To the short tube is attached a Davidson's air-compressor, while the long one is connected with an English flexible woven catheter, of any size from 8 to 18, by means of about a yard of rubber tubing, the continuity of which is interrupted by an inch of glass tube, after the manner of the tube of the ordinary aspirator. A simpler contrivance even than this is the device of Faucher, who, instead of using an air-tight receiver, merely attaches to the end of the tube a glass funnel. An ordinary Davidson's syringe has sometimes been used.

The size of the catheter should be regulated by the age of the patient and the nature of the liquid to be introduced. It is better not to rely upon the lateral opening in the catheter, but to perforate it at its tip, so that the fluid may pass immediately and unobstructedly downward.

As to the liquids which it may be possible thus to employ, their variety is unlimited, while their consistency may be of considerable thickness and body, so that food of almost any desired class, and in any quantity, may be administered. For a full description of the preparations recommended by Débove and Dujardin-Beaumetz, I must refer you to the article upon "Lavage et Gavage," by the latter, or, better still, to the excellent paper upon the subject lately published in the *New York Medical Journal*, by Dr. Henry B. Millard, of this city. In injecting the fluid into the œsophagus it is generally necessary to proceed slowly, allowing, in an adult, not more than half an ounce to pass at once, and stopping for a few seconds before repeating the injection, so that, as far as possible, the natural physiological action may be imitated.

To the great advantage of the catheter over the large and clumsy stomach-tube, it is scarcely necessary to refer, as its introduction is much less startling and uncomfortable to the patient, and if the preparations referred to above be used, the large tube will be unnecessary. As a general rule, the irritation caused by the passage of the tube increases with its size. The tube should be introduced in the usual manner, namely, the patient's mouth being opened and his tongue protruded, the catheter should be carried to the base of the tongue, the patient told to swallow, and, as he does so, the catheter pushed into the œsophagus, and thence downward as far as may be deemed necessary. The larynx may be avoided with certainty by using the finger as a guide. Before its introduction the tube should be carefully lubricated, for which purpose white of egg, mucilage, or even milk, are useful. An excellent plan is to allow the patient to swallow slowly, just before the introduction of the catheter, a drachm or two of pretty thick mucilage. Vaseline, glycerine, and oil are unpleasant to the patient, and should on no account be used. In passing the catheter gentleness should be used, and great care taken to avoid, as far as possible, all points of special tenderness. In many cases the patient may be taught to pass the tube himself much more successfully and comfortably than it can be done for him, since the manœuvre is not a difficult one, and no one knows so well as he the exact situation of the painful spots. Sometimes, especially with children, the point of greatest irritability is in the palatine arches, and any attempt at passing a tube across them will be followed by violent gagging. In such cases a soft rubber tube may be passed through the nostril and pharynx, and thence into the œsophagus, and thus contact with the fauces be wholly avoided. Should the introduction of the tube cause dyspnœa, direct the patient to take full

breaths. It may also cause nausea when it passes the pharynx, for which Dujardin-Beaumetz advises the administration of bromide of potassium; and, also, when it reaches the stomach, in case it be inserted so far, for which the introduction of food will quickly bring relief.

Of course, the passage of the tube will not always prove an easy or a painless operation. A little practice, however, will render it possible in nearly every instance, while the advantages to be gained far outweigh any ordinary objection to the method. No one who recalls to his memory the delicious sensation of repose and satisfaction which has, to him hungry, followed the ingestion of a hearty meal, will fail to appreciate the comfort and relief which the tortured and starving unfortunate will derive from the use of this simple means.

Turning now from the general consideration of the subject, it will be well to study more particularly the special application of the methods just described.

Organic Derangements.—a. Tuberculosis. In no disease does dysphagia play a more important part than in this. Although the resources of modern therapeutics have rendered it possible to control, to some extent, the tuberculous ulcerative processes commonly found in the larynx and pharynx, still no amount of medication can counterbalance the evil effects of the local disturbance caused by deglutition; and, even in cases in which the ulcerations are confined to the interior of the larynx, beyond the reach of matters swallowed, deglutition is apt to provoke attacks of coughing which not only cause the food already taken to be vomited, but inflict additional injury upon the parts. When the ulcerations are external to the larynx, for example, upon the epiglottis, or in the region of the tonsils, the pain is more intense than in any other lesion of the throat. Thus nutrition is almost totally arrested at a time when life is most dependent upon it. In cases in which extensive degeneration has taken place in the lungs, and this condition must soon of itself prove fatal, dysphagia stands in the same relation that it does in cancer: the symptoms can only be palliated, and with little hope of prolonging life. In many instances, however, extensive ulceration of the larynx occurs long before the pulmonary lesion has progressed beyond control. By proper conditions of climate and *nutrition*, life may be prolonged indefinitely, so far as the lungs are concerned. But the dysphagia interferes with nutrition; strength to cope with the disease is not forthcoming; and so, through a cycle of unfavorable influences, the progress of the patient is from bad to worse, until, finally, he succumbs from inanition. It is in such cases that the results of treatment by the tube are most brilliant, for it will readily appear that, with a full and well-assimilated diet, the conditions under which the patient labors are materially altered, and the possibilities of recovery or of improvement infinitely increased.

b. Cancer. The most unpromising circumstances under which dysphagia is likely to occur will be found in some one of the various forms of cancerous disease which may attack the throat. The extreme liability to destructive ulceration in cancer of the mucous membrane renders dysphagia an early and prominent symptom. The pain in such cases increases with great rapidity, until a time comes when the dysphagia surpasses the limit of human endurance, and when the pangs of hunger are less intolerable than is the agony caused by each attempt to satisfy it. The condition of the patient is such that the history of suffering cannot furnish a parallel. No creature can be more miserable, none more hopeless. While it may not be desirable to prolong life under such circumstances, still the performance of tracheotomy when indicated is always regarded as a duty, and with equal justice the patient should be fed, and his pain relieved, even when there is no doubt as to what will be the final result. Here, again, the tube will prove a source of greatest comfort.

c. Syphilis. As in phthisis, so in syphilis nutrition plays an all-important part in the successful treatment of the case. Although the danger to life may not be so great as in phthisis, still in extensive secondary or tertiary disease of the throat it is by no means inconsiderable, while dysphagia is often very severe. The earlier the patient can be placed upon a full supporting diet the more quickly will he be likely to respond to constitutional treatment. The importance, therefore, of overcoming dysphagia and its effects is clear.

d. Diphtheria. In many cases of diphtheria, dysphagia is not a marked symptom. When, however, it exists, the tube should be immediately resorted to, in order that the heart's action may not be influenced by the depressing effects of pain; and, more particularly, because in this disease the question of nutrition is of such vital importance.

e. Tonsillitis. In all acute inflammatory affections of the tonsils, dysphagia is frequently so distressing that the patient will for several days refuse all food whatever. This, of course, adds to the duration and severity of the attack, and, therefore, protracts the period of convalescence. No one familiar with such cases can have failed to observe the beneficial effects of the first hearty meal which the patient is able to swallow. The inference naturally follows that nutrition should be maintained from the outset.

f. In Parotitis and (*g*) *Retro-pharyngeal abscess*, as in tonsillitis, dysphagia is frequently so distressing that the tube will be of great service.

Functional Derangements.—a. Spasm of the pharyngeal constrictors. Although this condition is rare, cases now and then occur in which the hyperæsthesia is so great that the power of swallowing is, for the time being, lost, so that, when it continues for any considerable length of time, the patient may suffer severely for want of food. A few well-assimilated meals would, from their tonic effect, probably contribute more than any other one thing toward the breaking up of the attack, as well as satisfying the immediate demands of hunger.

b. Faucial paralysis from any cause—from cerebral hemorrhage or embolism, or from diphtheria—is always a most important and annoying symptom from the well-known tendency of the food to get into the larynx. In his excellent work upon diphtheria, Prof. Jacobi suggests the value of the stomach-tube in diphtheritic paralysis.

Surgical Conditions.—As to the surgical conditions in which the tube will be of service, it is only necessary to mention them in order to suggest the great utility of the method. In all such cases it will be well to accustom the patient to the use of the tube *before* the operation, so that he will not be obliged to learn it under adverse circumstances.

I have dwelt thus particularly upon the details of the subject in hand, even at the risk of being prolix and elementary, because I believe that by a proper use of the methods described much distress may be done away with, and great good accomplished.

Some, doubtless, will object that the passage of the tube is likely to be disgusting, painful, or unnecessary, and that no sensitive or refined patient would submit to such a proceeding. My own experience, however, covering a period of nearly four years, and embracing a wide variety of subjects, together with the large and rapidly increasing mass of testimony both from home and from abroad, has satisfied me that the passage of the small tube is a comparatively easy matter, and that I am amply warranted in advocating the views herein advanced.

I would urge for the special method described a fair, patient, and intelligent trial in cases suitable for its employment, and am confident that, once having gained the limited amount of manipulative skill necessary for its use, it will be found, in a large proportion of cases at least, an indispensable resource, and an instrument most useful in the relief of suffering and in the prolongation of human life.

No. 1 East 33D St., New York

OSTEOTOMY FOR ANKYLOSIS AT THE HIP-JOINT.[1]

By CHARLES T. POORE, M.D.,
OF NEW YORK.

DEFORMITIES at the hip-joint, which may be relieved by an osteotomy, may be considered under four heads:

1. After hip-joint disease.
2. After rheumatism.
3. After unreduced dislocation.
4. After fracture united at an angle.

The great majority of deformities of this joint follow coxalgia. There are but few persons who have had suppurative disease of this articulation who recover with motion, and many, in whom there have been no signs of abscess, yet the joint remains stiff with an amount of flexion and adduction which interferes much with locomotion; or there may be some movement at the hip-joint; yet, on account of the contraction of the psoas and iliacus, and the adductors, the limb is flexed and adducted on the pelvis at an angle too great for easy locomotion; the foot cannot be planted firmly on the ground even with the greatest latitude of motion in the lumbar vertebræ, the gait being awkward and labored.

An ankylosed hip-joint in which the limb is held in a straight line with the bony axis of the body is a useful one for walking or standing, but it is more of a deformity in any other position of the body than one fixed at a right angle to the pelvis. In the former case the person cannot sit down with any degree of comfort or put on his shoes, whereas in the latter not only is the sitting posture comfortable, but, by the aid of proper orthopædic apparatus, locomotion can be performed with considerable facility. It therefore becomes an important question to solve at what angle an ankylosed hip should be placed so as to be a compromise, as it were, between these two positions, and give the patient the greatest amount of use—that is, easy walking and comfort in the sitting posture. I think that an angle of 125° with the long axis of the body gives this. This, then, taken as a standard, we are in a position to discuss the question of correcting any marked deviation on either side of this line.

The deformity after hip-joint disease is due, 1st, to contraction of the psoas and iliacus, causing flexion and rotation of the limb; 2d, to the action of the adductors drawing the limb toward the median line. This adduction is accompanied by tilting of the pelvis upwards upon the diseased side in walking in order to bring the limb in a line with the long axis of the body and prevent it crossing the sound one. It is a compensatory, not a pathological, position. In the early stage of the disease the apparent shortening is due to this tilting of the pelvis; later, in those cases in which changes take place in the head and acetabulum, there is actual shortening of the limb.

The difficulty in walking is not due so much to the shortening and flexion of the limb as to the adduction, whether the limb be ankylosed or not. The characteristic awkward gait of a patient who has recovered from coxalgia with ankylosis or limited motion is due to the hitching up of the pelvis on the diseased side at every step in order to get the limb out of the way of the sound one; in order to accomplish this the pelvis has to be raised so much in many cases that only the toes are able to touch the ground—even when the real shortening is slight.

As mentioned before, the muscles at fault are the psoas and iliacus, and the adductors, and even when it is attempted to correct the deformity by any operation above the insertion of the former, they will still prove an obstacle, and in many cases prevent the limb from being brought into a desirable position.

In those cases in which ankylosis does not take place, there may be motion in the direction of further flexion, but extension beyond a certain point is impossible, and although the thigh can be brought down so that the foot can be planted flat on the ground, it is not from any further extension, but is accomplished by bending forwards the lumbar portion of the spine and tilting downwards of the pelvis, due to shortening of the muscles inserted in the trochanter minor. In this class of cases walking is almost as difficult as when the joint is fixed in the same position when there is much adduction.

Absorption, more or less, of the head and neck of the femur and the higher plane occupied by the trochanter, due partly to the above-mentioned changes and partly to elongation of the acetabulum in its upper and posterior portion, increase in no small degree the deformity and the actual shortening of the limb.

[1] [illegible] N. Y. Surgical Society, May 27, 1884.

In ankylosis following rheumatic inflammation, the condition of the parts is entirely different. The bone is not infiltrated with inflammatory products of low vitality; it may be increased in hardness, but the parts retain their normal relation. The neck is not shortened, the ankylosis is usually bony, and the psoas and iliacus are not as much of an element in causing the deformity; it is due more to position, while in hip-joint disease it is the active contraction of these muscles that causes the flexion, etc. In this disease the limb may be fixed in a straight line with the long axis of the body, a condition seldom, if ever, met with after coxalgia.

In rheumatoid arthritis the joint may be surrounded by irregular bony growths, and the head and neck be very hard.

Deformities may occur after unreduced dislocation, the dislocation may be traumatic or pathological. The latter may occur during the course of hip disease, but I do not think it is as common as some writers would lead us to suppose. It may occur during the course of some debilitating disease as typhoid fever, scarlet fever, or acute rheumatism.

Malposition of the femur after fracture, high up, has been reported.

In forming an opinion in regard to the advisability in a case of performing an osteotomy for the relief of any deformity at the hip-joint, the amount of adduction should be considered more than the flexion. I think that we are apt to look more at the latter, while the former is the main hinderance to easy locomotion. I think that a moderately flexed limb, with much adduction, is more of a real deformity than one flexed at a much greater degree without adduction. In the former case the real shortening (I mean by that, the distance that the tilting upwards of the pelvis raises the foot from the ground in walking) is often more than double the real difference in length of the two limbs measured from the anterior superior spine. The object of performing an osteotomy here is, first, to correct any adduction of the limb that may exist; and, secondly, to reduce the amount of flexion to an angle of about 125°.

There are three points at which section has been made for the correction of deformities at the hip-joint, namely, through the neck, between the trochanters, and below the trochanter minor. The section through the neck, known as Adams's operation, can only be performed when the neck is present. It is, therefore, only applicable in cases of bony ankylosis following rheumatism; and it has been advocated in those cases of recovery from hip-joint disease, with bony ankylosis, in which there has been but slight destruction of the head. But it is a serious question whether cases of deformity after suppurative coxalgia should ever be submitted to this operation. In the vast majority of cases, the section would be made through bone infiltrated with inflammatory products of low vitality. The incision to gain access to the neck would frequently have to be made through tissues that had been the seat of abscess, and, even if this succeeded, after section it would be difficult to bring the limb down into a desirable position. It is not applicable to cases in which the psoas and iliacus are much shortened, and this condition is found after coxalgia more frequently than after any other disease. Again, the muscles inserted into the trochanter minor being still attached to the lower fragment, must tend to draw the limb inwards.

In regard to operations between the trochanters, the section is made further from the seat of disease in cases of deformity following suppurative coxalgia. It also permits of the removal of a wedge-shaped piece of bone, which is so desirable in cases of marked adduction; yet the point of division is above the insertion of the psoas and iliacus, and the same objections hold good as to Adams's operation. If the object is to obtain motion in addition to the correction of the deformity, there is no question that the nearer the division is made to the true axis of motion the better; but useful motion is seldom attained, no matter where the section is made, nor the method of making it.

Section below the trochanter, I think, will prove the best operation in the vast majority of cases in that it is below the insertion of the muscles attached to the trochanter minor; it is further away from the seat of disease in deformities following coxalgia; there is less danger of displacement inwards of the lower fragment. I think that the advantage of making the section below the smaller trochanter is not clearly understood. I have lately had the opportunity to examine the parts removed from two cases following an osteotomy for deformity at the hip-joint. In one case, the femur was divided between the trochanters; in the other, the line of section was oblique, from without inwards and downwards, so as to pass through the middle of the trochanter minor. In the first case, recovery had taken place with marked adduction; in the second there is a displacement inwards of the lower fragment that may be attributed, in part, I think, to the action of the psoas and iliacus, whose attachment had not been entirely freed. After section, extension was applied to the limb, by which the lower portion was brought down. The muscles inserted into the trochanter minor draw the upper portion of the lower fragment inwards, and cause a projection in this location.

In the first case the adduction may have been due to the same cause, although the adductors must have had considerable influence in drawing the limb towards the median line. In regard to the removal of a V-shaped piece of bone, as advocated by Volkmann, from between the trochanters when there is marked adduction, I do not think that it has any advantage over a simple linear osteotomy. It is true that if the size of the wedge has been accurately calculated, in connecting, the two sides of this V-shaped gap will come into apposition, while after a linear section there will be a gap left on the inner aspect of the bone, which will have to be filled up with new bone. Theoretically a cuneiform osteotomy is more liable to be followed by suppuration, but practically, if the wound is properly cared for, this accident should not happen. There is, however, greater danger of a piece of cellular or other tissue being caught between the fragments, after a cuneiform than after a linear section, and causing suppuration; and the former takes more time to perform. I am, therefore,

of the opinion that a linear section is much the better. The more simple an operation is, the better will be its results.

All efforts to obtain useful motion at the point of section have ultimately failed. In a few cases a movable articulation has been obtained, but in time all motion has been lost. In one case (Burton's), it lasted six years; and in another (Sands's), there was limited motion for two years. In other cases it has only lasted for a few months, notwithstanding persistent efforts to prevent consolidation. It would seem that the difficulties attending the formation of a false joint are great, and even if one is obtained, it is a question whether it is of any real advantage to the patient. I think that a stiff limb in a good position will afford the patient more security and easier locomotion than the best false joint in this situation, and that a false point of motion is more of a hinderance than an aid to walking.

The method of performing an osteotomy at the upper end of the femur does not differ from sections of bone in other localities. I see no advantage in a cuneiform section over a linear osteotomy, and I think that a division of the femur below the trochanter minor is a better operation, and will yield better results in the vast majority of cases than one above this point. The method I have adopted is to make an incision about one inch long down upon the outer aspect of the shaft of the femur, at a point just below the trochanter minor; then, upon the knife as a guide, pass an osteotome down, and divide the bone at *right angles* to its long axis. After the bone has been nearly divided, the osteotome is withdrawn, and the section completed by fracturing the remaining portion. Some surgeons divide the tendons of the adductors and long head of the biceps and a portion of the tensor vaginæ femoris, and twist the bone in various directions, in order to break down any adhesions that may exist and stretch the muscles holding the femur in its abnormal position. Unless the deformity is very marked, I do not think a tenotomy is called for, and I have abandoned all twisting and manipulation of the shaft. After placing a narrow strip of adhesive plaster over the wound, so as to bring its lips into close apposition, but leaving a space on either side of the plaster uncovered, so that any undue accumulation of blood can escape, the parts are dusted over with iodoform, and a small compress placed over the wound and held in position by another piece of adhesive plaster. A bandage is then lightly applied, and a long splint, extending from the axilla to just above the external malleolus, no attempt being made to correct the abduction or flexion. An extension, with six or eight pounds weight, is applied after the patient has been put into bed. It will generally be found that upon the third day the wound has closed, when the extension is run up to ten or fifteen pounds, according to the age of the patient. This amount of extension will bring the limb down; and in all the cases that I have tried, it lowered the pelvis of that side, so that the limb is slightly abducted.

After an osteotomy in this locality, the patient should not be allowed to sit up in bed, but should be kept as flat as possible on his back, until firm union between the fragments has been established. A plaster-of-Paris splint is not a good dressing after this operation; it does not fix the pelvis well, it soon becomes loose and admits of motion; it does not permit of the use of an extending apparatus, and there is no opportunity to correct any malposition.

The great leverage exerted by the limb below the point of division, and the narrow space above this point over which the bandage can be applied, make it impossible to obtain fixation and control over the lower fragment, so that much of the good position gained in the operating-room is lost from the ability of the patient to flex and adduct the limb to a certain extent. A plaster-of-Paris splint is a good dressing when the limb can be encased some distance above and below the point of fracture; but when the splint only passes a short distance above this point, deformity will occur. The same holds true, but with much greater force, after an osteotomy in the upper part of the femur to correct a deformity in which there is muscular resistance continually to be overcome.

From a careful examination of the two specimens (Drs. Wharton's and Moore's), it is evident that the section has not been made at right angles to the long axis of the limb, although both operators supposed that the section was made transverse. This was due, I think, to the fact that the limbs were adducted, and the bone was divided at right angles to the body rather than at right angles to the femur. I am satisfied that I have made this mistake, and I think it a point one is apt to overlook, not taking sufficient account of the amount of adduction.

From the form of the femur at its upper portion, where osteotomies are usually performed, its lateral diameter being greater than its antero-posterior, there must, in all cases in which there is any rotation inwards of the limb, after correction, be a projection outwards of the inner portion of the lower fragment, because a wider portion of the femur is brought into apposition with a narrower.

The accidents following an osteotomy at the upper end of the femur are few—out of 148 cases, 119 were cured with the limb in a good position, 17 died, and there were 12 failures, making a mortality of 11.48 per cent. In thirty-three cases suppuration is reported, and in only three is any necrosis mentioned. In three patients an Adams's operation did not correct, or the deformity returned, and a section below the trochanter minor was performed with success.

In one case (Post), compression of the femoral vessels, from tilting upwards of the upper fragment, after a section below the trochanter, occurred, and in one severe hemorrhage came on on the twentieth day after a section through the neck (Servias), from either the femoral or one of its large branches, necessitating a ligation of the femoral. The patient recovered.

Maisonneuve is reported to have divided the sciatic nerve during an operation of section between the trochanters through a large wound.

The percentage of fatal cases mentioned above gives a higher rate of mortality than belongs to the

operation as now performed. Many of the operations were performed before experience had demonstrated what class of cases were proper ones for section. In some cases the section was made too high, or the patients were subjected to an operation at too early a date after the disease causing the deformity had subsided. Many of the operations were performed through large wounds, and extensive dissections were made to reach the bone. It is also found that twelve of the fatal cases occurred prior to 1877, and only five after that date, the number of cases being nearly the same in the two periods. Lately, Dr. E. M. Moore, of Rochester, has published a case in which he had performed an osteotomy between the trochanter for dislocation of the head of the bone. It was at first displaced on to the dorsum of the ilium, but by manipulation had been thrown above the superior lip of the acetabulum, the trochanter being turned backward. Section was made between the trochanters, and, after bringing the foot into its normal position, an extending weight of fifteen pounds was applied. The result was that the shortening, which before the operation had been two and a half inches, was reduced to one, new bone being deposited between the fragments one and a half inch in length. In one case I have tried to obtain a lengthening, and have succeeded.

MEDICAL PROGRESS.

SIR HENRY THOMPSON'S RECENT IMPROVEMENT IN THE ASPIRATOR FOR LITHOTRITY.—Last autumn SIR HENRY THOMPSON made an addition to his aspirator, which appears to be useful. It consist in a light, loosely hanging valve of fine wire, attached by a simple hinge to the end of the evacuating-tube, which terminates within the glass trap of the instrument. When pressure is made on the India-rubber globe, and the current flows by the evacuating-catheter into the bladder, this light valve is driven close to the aperture, and no débris can leave the glass trap. When the pressure is removed, and the current returns from the bladder, the valve floats widely open, and permits the débris to enter unchecked. The wire-valve is circular in form, and its border being flat and thin, and about the tenth of an inch wide, is delicately sensitive to the movements of the current, and responds to the slightest impulse of the hand on the India-rubber globe. But he is quite satisfied that with his last published aspirator, as well as with the form now described, no débris returns to the bladder if the instrument is properly used, when, of course, the valve is unnecessary. Few persons are aware that very slight but quickly made pressure on the globe, sufficing to transmit only six or eight drachms of fluid into the bladder, generally removes more débris than a powerful impulse which transmits at one act all the fluid contents of the globe, or nearly so. When employed in the manner last-named, the valve becomes useful, and only then is it required.

As to the present instrument itself, the form is simple; not far removed from the original pattern of Clover, but with the useful addition of a funnel and stopcock at the upper part of the globe, to facilitate the act of filling with water, as well as the escape of air. Moreover, the glass trap is easily disengaged from the globe, by which means the valve, which is sometimes liable to be partially blocked, as when much mucus and fine débris are present, can be easily cleaned. At the same time, this blocking of the wire grating of the valve in no way interferes with its competency in action. It is necessary that the end of the evacuating-tube within the glass trap should have the angular form represented, so that the lower end of the valve, when undisturbed by the current, should not close the orifice, but hang at a considerable distance therefrom.—*Lancet*, April 12, 1884.

LAPAROTOMY FOR INTERNAL STRANGULATION; RESECTION OF THE INTESTINE.—DR. D. MORISANI reports two cases of laparotomy for internal strangulation. One presented no particularly interesting features, but in the second case such extensive inflammation and adhesions were found that it was absolutely necessary to resect about three inches of intestine. The operation was performed by Gussenbauer's method, with the double Lembert suture. The patient died of shock.—*Rivista Internaz. di med. e Chir.*, March, 1884.

SYSTOLIC MURMUR AT THE APEX IN A CASE OF AORTIC LESION.—One of the elements of a cardiac murmur to which great importance is given is its seat of maximum intensity. When this is at the base of the heart, an aortic or a pulmonary lesion is diagnosticated; when at the apex, a mitral lesion; and between the apex and the epigastrium, a tricuspid lesion. All clinicians know that the seat of maximum intensity of the diastolic murmur of aortic insufficiency is sometimes heard below, along the left border of the sternum, and toward the xiphoid cartilage; but, so far, a systolic murmur heard only at the apex, and due to an aortic lesion, has never been reported.

The following case, reported by DR. WEILL, of Lyons, also seen by Prof. Lepine and several of the hospital physicians, is very interesting. P. P., æt. 47, entered the hospital on December 2, 1883, and died on the 27th. His health had been excellent until four years ago, when he had acute articular rheumatism. The trouble of which he died began five months before his entrance, with insomnia, oppression and palpitation, and œdema of the lower limbs. The apex beat was in the sixth interspace, outside of the nipple. The shock was perceived with difficulty. The beats were regular, and there was no fremitus. Auscultation showed a rude systolic murmur at the apex, short and blowing. It was audible over the sternum and base, and was propagated toward the axilla. It did not encroach upon the diastole or the presystole. There was no carotid murmur; the radial pulse was regular and sufficiently strong. The patient did not complain of precordial pain, and no sensitive spot could be found in the intercostal spaces. The area of cardiac dulness was not increased. There were a few pulmonary râles; the liver was enlarged; the urine albuminous; and the limbs showed a few purpuric spots.

At the autopsy, the examination of the mitral orifice and valves showed that they were absolutely sound. The left auriculo-ventricular orifice was not dilated, and the ventricular cavities, although enlarged, did not have a greater mean diameter than two inches. The aortic

orifice was sound, and about two and a half inches in circumference. The sigmoid valves presented, on their internal surface, near their free border, small fibrous nodules, arranged perpendicular to the axis of the vessels, having a length of from four-tenths to six-tenths of an inch, and a projection of from one-eighth to one-sixth of an inch.—*Revue de Médecine*, March, 1884.

PEPSIN AND THE PEPTONES IN THE TREATMENT OF DIABETES.—PROF. D. GIOVANNI (*Gazz. Med. Ital. Prov. Venete*, January 12, 1884) draws attention to the frequent utility of pepsin and peptones in the treatment of diabetes. He cites the following case. A young man, aged twenty, was admitted, and gradually submitted to an exclusively meat diet and lactic acid. Even when all milk, starchy, and saccharine matter were entirely omitted, the urine was as abundant as before, and the quantity of sugar the same, and the patient did not become stronger. The thought occurred to Dr. Giovanni that all the meat and eggs taken were not utilized in the organism. The bodily strength was not in proportion to the force of the foods, neither was the quantity of urea in the urine. The examination of the feces showed a large quantity of meat, unaltered and scarcely masticated. The patient was then placed on ordinary diet, but with a certain quantity of pepsin and peptones, prepared according to the method of Prof. Lussana. (The stomach of a calf is cut in pieces, and placed in a quart of dry white wine; after eight days filtered; the filtrate contains pepsin and peptones.) The patient quickly began to improve in general nutrition, and was able to get up; the quantity of sugar and of urine was lessened. On returning to the meat-diet the patient again became worse, and was again better on the substitution of the mixed diet, with pepsin and peptones. Continuing this diet, he so far recovered as to be able to leave the hospital, and a year afterwards, though diabetic still, was in fair health. Professor Giovanni has found equal benefit in other cases from the same treatment, but not in all. He concludes that pepsin and the peptones (Lussana) constitute an element useful in completing the diet of the diabetic, when defective gastric function helps to exaggerate the effects of the disease on the general health.—*London Medical Record*, March, 1884.

WASHING OUT THE STOMACH.—DR. A. BIANCHI, in a paper read before the Academia Medico-Fisica of Florence, reports that he has had excellent results, both palliative and curative, in the treatment of cases of cancer of the stomach, chronic gastric catarrh, chronic gastritis, gastric ulcer, gastric catarrh with chronic hepatitis, digestive disturbances from slight gastritis, and dilatation of the stomach, with slight catarrh and insomnia, by means of the Débove method.—*Gazz. degli Ospitali*, March 26, 1884.

THE TREATMENT OF PERINEAL INJURIES OF THE URETHRA.—DR. C. KAUFMAN, after a general consideration of this subject, draws the following conclusions:

1. In all cases in which catheterization is difficult, or not very practicable, the perineum should be incised, cleaned out, and disinfected. In small, transverse wounds, spontaneous union should be attempted; in complete rupture of the urethra, sutures should be employed, so as exactly to approximate the edges. The catheter should only be used during the first few days, and should never be left in the urethra.

2. Treatment with the permanent catheter should be entirely abandoned. Whenever a sign of inflammation appears, the perineum should be incised.

3. Cystotomy, as a method of treatment, should be given up, and only be used in cases of retention.—*Centralbl. gesammt. Therap.*, March, 1884.

A NEW SPONGE.—MR. SAMPSON GAMGEE, after a number of experiments with a variety of materials, with a view to preparing a sponge combining absorbing power and elasticity, and cheap enough to be burned after use, has found that a ball of curled cocoanut fibres, enclosed in absorbent gauze, sinks in water. That established, he made other balls with absorbent cotton in the centre of the cocoanut, absorbent cotton round it, and then the gauze envelope, the idea being to take up the fluid rapidly, and transmit it, through the springy cocoanut fibre, to the absorbent-cotton centre. He found that a ball so made takes up most readily from sixteen to eighteen times its own weight of blood or water, which, when squeezed out, still leaves the ball elastic and absorbent, readily filling and swelling out again, when dipped in liquid and squeezed, a number of times in succession. Having secured a good combination of fibres, it became a question how to render them perfectly and permanently antiseptic. Mr. Gamgee thought that within the absorbent-cotton nucleus of the sponge might be enclosed a very thin ball or capsule; containing the antiseptic, of any kind, and, within certain limits, in any quantity desired; the antiseptic to be set free by cracking the capsule with a squeeze, just before using the sponge. The idea proves perfectly practicable, and Messrs. Burroughs, Wellcome & Co., the manufacturing chemists, have undertaken to carry it out. A small capsule, containing eucalyptus, or other antiseptic, is inclosed in absorbent cotton, outside this is a layer of cocoanut fibre, and outside this more absorbent cotton-wool, the whole being inclosed in gauze. When about to be used, the capsule can be broken by a blow of the fist, and the absorbent cotton then becomes permeated with the antiseptic. The sponges can be manufactured at a very trifling cost—about a shilling a dozen—and being so cheap they can be destroyed after being used. Some little time must elapse before all the details can be perfected, but sufficient evidence has so far been obtained to warrant the belief that the principle of this sponge may be adapted to the fulfilment of many requirements, as an absorbent and antiseptic sponge, pad, or dressing, in civil or military surgery, in medical and in obstetric practice.—*Brit. Med. Journ.*, April 26, and *Lancet*, May 3, 1884.

RUPTURE OF THE RIGHT COMMON ILIAC AND OF THE INFERIOR VENA CAVA.—M. CERNÉ reports the case of a woman who was run over by a vehicle. One of the wheels passed over the abdomen, and she expired in a few minutes. Post-mortem examination showed a rupture of the right common iliac artery at its origin, and of the inferior vena cava. The artery was very atheromatous.—*Journ. de Méd. de Paris*, March 29, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 7, 1884.

IDIOPATHIC PERITONITIS.

THE latest candidate for a place among the infectious diseases, with a microparasite for its cause, is idiopathic suppurative peritonitis. In a recent paper in the *Deutsche med. Wochenschrift*, for April 24, E. LEYDEN, after collating a large number of facts from German, French, English, and American literature to prove the existence of idiopathic peritonitis, which has sometimes been questioned—asserts also its parasitic origin. He also reports three cases from his own experience, of which two died and one recovered; but he does not claim to have discovered a distinct parasite, with definite anatomical characters, as he has noted several apparently distinct forms. Idiopathic suppurative pleurisy, he believes, has a similar origin.

In the freshly removed purulent exudate of malignant puerperal peritonitis he also found numerous cocci of invariably the same shape and color; and as the puerperal cases were throughout their entire course more malignant and accompanied by more profound general symptoms, so the micrococci were found to be much more intensely active, infiltrating the muscular substance of the diaphragm, and extending even to its pleural surface, where, too, they had excited inflammation. All of these purulent peritoneal exudates were odorless, and could not be regarded as septic, while the general symptoms to which they gave rise could not be regarded as those of septicæmia. The putrid exudates, of which Leyden also investigated several, distinguished themselves essentially from the simple in that no pure cultures of the microparasite could be obtained from them, but mixed forms, in which especially occurred, along with diplococci bacilli, which partly arranged themselves in long threads and chains. The same was true of putrid pleural exudates.

From such cases, Leyden also eliminates rheumatic peritonitis, including certain instances of acute peritonitis accompanying acute articular rheumatism, in which the exudate is not purulent, but serous.

These causative agents of idiopathic peritonitis enter the system as in other infectious diseases. Such causes as indigestion, constipation, and injury may furnish the conditions favorable to the germs of the disease establishing themselves in the peritoneum. In the female, menstruation especially may coöperate with such causes. During this condition there is a breach of continuity in the uterine mucous membrane attended with a prolonged hemorrhage, so that circumstances favorable to the fixation of the parasite are presented. A further favorable condition is the communication between the uterus, through the Fallopian tube, and the abdominal cavity.

In the matter of treatment of idiopathic peritonitis, Leyden suggests a measure which, although undoubtedly not novel, has nevertheless been so seldom practised, that notwithstanding its apparently unpromising character, it may reasonably claim further consideration from physicians and surgeons, especially in the light of the recent enlargement of the field of abdominal surgery. It is that of evacuation of the purulent contents of the abdomen by paracentesis. He supports this suggestion by his experience with a case in which a splenic abscess, bursting into the abdominal cavity, produced a fatal peritonitis, which, he thinks, might have been averted had the abscess been evacuated. This may be true, but we scarcely think a conclusion as to the treatment of idiopathic peritonitis dare be drawn from such a case any more than from the effects of rupture of an abscess of the liver. Neither case is one of idiopathic inflammation, and death probably resulted from collapse before any inflammatory action could be excited. Again, the accumulation of pus in peritonitis is never so large as in pleurisy, and the consequent difficulty in making an accurate diagnosis, as well as the danger of wounding the subjacent distended bowel, make it unlikely that the operation of tapping the abdomen can ever be rendered available in practice. A much better treatment would be laparotomy, irrigation with sublimate solutions, and drainage.

PULSATION OF THE LIVER AND TRICUSPID REGURGITATION.

THAT the true pulsating liver is the result of regurgitation of blood from the right ventricle into the corresponding auricle and thence into the descending cava, is as generally conceded as that pulsation of the jugulars is due to the same cause. But few

pause to consider the mechanism of this sign. That the blood thus regurgitated should produce a pulsation in the valveless jugulars, which come off close to the auricle, is not so remarkable, but that an organ so distant as the liver should receive an expansile impulse from the same cause is less plain. DR. WALTER SMITH discusses this subject in the report of a case in the *Dublin Journal* for January.

One other cause for the sign has been suggested, and that is a direct shock communicated from the heart coincidently with the impulse. But the liver pulsation continues after the ventricles have ceased to contract, while when the condition of the patient improves the pulsation becomes less; whereas if due to direct shock the contrary should be the case, because the steadier and more forcible action of the heart would increase the pulsation.

In a word, it may be said that the effect of the regurgitant wave, which, of course, exerts itself to a certain degree throughout the entire circulation, is more easily rendered appreciable in the liver on account of anatomical peculiarities rendered necessary in order to secure a proper movement of the blood through the portal vein. It is apparent that there is very little *vis a tergo* to this blood, which is largely collected from the gastric and intestinal capillaries. Hence there would be little or nothing gained by furnishing its trunk or its branches with the elastic coat which forms so important a part of the structure of the arteries; for the power of this depends upon a *vis a tergo*, which is necessary to secure the elastic recoil. At the same time, the vena portæ has to perform the duties of an artery, and some additional means of propelling the blood must be secured.

This is effected by favoring the operation of the force of respiration — a generally admitted, though feebly acting factor — upon the movement of the blood throughout the veins. In the act of inspiration the entire cubic capacity of the thorax is increased, and all the hollow organs contained in it, of which the heart is one, tend to fill up with the fluid accesssible to them. Now, the operation of this agency upon the liver is favored by the fact that the trunks of the hepatic veins almost pierce the tendon of the diaphragm to join the inferior vena cava; these veins cannot collapse when subjected to atmospheric pressure, *i. e.*, to the aspiratory action of the mediastinum, or the suction power of the heart, because they are tunnelled out in the substance of the liver—are, in fact, comparatively rigid tubes, unsurrounded by loose connective tissue. In inspiration, by the contraction and descent of the diaphragm, the caval orifice of the hepatic vein is stretched, the vena cava itself straightened, and the course and openings of the hepatic veins made more direct. During the act of expiration, on the other hand, all these conditions are reversed, and at the very time the intra-thoracic space is lessening and the blood has a tendency to regurgitate into the hepatic veins, this tendency is counteracted.

Now, if regurgitation of blood from the right heart takes place, this very condition of patulous sinuses, approximating rigid tubes, favors the communication to the liver of any pulsation caused by reflux into the inferior cava and larger hepatic veins. But before hepatic pulsation can occur, the impulse must be strong enough to overcome the suction power of the heart in inspiration, the resistance of the parenchyma of the liver, and the elasticity of the liver's capsule, as well as the conditions named as tending to prevent regurgitation during ordinary expiration. Hence, inflammatory thickening of the capsule, by which its elasticity is destroyed, tends to prevent hepatic pulsation. The elasticity of the capsule is a further conserving force in preventing undue compression of the substance of the liver between the blood in the over-distended hepatic vessels and the capsule itself.

ANTE-NATAL INFLUENCES.

THERE is hardly any subject of greater interest, and in regard to which so little is known, as that of ante-natal influence, whether at the time of conception, or in the subsequent development of the new being. Speculations are many; dreams and dreamers, fictions and fancies are numerous, but our real knowledge is very little more than that which was possessed many centuries ago. Diogenes said to the stupid youth: "Your father was very drunk when you were conceived." Vulcan's deformity was the proof of Jupiter's drunkenness when he was begotten. Modern science has shown that if a fruitful coition occurs when either of the parties is drunk, the child usually has some physical, intellectual, or moral defect—epileptics and imbeciles may thus be created. This is about the limit of our certain knowledge.

But with this fact proved, it is in the highest degree probable that less pronounced, less easily discovered and appreciable intellectual and physical conditions of the creators at the time of creation may, and do impress themselves upon the offspring. The swift and subtle power by which the sunlight clearly and indelibly reproduces on dead matter the exact image of form, features, and expression, may be but the type of the impressing the intellectual, moral, and physical character upon living matter at the time of the creation of a new being, and the qualities and characters that are shown in the months and years that follow are but the working out of those first forces in organization.

Considering the fact that most children are accidents, we have no reason for surprise at examples of physical deformity or imperfection, mental deficiencies, or moral obliquities, but rather that the average is so good. When human beings invest the possi-

bilities of reproduction with its true and vast responsibilities, with its far-reaching consequences, there will be a great improvement in offspring. Man or woman prepares for the photographer by a careful toilet, strives to go unfatigued, and with a face undarkened by sorrow or anxiety—in a word, is desirous, if not from personal vanity, at least with the wish to please others, of appearing at his or her best in the counterfeit presentment which is made. Ought not much more care to be exercised by parents in the possible reproduction of themselves, of themselves as they are at that special time? A child is the incarnation of the qualities, good or bad, of the parents, and possibly it may be the incarnation of transitory states, temporary impulses, feelings, or thoughts—noble or base, cheerful or sad, healthy or morbid—of those parents. A few minutes may determine whether these living images shall be happy, helpful, useful members of society, and a blessing to their homes, or born to a heritage of disordered, diseased nature, darkening their own lives and those of others, until death is a blessed relief.

As to subsequent influences exerted through the pregnant woman's mind upon her unborn child, we are in the region of fable and conjecture; most extraordinary stories have been told of the effects of some horrible sight which suddenly startles the mother, and, through her, affects the fœtus. Van Swieten states that he saw a young lady who had upon her neck the exact representation of a caterpillar, as "closely resembling it as two eggs resemble," and the cause was that the mother when pregnant was frightened by finding a caterpillar upon her neck. Quite in contrast is the alleged influence of a continuous impression. Haller, a man not less remarkable for his learning than for his truthfulness—at least he never made a statement that he did not believe—assures us that an Ethiopian woman had several white children, and the explanation was that she had in her house a white marble statue. The physician to-day would give a more plausible cause of such color anomalies. A recent writer has attributed the kleptomania of a wealthy lady to the fact that when pregnant her mother was denied the "cravings for a variety of things" by the stinginess of her husband. Again, a child has been born with harelip whose mother attributes the deformity to her having seen when two or three months pregnant, or later, a child or adult with similar deformity; the physician knows that such arrest of development must have occurred before the earlier of those periods. It is, in part, because of such extravagant and unreasonable stories that the great mass of physicians reject the theory of mental impressions made upon the mother in pregnancy affecting the fœtus. Another reason for this general rejection is our inability to explain how such impressions can act upon the fœtus. But it would be more scientific to find out whether they do, and afterward seek the mode; before deciding the impossibility of a fact occurring, let us first look for the facts, and then seek their explanation. Here is an important field for inquiry, for the collection of well-authenticated facts; after this collection we may determine their meaning, make their interpretation. That the fœtus may be affected by impressions made upon the mother's mind, has long been and still is commonly believed. A popular belief so widespread and so long-lasting indicates in these very conditions the probability of its containing some element of truth.

We have been led to these reflections by reading the report of a lecture recently given by M. LEGRAND DU SAULLE, at Salpêtrière, in which he refers to the "infants of the Siege." He states that the numerous disorders of development and the exceptional mortality observed in children born in the latter months of 1871, caused them to be known among the laboring population as *enfants du Siège*. Inquiry proved that of 92 children conceived during the siege, 64 had physical, intellectual, or affective anomalies, and 28 others were small and sickly; 21 of the 64 suffered as to the intellect—dull, imbeciles, or idiots. M. Legrand du Saulle, regards "the pathogeny as complex, its chief elements being alcoholism, inanition, and the psychical state determined by the moral shock in circumstances especially dramatic."

IN another column we are told of the substantial recognition by Germany of the great service done to medicine and to humanity by the illustrious Koch in his recent discoveries, and by Frerichs in his contributions to the advancement of medical science. This week the Philadelphia profession has testified its grateful appreciation of the life and work of one of the noblest and most distinguished of American physicians, Dr. Alfred Stillé.

This spontaneous and hearty recognition of the great service Dr. Stillé has rendered to medicine in his many years of active labor is at once just to him and honorable to the profession. It does immediate good, enlarging the hearts of participants, and raising men into a purer atmosphere than that which is found in the strifes and struggles of daily life. It does remote good, for it invites young, ambitious men to walk in the footsteps of him thus honored, to live his pure, industrious, and useful life, and it assures them that they will find in such living its highest reward, and that professional recognition of the best will not fail.

It is given to but few men to be discoverers in any department of medicine; but industry, fidelity, high and noble purpose, and philanthropic work are in the power of many, and all who use their power wisely will surely find their reward.

SOCIETY PROCEEDINGS.

THE ILLINOIS STATE MEDICAL SOCIETY.

Thirty-fourth Annual Meeting, held at Chicago, May 20, 21, and 22, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, MAY 20TH—FIRST DAY.

THE Society was called to order, at 10 o'clock, by THE PRESIDENT, EDMUND ANDREWS, M.D. He then introduced DR. EPHRAIM INGALS, who, on behalf of the Committee of Arrangements, made a brief address of welcome.

THE PRESIDENT, DR. EDMUND ANDREWS, then delivered

THE ANNUAL ADDRESS.

There is much talk, at present, he said, upon the Ethical Codes of the American Medical Profession. It is necessary to go slowly. It is necessary to recognize, as governing the profession, a code of ethics and a code of etiquette. The laws of ethics or morals are unalterable, eternal, natural laws, and back of them stand God; they were not created by the American Medical Profession—as many believe. Ethical laws, written or unwritten, demand of the physician the greatest possible knowledge of disease, its application for the benefit of his patients, kindness, courtesy and geniality to those under his care and to his professional brethren. Laws of etiquette require adherence to certain, well-recognized conventional forms—which are of importance, but are artificial and always subordinate to the demands of ethics.

A few years ago, doctors galloping along in the country were like so many brutal centaurs, cantering over corduroy roads, snorting defiance at each other, and stamping beneath their hoofs all principles of ethics and etiquette. To remedy this evil, the Code of Ethics came into existence. Certain centaurs resisted subjugation. At the present time the tendency is to carry matters to the opposite extreme and thrust professional conduct into rigid forms of plaster-bandage inflexibility. As the result of this over-refinement, a new species of the medical man, "the medical dude," has come into existence. "Let the centaurs and the dudes fight over the code! What we want is not so much a better form of ethics as a better knowledge of the great principles underlying all codes."

DR. J. F. TODD, of Chicago, on behalf of the Committee on Registration, reported that one hundred and twenty-six delegates had registered.

The Report of the Committee on Practical Medicine, DR. J. C. FRYE, of Peoria, Chairman, was presented, and was a faithful effort at sketching the progress made in practical medicine during the past year.

AFTERNOON SESSION.

DR. PRINCE, of Jacksonville, on motion, was permitted to present a voluntary paper upon

CLOSURE OF THE SOFT AND HARD PALATE,

and exhibited a lad upon whom he had recently operated, with more than usual success, both as regards union and recovery of function. The case was one of single cleft of hard and soft palate, without harelip.

The Report of the Committee on Surgery, DR. ROSWELL PARK, Chairman, gave a very brief summary of progress in surgery during the past year.

DR. DAVID S. BOOTH, of Sparta, presented a well-considered paper on *Sponge Grafting*. This method had been tried with excellent results in three cases.

DR. H. GRADLE, of CHICAGO, presented a paper upon

THE ETIOLOGY OF DISEASE,

in which he pointed out that the search for the causes of disease can best be systematized by making a sharp distinction between primary diseases and secondary disturbances. The former represent the direct reaction of living tissue to injurious influence of external origin, as seen in any infective disease or any injury, while the latter are dependent, not on any external cause, but on some preëxisting primary disease, primary lesion, or structural anomaly, somewhere in the body. As a type of a secondary disturbance, may be mentioned a cerebral embolism due to a plug derived from a diseased cardiac valve.

The only causes of primary disease known are (1) physical influence, for example, trauma, extremes of temperature, and electric currents; (2) chemical action, as poisons, or, in a negative way, the deprivation of indispensable food constituents; and (3) parasites.

In discussing the importance of parasites, both animal and vegetable, the writer showed what had hitherto been done in finding supports for the germ theory. He insisted that the parasitic origin of any disease can be accepted as proved only when the parasite has been found in every case examined during the active stage of the disease, and to an extent commensurate with the extent of the lesion, and when the disease has been reproduced by inoculation with isolated parasites. He stated it as singular that those who still oppose the germ theory on account of insufficient familiarity with the facts, have never demanded or suggested any better proofs of the parasitic origin of any disease than these mentioned. He then reviewed the work of the past year in tracing the bacteria of pneumonia, osteomyelitis, cholera, typhoid fever, diphtheria, and xerosis of the conjunctiva. He pointed out the value of Koch's work in tuberculosis, and the demonstration accomplished by him and others that scrofulous glands and lupus are but tubercular lesions.

While each primary disease, as far as it represents a single, uncomplicated disorder, has but one exciting cause, there may exist numerous predisposing conditions. These should not be called predisposing causes, for they cannot *cause* the disease; they can only favor its occurrence. The predisposing conditions comprise the conditions determining the mode of life and distribution of disease germs outside of the body and the influences interfering with the resistance of the body to the parasitic invasion. Under the former head the most important question is whether the germs of any given disease can vegetate outside of the body under the conditions existing in nature, or whether they are limited to a parasitic life in animals. The extent of our information on this point was discussed and the practical bearing illustrated by mentioning the detection of the cholera bacilli in an infected tank in India, and of the pneumonia micrococci in the filling of the floors in a prison in which the disease occurred as an epidemic. The

speaker then referred to the researches of some English physicists on the conditions determining the deposition of floating dust and their relation to the invasion of the body by germs.

In illustration of recent work having reference to predisposing conditions which made the body more prone to parasitic invasion, were mentioned the importance of minute lesions in erysipelatous and diphtheritic infection of indigestion in permitting the cholera bacilli to pass through the stomach where the acid otherwise kills them, and of desquamation of bronchial and pulmonary epithelium from measles in favoring the invasion of the lungs by the bacillus tuberculosis.

A striking instance was related of the spread of pulmonary tuberculosis amongst cattle in the vicinity of the smelting works at Freiburg, in Saxony, where the arsenical fumes emitted by the furnaces start a capillary bronchitis developing subsequently into phthisis on account of the favorable conditions for the vegetation of the tubercle bacilli. Reference was then made to mixed infections, recent researches having shown that the occasional atypical course of such diseases as typhoid fever and diphtheria, and probably many others, is due to secondary invasion of the body by other, in a certain sense accidental, bacteria. There exist also diseases, which, while they are primary in being parasitic invasions, are secondary in a certain sense, since they depend on the previous existence of the same kind of infection in another part of the body; for instance, gonorrhœal joint affections in which the gonorrhœal micrococci have been detected in the blood and the diseased joints. Secondary disturbances are due to the influence which a diseased part or structural anomaly may exert on distant organs through mechanical contiguity, through the vessels, or through the nerves. Amongst the new contributions to this subject were mentioned the instances of self-poisoning known as acetonaluria, or diabetic coma, which have been reported also in connection with other diseases than diabetes; furthermore, the effects of fibrin ferment liberated in consequence of blood extravasations. The various organs were then reviewed as starting-points of nervous disturbances. The intestinal canal is especially significant in this respect, mention being made of Bartholow's "enteric paraplegia." The reflexes, taking their origin from anomalies of the sexual system, from eye-strain, and from ear-diseases were also considered. Finally, the important work of Hack and some confirming observers was referred to, which has taught us that the surface of the cavernous plexus lining the inferior turbinated bone of the nose is very frequently the starting-point of important nervous symptoms and even slight structural changes, as œdema of the skin and serous effusions into muscles. These occurrences may explain many instances of that mysterious bug-bear "taking cold" as complicated reflex actions originating in irritation of the sensitive area in the nose.

DR. E. F. INGALS said that not only the structures covering the middle turbinated bone, but also those covering the inferior—particularly its posterior end—and the lower half of the septum, contained nervous elements, irritation of which gave origin to various forms of cough and asthma. Nine cases out of ten of hay asthma were due to irritation of these nerve fibrils. The indication in the treatment of these is to cauterize and destroy, by the galvano-caustic wire, all redundant tissue or isolated spots, as revealed by the probe.

DR. VAN HORN, of Jerseyville, thought Dr. Ingals's treatment heroic. The laudanum spray or inhalation had been effective in his hands in aborting hay asthma.

The Report of the Committee on Gynecology, DR. W. S. CALDWELL, of Freeport, Chairman, was presented, and referred to the Committee on Publication.

WEDNESDAY, MAY 21ST—SECOND DAY.

The Committee on Necrology presented a report, which was received and referred to the Committee on Publication.

THE SPECIAL COMMITTEE ON VACCINATION,

DR. M. F. BASSETT, of Quincy, Chairman, presented a report which concluded with a vehement protest against bovine virus, as slow and uncertain in action, and as productive of profound local and constitutional disturbances.

DR. S. H. LAMBERT, of Assumption, thought that the objections to bovine virus would be entirely removed if quills were employed, and the patient received from two to four grains of salicylic acid or sodium salicylate, three times daily, in case of fever.

DR. EPHRAIM INGALS obtained good results with both humanized and bovine virus. In females, the place of selection should be the leg, as a less beautiful member than the arm.

DR. COOK, of Mendota, preferred humanized virus.

DR. CLARK, of Chicago, used humanized virus. In his younger days he had employed bovine virus upon one occasion, and severe local disturbance arose, accompanied by a peculiarly offensive discharge, namely, the discharge of the doctor.

DR. A. B. STRONG, of Chicago, used bovine virus with excellent results.

DR. J. I. CORCORAN, of Brimfield, had been inoculated in his youth; there was danger of introducing syphilis in the use of humanized virus, and of causing serious local and constitutional disturbance by employment of the bovine material; he did not believe in vaccination at all. It was useless, unwarranted cruelty.

DR. JONES, of Danville, referred to his experience during the war, at Lebanon, Kentucky, as a protest against humanized virus.

DR. WALTER HAY, of Chicago, preferred bovine virus.

DR. H. A. JOHNSON, of Chicago, shortly after the fire, in his official capacity as physician to the Relief and Aid Society, received authentic records of forty thousand cases of vaccination, in which humanized virus was employed, with not one case of syphilis, and only five or six cases of sloughing or erysipelas as a result. When local troubles followed, it was highly probable the scratch of a pin would have produced the same effects. Of one hundred thousand immigrants, who were vaccinated and kept under observation from one to three weeks, uniformly good results were obtained with bovine virus. The method of propagation of bovine virus was usually faulty, and when this was the case, humanized virus was preferable.

Dr. C. H. Norred, of Lincoln; Dr. H. T. Gill, of Ohio; Dr. S. J. Jones, of Chicago; and Dr. Edmund Andrews were favorably disposed to bovine virus, believing, however, that in the operation of vaccination the condition of the patient's system was an important factor.

DR. CHRISTIAN FENGER, of Chicago, was then invited to read a voluntary paper on

EXCISION OF THE HIP AND KNEE-JOINT, WITH SPECIAL REFERENCE TO THE FINAL RESULT.

He said that Volkmann's indications for operation are four in number:

(1) Presence of abscess in joint, fistulous communication with air, evening rise of temperature, and emaciation. (2) Chronic cases, when high fever is developed from suppuration in joint. (3) Formation of iliac abscess, indicating acetabular perforation. (4) Suppuration established within the joint, accompanied by complete luxation of head of femur. Dr. Fenger adds a fifth indication. (5) Detachment of the epiphysis of the head of the femur.

The paper was well illustrated by the exhibition of three cases, in which excision had been resorted to at an early period. The pathological specimens taken from the cases and presented for examination elicited much interest.

AFTERNOON SESSION.

DR. H. A. JOHNSON, of Chicago, read a brief abstract of a paper upon

BILATERAL PARALYSIS OF THE POSTERIOR CRICO-ARYTENOID MUSCLES,

and exhibited the patient who was the subject of the paper. Three years ago, tracheotomy was performed by Dr. Andrews, and the case then passed into the hands of Dr. Morell Mackenzie and Dr. Lennox Browne. Letters from both these gentlemen were read.

The patient wears his tracheal tube with perfect comfort. As regards the causation of the paralysis, Drs. Johnson, Mackenzie, and Browne are very much in the dark, but regard fixation of the arytenoid cartilages as standing in that relation.

DR. E. F. INGALS related his own experience in connection with a case of paralysis of the abductors, due to carcinoma, in which tracheotomy had prolonged the patient's life.

DR. D. W. GRAHAM, of Chicago, presented a paper on *Tracheotomy in a Case of Asphyxia Resulting from Goitre*, with exhibition of patient.

The Committee on Diseases of Children, DR. J. P. MATTHEWS, of Carlinville, Chairman, presented a report, which was referred to the Committee on Publication.

The Committee on Physiology, DR. A. WETMORE, of Waterloo, Chairman, likewise presented a report, which was referred to the Committee on Publication.

THE COMMITTEE ON ORIGINAL INVESTIGATION,

DR. N. S. DAVIS, of Chicago, Chairman, reported progress, and asked continuation for another year, with the appointment of two additional members.

Dr. Davis said that it had been the object of the Committee to determine the meteorological and telluric conditions of three acute diseases, to wit: acute rheumatism, acute pneumonia, and diphtheria, by sending out circulars to practitioners throughout the State, and obtaining data from the Signal Service Stations, in the manner of the Collective Association of the British Medical Association. He was of the opinion that bacteria did not play an exclusive *rôle* in the causation of disease, and that facts derived by the method of investigation, would have a healthful sedative effect upon the germ-theory fever. Two hundred and fifty dollars had been devoted to these investigations, and was an amply sufficient sum.

DR. F. C. SHAEFER, of Chicago, then read a voluntary paper on *Fracture of the Humerus into the Bicipital Groove, with Splitting off of the Greater Tuberosity*, and exhibited a patient to whom this accident had occurred.

THURSDAY, MAY 22D—THIRD DAY.

The Committee on Legislation for the Insane, DR. WALTER HAY, of Chicago, Chairman, reported progress, and stated that at the next meeting of the State Legislature important results would be secured.

THE COMMITTEE ON AMENDMENTS TO THE ANATOMICAL LAW,

DR. A. B. STRONG, of Chicago, Chairman, reported that there had been great difficulty in obtaining dissecting material during the past year in Chicago, due to the fact that the Board of County Commissioners refused to deliver up the pauper dead, on the ground that the law was *not mandatory*. There was abundance of material, but the Commissioners demanded such an exorbitant price that it was cheaper to go to other markets.

An amendment, making the law of delivering up the pauper dead to physicians in city and county, for scientific purposes, mandatory, had been drawn up, and a copy had been mailed to every one of the five thousand practitioners of medicine in the State of Illinois. Each copy of the amendment was accompanied by a letter requesting each practitioner to use his influence with his Representative in the Legislature.

DR. J. F. TODD, on behalf of the

COMMITTEE ON REGISTRATION,

reported the presence of one hundred and forty-four regular delegates.

The following were then elected

OFFICERS FOR THE ENSUING YEAR

on the recommendation of the Committee on Nominations:

President.—Dr. David S. Booth, of Sparta.

Vice-Presidents.—Drs. S. C. Plummer, of Rock Island; W. T. Kirk, of Atlanta.

Secretary.—Dr. S. J. Jones, of Chicago.

Treasurer.—Dr. Walter Hay, of Chicago.

Assistant Secretary.—Dr. H. B. Buck, of Springfield.

Members of the Judicial Council.—Drs. S. K. Crawford, of Monmouth; G. W. Jones, of Danville; John Wright, of Springfield.

Committee of Arrangements.—Drs. Griffith, Mathews, Rauch, Whitney, and Buck, all of Springfield.

Place of meeting, Springfield.

DR. CHRISTIAN FENGER then read an abstract of a paper on

SURGICAL TREATMENT OF GANGRENE OF THE LUNG.

Four operations for gangrene of the lung had been performed up to date. The *first* was performed in 1879, by Lawson and Cayley, London, for gangrene of five weeks' standing (Medical Society of London, 1880). The cough was lessened, dyspnœa and fetor diminished. Patient died on fourth day after operation. From the

autopsy it was concluded that if the operation had been performed earlier the chances for a favorable termination would have been greater. The *second* operation was performed by Solomon Charles Smith, in Halifax, 1880, for acute gangrene, occurring in the lower lobe of left lung, in the second week of croupous pneumonia. Cough was rendered less aggravating, dyspnœa and fetor decidedly influenced for the better. Patient died on the tenth day. No autopsy. The *third* operation was performed by Buhl, of Christiana, Sweden, in 1880, for acute gangrene. The anterior portion of left lung was removed. Patient recovered after six weeks' convalescence. The *fourth* case occurred in the practice of Christian Fenger, Chicago. The patient, male, thirty-four years old, was in the latter part of second week of croupous pneumonia. The lung was in the stage of resolution. There were much pain, distressing cough, expectoration of one pint of sputa in twenty-four hours, progressive loss of strength and appetite. The fetid breath of the patient was intolerable. Percussion gave dulness in right infra-mammary region, extending into right axilla. Auscultation revealed signs of cavity corresponding to this area. Cavity was found by insertion of the needle of a hypodermatic syringe. An incision was made parallel to right clavicle, portions of the ribs removed, the needle inserted into the cavity as a guide, the cavity opened by the small platinum point of a Paquelin's thermo-cautery, to sufficient extent to admit the index finger. No loose necrotic tissue being found, the cavity was washed out and antiseptic dressing applied. Subsequently, bits of necrosed lung tissue were discharged through the thoracic opening. Irrigation of the cavity invariably brought on violent spells of coughing. Hemorrhage was trifling. Five hours later the fetor had diminished perceptibly. The patient improved steadily, and at time of presentation of the paper, five weeks after the operation, was sitting up half the day.

As regards the *technique* of the operation, the writer called attention to the line of incision; it should be parallel to the clavicle, or ribs. One or more ribs must be excised throughout a sufficient extent. It is necessary to use the needle of a hypodermatic syringe as a guide. With the Paquelin, hemorrhage is inconsiderable. The cavity should be washed out if practicable. Care must be exercised in this procedure, as there is danger of drowning the patient if the cavity communicates with a bronchus.

Buhl observed no irritating cough as the result of irrigation of the cavity. Mosler, however, had seen the same result as that noted in the writer's case, namely, very irritating cough consequent upon the irrigation. Mosler ascribed death to the use of a weak solution of thymol. Turpentine inhalations were regarded as superfluous, if not positively injurious. After-treatment must be conducted on well-recognized surgical principles.

DR. THAYER then offered the following conclusion: Surgical interference in acute, circumscribed pulmonary gangrene is indicated; there is no immediate danger of the patient's death if the operation is properly performed.

The Committee on Obstetrics, DR. S. K. CRAWFORD, of Monmouth, Chairman, presented a report, which was referred to the Committee on Publication.

DR. R. H. BABCOCK, of Chicago, then presented an interesting case of

DEXIO-CARDIA,

occurring in a boy, three years old. The heart was shown to lie entirely to the right of the left edge of the sternum, the apex beating below the right nipple. The organ was so hypertrophied as to cause prominence of the costal cartilages of that side. It was not congenital, since the abdominal viscera were not transposed, as—according to Schrötter—is always the case in congenital dexio-cardia. The history was obscure, but the author concluded, from the present condition of the right lung, that it was the result of pleuritic adhesions. There was undoubtedly mitral lesion, as there was a systolic and diastolic murmur, partaking of the character termed by the French, *bruit de galop*. In conclusion, the Doctor referred to a similar, though more complicated, case, occurring in a man thirty-two years of age, which he has had under observation since last January.

Opportunity was subsequently given the members of the Society to examine the boy.

AFTERNOON SESSION.

REPORTS

from the Committees on Gynecology, Ophthalmology, and Otology, and on Drugs and Medicines, were received, and referred to the Committee on Publication.

THE TREASURER'S REPORT.

DR. WALTER HAY reported the receipts during the last year, with the balance on hand May 15, 1883, to be $1732, and the expenditures $591; balance in treasury, $1141.

The following voluntary papers were then presented:

Near-sightedness Developed during School-life, by F. C. Holz, Chicago. This paper was a repetition of the investigations of Javal.

Sudden Suppression of Catamenia, by Dr. Whitmeyer, of Metamora.

General Principles of Treatment of Pott's Disease, by J. C. Webster, M.D., of Chicago.

Pancreatic Anæmia, by C. W. Earle, M.D., of Chicago. An excellent paper, based on four cases of cirrhosis of the pancreas, with symptoms of pernicious anæmia, accompanied by reports of autopsies of all the cases.

Mastoid Abscess, by E. L. Holmes, M.D., of Chicago.

Purulent Inflammation of the Middle Ear, by Dr. H. Gradle.

PRIZES.

DR. WALTER HAY offered a resolution, which was adopted, offering a prize of one hundred dollars for the best paper on "Diphtheria;" and one hundred dollars for the best paper on ten cases of any disease, in tabulated form, occurring in the practice of the writer, to be read at the next meeting of the Society. The prizes are to be awarded by a committee of three, to be appointed by the President.

THE PRACTICE OF MEDICINE IN ILLINOIS.

DR. E. INGALS offered a resolution, which was adopted, requesting the passage of a law to prevent anyone from practising medicine in Illinois unless a graduate of a respectable medical college.

Adjourned.

A BANQUET

at the Grand Pacific Hotel, tendered the delegates by the medical profession of Chicago, took place on Wed-

nesday evening, May 21st. CHARLES GILMAN SMITH, M.D. (University of Pennsylvania), presided as toastmaster in the happiest manner. Owing to the wise selection of toasts and speakers, the banquet proved a brilliant success.

THE LOUISIANA STATE MEDICAL SOCIETY.

Stated Annual Meeting, held at Baton Rouge, May 21, 22, and 23, 1884.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, MAY 21ST—FIRST DAY.

THE Society was called to order at 11.55 A.M., by THE PRESIDENT, DR. J. P. DAVIDSON, of New Orleans.

DR. J. W. DUPREE, of Baton Rouge, Chairman of the Committee of Arrangements, then introduced Hon. G. L. Day, Mayor of the City of Baton Rouge, who welcomed the Society to this city.

DR. R. H. DAY, in behalf of the Baton Rouge Medical Association, extended a cordial and paternal greeting to the Society. He took occasion, in the course of his remarks, to call attention to the ignorance of the people of, and their indifference to, matters of sanitation. He urged upon the members of the Society the paramount duty of instructing the people in the fundamental principles of sanitary science, and of appealing to the General Assembly for appropriate legislation on this subject.

DR. E. M. HOOPER, of East Feliciana, moved that a Committee on Credentials, consisting of five members, be appointed. Carried.

Pending the appointment of the committee, on motion of DR. BICKMAN, the rules were suspended and the following physicians were proposed, and by acclamation

ELECTED MEMBERS OF THE SOCIETY:

Dr. Samuel F. Mecker, of Rapides; Dr. T. P. Vaughn, of West Baton Rouge; Dr. King Holt, of Iberville; Dr. H. D. Bruns, of New Orleans; Dr. Stanhope Jones, of New Orleans; Dr. D. C. Tebault, of New Orleans; Dr. G. B. Lawrason, of New Orleans; Dr. J. H. Bemiss, of New Orleans; Dr. T. Hebert, of Iberia; Dr. Bernard, of East Carroll; Dr. T. J. Buffington, of East Baton Rouge; Dr. W. O. White, of Vermillion; Dr. W. B. Meng, of Concordia; Dr. L. F. Reynaud, of Baton Rouge; Dr. J. B. Duchin, of East Baton Rouge.

THE PRESIDENT then announced the following

COMMITTEE ON CREDENTIALS:

Dr. Hooper, of East Feliciana; Dr. Bickham, of New Orleans; Dr. Fish, of Rapides; Dr. Tebault, of New Orleans; Dr. Henry, of New Orleans.

The Committee after a short recess reported the credentials of all delegates in correct form.

REPORTS OF OFFICERS.

The report of the Corresponding Secretary, in his absence, was read by Dr. J. H. Bemiss, of New Orleans.

The report of the Treasurer showed that eighty members were in arrears as to annual dues. Of a number obligating themselves at the last annual meeting to pay an additional five dollars towards the maintenance of the Society, ten were in arrears. Estimating these sums as collectable, and adding the amounts now in the Treasurer's hands, the assets of the Society were shown to be $646.

DR. DAVIDSON, Chairman of the Committee on Organization, to which had been referred the

EXPEDIENCY OF FORMING A TRI-STATE MEDICAL SOCIETY,

of the States of Texas, Arkansas, and Louisiana, reported adversely on the same. Also adversely on the granting of certain privileges to those members subscribing an additional five dollars. The adoption of the report was made a special order for to-morrow's session.

EVENING SESSION.

DR. DAVIDSON delivered the

ANNUAL ADDRESS,

the tenor of which was a more complete organization of the Society, as a necessity for the well-being both of the profession and the public in general. To this end, he urged the formation of affiliating parish societies. By better organization and more numerous delegates, we could hope to spread among the people a better knowledge of sanitation and hygiene, and could also hope to obtain more efficient legislation. Moreover, with parish affiliating societies, vital statistics—so important to the advancement of our knowledge, both general and practical—could be collected and analyzed. He then touched upon the formation of a State Board of Health, and ended by stating in detail a plan by which vital statistics and mortuary reports could be collected, and, through the State Board, be classified, tabulated, and studied.

COL. K. A. CROSS then delivered an address on *The Principles Controlling the Mind and Directing the Tendencies of the Age.*

The paper was listened to with much interest, and at its conclusion was referred, with a vote of thanks, to the Publication Committee.

THURSDAY, MAY 22D—SECOND DAY.

MORNING SESSION.

A letter from Dr. Hardie was read, stating that he was compelled to go home, and calling the attention of the Society to the following points:

a. The clause in the Constitution of the State whereby any debt save that to a physician could be satisfied by a lien on property. It should be extended so as to include debts to physicians.

b. While tools of an artisan were free from seizure by the Constitution, a physician's books and instruments owned no such immunity.

c. That the law with reference to the registration of physicians be amended so as to be more efficient.

d. The extra fees paid by certain members be considered as fees for the ensuing year.

e. That his essay on *Germs and Contagion*, if found worthy, be read and referred to the Publication Committee; if not, that it be returned into his hands.

DR. HOOPER moved that suggestions *a* to *d*, inclusive, be referred to the Committee on State Medicine, and suggestion *e* to the Publication Committee. Carried.

DR. LOVE recommended Dr. W. A. Burris, of Ascension, for membership; Dr. Guilbeau, Dr. Leslie.

DR. CHAILLÉ, of New Orleans, moved that the rules

be suspended, and that the gentlemen be elected by acclamation, which was done.

THE COMMITTEE ON STATE MEDICINE

reported through its Chairman, DR. S. E. CHAILLÉ, of New Orleans, that it had placed in the hands of Judge Sevy the following subjects, to be elaborated into bill form, and presented to the General Assembly:

1. Law for the creation of a State Board of Health, whose members shall be selected from the various districts of the State.

2. Law to protect confidential communications to physicians of a professional character.

3. Law requiring the teaching of hygiene and elementary physiology in the public schools.

The Committee also reported that, deeming it very desirable to prevent the practice of obstetrics throughout the State by ignorant midwives, they nevertheless deemed it inexpedient to press for legislation on the subject at this time.

DR. CHAILLÉ then read the printed petition of the Auxiliary Sanitary Association and other scientific bodies, praying the General Assembly to pass a law making instruction in the elements of hygiene and physiology compulsory in the public schools. Dr. Chaillé then moved that the Society endorse this petition. Carried.

THE PRESIDENT announced the appointment of a

NOMINATING COMMITTEE

in order, and stated that at the last meeting this Committee had been formed by the members from each parish selecting one of their number to represent them in the Committee. He urged that the same method be pursued, and declared a recess of ten minutes for the choice of the Committee.

The Committee subsequently reported, through its Chairman, the following nominations for

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. R. H. Day, of East Baton Rouge.

Vice-Presidents.—Drs. C. J. Bickham, of New Orleans; E. S. Lewis, of New Orleans; T. J. Buffington, of East Baton Rouge; C. M. Smith, of Franklin; I. J. Newton, of Bastrop; T. J. Allen, of Shreveport.

DR. DAY moved that the rules be suspended, and that Drs. I. A. Williams and Kauffman be elected members of the Society. Carried.

DR. BRUNS, of New Orleans, read a paper on

ACUTE PLASTIC IRITIS,

which was based upon an analysis of fifty-five cases treated in the Charity Hospital during the past sixteen months. He stated that a knowledge of the disease by the general practitioner was desirable, because of its frequency, five per cent. of all eye cases treated in the Hospital being of this nature. He said that out of the fifty-five cases, thirty-three were undoubtedly due to syphilis. He pointed out that the disease could be recognized by the peculiar redness, the character of the pain, and the functional impairment of the pupil, and urged prompt and vigorous treatment with strong solution of atropia sulphate, mercury, and hot-water fomentation; and called attention to the fact that in no case had the patient applied for treatment at an earlier date than the seventh day, and his tables showed that this date having been passed, no influence upon the results seemed to have been exerted by any delay in the institution of treatment, even up to the thirty-fifth day. The main feature of the paper was its clearness and simplicity.

DR. G. B. UNDERHILL, of New Orleans, read a paper on

THE SPLEEN; ITS ANATOMY, PATHOLOGY, AND SOME OF ITS LESIONS,

which dwelt especially upon the *rôle* played by the unstriped muscular fibres in this viscus; upon the action of the organ as a reservoir for superfluous blood of the circulation; and upon the influence of the chronically enlarged spleen upon the healing of wounds near the rectum. He also dwelt at length upon the pathogeny of chronic splenitis with enlargement in malarial fever.

The Secretary read a paper by DR. M. SCHUPPERT, who was absent, on

TETANUS AND TETANY.

He took the ground that tetanus, which is invariably preceded by a wound, is the result of blood-poisoning due to some microörganism. This point was supported by strong analogical reasoning. On the other hand, the author maintained that tetany, which may be readily differentiated from tetanus by a number of well-marked symptoms enumerated by the author, is a disease of the central nervous system, and not fatal in its nature. This highly interesting paper was of such a nature as not to admit of a fair synopsis, and will be published in the *Transactions* for 1884.

Dr. Hardie's paper on *Contagion and Germs* was read by the Secretary.

ANÆSTHETICS.

DR. UNDERHILL moved that a committee of three be appointed to obtain from all reliable sources data with reference to sulphuric ether, chloroform, and a mixture of ether, chloroform, and alcohol.

DR. DAY said that the manner of administration is probably the most important factor in the production of unfortunate results, and statistics should be compiled with especial reference to this point.

DR. E. S. LEWIS did not consider it a matter for investigation by the Society, but thought that Dr. Underhill should rather make it a subject of personal investigation to be reported upon by him at the next annual meeting.

DR. CHAILLÉ thought that the Society might do a useful work by lending its influence to the investigation, and added that the Society should make it a point always to assist the younger members in their work. Motion unanimously carried.

DR. DAY moved a vote of thanks to the readers and writers of the papers which had been read. Carried.

EVENING SESSION.

THE PRESIDENT announced the following Committee on Chloroform, as contemplated by the resolution introduced in the morning: Dr. G. B. Underhill, Dr. H. D. Bruns, Dr. G. B. Lawrason.

MEDICAL LEGISLATION.

JUDGE SEVY being introduced, stated that he had come before the Society by request, to offer some state-

ments with reference to points for legislation, which had been introduced by this and other cognate bodies. The first point for legislation was the establishment of a State Board of Health. Though it was neither desired nor intended that any reflections be cast upon the present or preceding Boards of Health, still it was universally acknowledged that the Board, as now constituted, is only a local Board, and withal patched and repatched by law upon law, until its usefulness was dangerously curtailed. The proposed law contemplated a veritable State Board composed of representative physicians and others from all parts of the State, with the Secretary a physician and with powers both corporate and politic. The second recommendation for legislation was the protection of confidential communications to physicians by patients. He could see no difficulty in the way of the passage of this bill. The next was sanitary instruction. This is formulated in the memorial of the physicians in this way: that public schools throughout the State should teach physiology and hygiene. He would suggest that the request of the Women's Christian Temperance Union be acceded to, and the addition made "with special reference to the affects of the abuse of alcohol, narcotics, and anæsthetics." Compensation for expert testimony. He was in favor of such an Act, and hoped for its success. Insane criminals. This proposed law looked partly to the checking of the too frequent pleading of insanity for crime, and the prevention from punishment, and the taking care of the actually insane. It was a good move. The Coroner, his selection and duties. Public institutions, the giving of control of, to the State Board of Health. The practice of pharmacy, a law designed to prevent the selling of poisons and adulterations, and the prescribing by druggists. All of these were good, and he hoped they would pass.

DR. F. FORMENTO, of New Orleans, read a paper on

CREMATION.

He spoke of the prejudice existing against this practice, and contended that it did not conflict with any religion. He cited many instances to show its great antiquity and its present revival. He discussed the effects of inhumation upon the living, and concluded by describing the *modus operandi* of cremation and the absence of anything whatsoever, save prejudice, calculated to shock the most sensitive or the most bigoted.

FRIDAY, MAY 23D—THIRD DAY.

MORNING SESSION.

DR. J. H. BEMISS offered a resolution to the effect that the Society express its interest in the success of the Exposition, and that it urge upon its members individually, and upon affiliating and other medical societies throughout the State, that they exert themselves to forward in any manner in their power, any plans or specimens by which the Managers of the Exposition may propose to illustrate the natural history and resources of the State.

QUARANTINE.

DR. CHAILLÉ said that Col. Zacharie, the Attorney of the Board of Health, was present, and would be pleased to state in a few words the projected action of the Board. The first was a proposition to invite, in the month of June, a conference of health authorities of the neighboring States, the object being to come to an understanding as to the duties and responsibilities of each in matters of health, and especially quarantine.

The next proposition was the establishment of a lower quarantine station. He spoke of the history of quarantine in the State, tracing the gradual removal, from year to year, of the station, until at present it was forty miles below the city. It was now proposed to have two stations, one near the mouth of the river, but in one of the unused passes, where vessels actually infected could be detained and attended; and the other at the present point, where only those vessels would be allowed to anchor which had hailed from an infected port, or one proclaimed as infected, but were themselves healthy. The objection to sending ships to Ship Island was twofold. The State has no control over ships out of the waters of Louisiana, and captains ran the risk of forfeiting their insurance if they deviated from the course laid down in their papers.

COL. ZACHARIE spoke of the arrangments which had been perfected to carry out their plans just so soon as the Legislature authorized them to do so. He spoke of the Declaration of the International Quarantine Assembly of Europe, promulgated years ago. By this declaration infected vessels could always be sent to lazarettos, which were convenient and numerous, but never until aid of needed kind was furnished. He went on to speak of the non-intercourse policy of Louisiana, and how all the world disapproved of it; among others he would cite especially the ex-President of the Board of Health, Dr. Joseph Jones. He pictured the spectacle of an infected ship in a time when every seaport had declared a policy of absolute non-intercourse. Refused admission at every port, unaided by food or medicine, drifting helpless upon the waters, it would stand as an awful commentary upon an age which allowed such inhumanity and barbarism.

DR. CHAILLÉ thought such occurrences entirely unnecessary, and easily avoided if, when a State decides to adopt a non-intercourse policy, it so declare its intention not *ten* days before, but months—three to six months—before the proclamation goes into effect. He believed that the moiety of trade with the proclaimed port was nothing to the vast stream of commerce which flowed to us from the West, and that one yellow fever epidemic in twenty years did New Orleans and Louisiana more damage than non-intercourse for forty years. He added that, even with the facilities now existing at the Quarantine Station, ships were detained. Unloading and disinfection of vessels should be done with dispatch.

COL. ZACHARIE reviewed the means by which disinfection was practised, and stated that arrangements for laborers and warehouses were complete.

DR. S. JONES stated that this non-intercourse policy had been adopted and recommended, not by his father, Dr. Joseph Jones, but by a special meeting, called for the purpose, in conjunction with a conference committee.

DR. CHAILLÉ, though thinking as he had before indicated, moved that the Society heartily approve any measures adopted by the Board designed to separate infected and non-infected vessels. Resolution adopted.

DR. LOWE remarked that, at the last meeting, the Society had endorsed

VACCINATION AND REVACCINATION.

He was sorry to say that his experience had been such as to compel him to ask the Society to again so express itself. He, therefore, offered a resolution endorsing vaccination and revaccination, and urging the police juries of the parishes to give the matter their earnest attention.

After some discussion of the powers of police juries in the matter, the resolution was carried.

The PRESIDENT-ELECT, DR. R. H. DAY, announced the usual committees, and then, on motion, the Society adjourned, to meet in New Orleans, on Wednesday, January 14, 1885.

THE MEDICAL ASSOCIATION OF THE STATE OF MISSOURI.

Twenty-seventh Annual Session, held at Sedalia, May 20, 21, and 22, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, MAY 20TH—FIRST DAY.

THE ASSOCIATION was called to order by THE PRESIDENT, DR. E. H. GREGORY, of St. Louis.

DR. OHMANN-DUMESNIL, of St. Louis, presented a paper on

ECZEMA,

written, he said, for the purpose of calling out suggestions in the treatment of that very troublesome affection, but no one seemed to have discovered anything new on the subject.

DR. GREGORY, of St. Louis, spoke of a case of local eczema confined to the lower extremities which he had treated by confining the patient to his bed and elevating his feet.

DR. G. M. DEWY, of Keytesville, then presented a paper on *The Cause and Cure of Quacks and Quackery.*

AFTERNOON SESSION.

Prominent among the papers read during the afternoon session was one by DR. GLASGOW, of St. Louis, in which he reported a

CASE OF SLOW PULSE,

ranging from thirty-eight to forty-five per minute. The patient suffered from general nervous excitement, and he thought that the slow pulse came from over-stimulation of the pneumogastric nerve. The heart acted as if its inhibitory nerve was being galvanized, The pulse became normal when the general nervous symptoms were relieved.

DR. TEHOLSKY, of St. Louis, spoke of several cases in his practice of very slow pulse, in two or three of which there had been autopsies, and in each the coronary arteries were found occluded. He thinks that a majority of such cases are caused by disease of those vessels and malnutrition of the heart.

DR. LESTER, of Kansas City, spoke of an apparently healthy soldier who had been looked upon as a curiosity by his comrades, on account of his slow pulse, which ranged from 35 to 45 at the wrist, and was not very strong. When the ear was placed over the heart, to each radial pulsation there could be distinguished two distinct "thrub-dubs," showing that his heart did beat as often as those of other men. But as every alternate contraction seemed to give a light sound, he thought that these impulses failed to reach the radial artery.

EVENING SESSION.

This session was principally occupied in reading the reports of the Committee on The Relation of Spirit-drinking, Insanity, and Crime, which showed a vast amount of assiduity in searching to secure facts. The committee had communicated with almost every asylum and penitentiary within the United States, and had secured not a little valuable information from foreign countries.

DR. POTTER, of Cameron, Chairman of the Committee, estimated that sixty-five per cent. of all crimes committed in this country were directly or indirectly caused by the drinking of alcoholic liquors; and that seventy-five per cent. of all the inmates of insane asylums were there as a result of the use of the same intoxicants, either by the subjects themselves or some one or more of their ancestors in the first or second generation back.

DR. HART, of Brownsville, brought in a minority report, which was in substance the same as Dr. Potter's paper. He estimated the per cent. of crime caused by liquor at seventy-five, and the insanity at eighty.

WEDNESDAY, MAY 22D—SECOND DAY.

DR. E. H. GREGORY, of St. Louis, delivered

THE PRESIDENT'S ADDRESS,

choosing for his subject, *Neoplasms from a Practical Standpoint.*

After stating that some authors claim that all neoplasms are inflammatory, he asserted that they are not so, since inflammation is a constructive process and always comes to the aid of nature when any part is to be protected or repaired, while the formation of "tumor neoplasm" is essentially a destructive process.

The point of practical interest to the surgeon is in diagnosticating between inflammatory and non-inflammatory neoplasms. If they are inflammatory, they tend to cure themselves; if non-inflammatory, unless there is some special reason, they are malignant or benign. If the neoplasm is of the tumor variety, to distinguish whether it is malignant or benign is a secondary consideration, for in either case the watchword is to operate early.

AFTERNOON SESSION.

DR. HARDAWAY, of St. Louis, read a paper on *Idiopathic Sarcoma of the Skin.*

DR. P. V. SCHENCK, of St. Louis, then read a paper entitled *Periodic Pains Caused by Diseases of the Womb and its Appendages, not Relieved by Antiperiodics.* He reported a number of cases in which the patients had suffered by periodical pains, and in which quinine even in large doses was used without affording relief. He found in all of these cases an unhealthy condition of the womb or its appendages, and he relieved the pain by local treatment.

DR. ENGELMANN, of St. Louis, agreed with Dr. Schenck as to the non-malarial origin of some of the

periodic pains which women suffer, but thought it safe to give quinine.

DR. FITZGERALD, of Lathrop, suggested sulphate of nickel as a remedy for the relief of non-malarial periodic pains.

THURSDAY, MAY 22D—THIRD DAY.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. H. H. Middlekamp, of Warrenton.

Vice-Presidents.—Drs. T. F. Prewitt, of St. Louis; W. E. Evans, of Boonville; B. G. Dysart, of Paris; H. W. Lane, of Jasper; S. G. Griswold, of New Haven.

Recording Secretaries.—Drs. J. H. Thompson, of Kansas City; N. M. Baskett, of Moberly.

Corresponding Secretary.—Dr. F. J. Lutz, of St. Louis.

Treasurer.—Dr. C. A. Thompson, of Jefferson City.

After reading several papers by title, and referring them to the Committee on Publication, the Association adjourned to meet in St. Joseph, on the second Tuesday in May, 1885.

THE NEBRASKA STATE MEDICAL SOCIETY.

Sixteenth Annual Meeting, held in Omaha, May 13 and 14, 1884.

(Specially reported for THE MEDICAL NEWS.)

THE sixteenth annual meeting of the Nebraska State Medical Society was called to order in Falconer's Hall, Omaha, May 13, 1884, at 10 A.M., by the Secretary, Dr. A. S. Mansfelde, as neither the President nor either of the Vice-Presidents was present. On motion, Dr. Shipman, of Sterling, was elected Chairman. The Society at its last meeting consisted of one hundred and thirty members; this number has been increased by the election of forty-five applicants.

THE REPORT OF THE SECRETARY

was then read. In it he suggested the advisability of his being authorized to collect, by means of suitable blanks distributed to the members, statistics of births, deaths, prevailing diseases, etc. This suggestion was subsequently embodied in a resolution and adopted.

THE COMMITTEE ON FOREIGN CORRESPONDENCE

suggested a plan, similar to the governmental consular system, for the appointment of members of foreign societies as representatives of this Society, and inviting the foreign societies to delegate members of this Society to represent them in its proceedings, to the end that knowledge of the advances in medical science be the more readily and thoroughly disseminated.

THE REPORT OF THE CORRESPONDING SECRETARY

recited a list of the reports received from other State Societies, and recommended the reprinting of the first ten years' *Proceedings* of this Society, the editions of which are exhausted.

THE REPORT OF THE TREASURER

showed a balance in the treasury amounting to $364.20.

At 2 P.M. the Society met in Scientific Session. The first paper read was that of DR. MERRIAM on

RECENT PROGRESS IN THE TREATMENT OF DIPHTHERIA,

in which he took the ground that the greatest progress made had been in the growing disposition to use small doses, frequently repeated, of the tonic and stimulant medicines usually given.

This paper excited much discussion, participated in by many of various views, though most agreed in the number and quantity of remedies used.

DR. BAUER, of St. Louis, Mo., lauded the use of eucalyptol locally.

DR. CARTER presented the report of the Section on

PRACTICAL MEDICINE, PATHOLOGY, AND SPECIAL THERAPEUTICS,

and, in alluding to ethics, said that "while they are outwardly strict adherents to the Old Code, the physicians of Omaha really go beyond the New Code, practising on the principle 'every man for himself.'" This remark called forth indignant denial, and, on motion, was stricken out.

AMENDMENTS TO THE CONSTITUTION

were adopted, as follows:

The deliberations of this Society shall be according to Roberts's Rules of Order.

All officers shall be elected for one year, except the Secretary, whose term of office shall continue until he resigns or is removed.

The chairmen of sections shall be selected by a committee of three, appointed by the President at the beginning of each annual meeting; and each chairman shall, before appointment, promise to report an epitome of the progress made in the preceding year in his section.

QUALIFICATIONS FOR MEMBERSHIP.

DR. W. M. STONE moved that there be required from candidates for membership of this Society the same qualifications as are demanded by the Illinois State Board of Health. Adopted.

Reports from the various standing committees were read and accepted.

THE ELECTION OF OFFICERS

for the ensuing year resulted as follows:

President.—Dr. F. G. Fuller, of Lincoln.

Vice-Presidents.—Drs. G. N. Peebles, of David City, and M. J. Gahan, of Grand Island.

Permanent Secretary.—Dr. A. S. Mansfelde, of Ashland.

Corresponding Secretary.—Dr. R. R. Livingston, of Plattsmouth.

Treasurer.—Dr. R. C. Moore, of Omaha.

Grand Island was selected as the place for holding the *next annual meeting.*

MAY 14TH—SECOND DAY.

THE REPORT OF THE SECTION ON SURGERY

was presented by DR. LIVINGSTON, CHAIRMAN, and contained papers by several members on various topics and a *résumé* of the advances in the surgery of organs formerly sacred from invasion by the surgeon's knife; the surgery of the heart, lungs, œsophagus, stomach, pylorus, kidneys, spleen, liver, and intestines. It also referred to the administration of anæsthetics *per rectum.*

In the discussion that followed, DR. MERCER related four cases of *Stricture of the Œsophagus,* and expressed his preference for dilatation over operative procedures.

THE REPORT OF THE SECTION ON OBSTETRICS,

by DR. ROBBINS, CHAIRMAN, was an account of the discoveries and inventions in that department.

DR. LEISENRING read a paper on *Puerperal Fever*, which was followed by a discussion between those who hold that it is a specific disease developed from a specific poison, and those who believe it may originate from the absorption of any septic matter.

DR. MANSFELDE reported four cases of

OVARIOTOMY,

in which the most elaborate antiseptic measures were employed. Three of the cases were successful. The other one, an unpromising case, died on the second day after the operation.

DR. CHAPIN read a paper on *Medical Education*, in which he assailed vigorously the allo-homœo-eclectic department of the State University.

Other reports, for lack of time, were read by title and referred to the Committee on Publication.

In the early evening a session was held for the inauguration of the newly elected officers and the customary speech-making. After a resolution of thanks to the outgoing officers, the Society adjourned *sine die*.

At the Millard Hotel, at 10 P.M.,

A RECEPTION AND BANQUET

was tendered the members of the State Society by the Omaha Medical Society.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 15, 1884.

THE VICE-PRESIDENT, HORACE T. HANKS, M.D., IN THE CHAIR.

DR. D. BRYSON DELAVAN read a paper on

PRACTICAL SUGGESTIONS UPON THE ALIMENTATION OF PATIENTS SUFFERING FROM DYSPHAGIA.

(See page 663.)

DR. JOHN C. PETERS said that in regard to the admirable method of artificial alimentation described by Dr. Delavan there could be very little to add, as he had set the whole matter so clearly before the Academy. He thought it would be a mistake to resort to it, however, in many cases of the acute affections referred to in the paper. He had found in some cases of diphtheria and other diseases especially implicating the throat (and he had to confess that it had been somewhat a matter of surprise to him) that food and stimulus were not so essential to a favorable issue as was generally supposed. He found sometimes, therefore, that at the present day the profession had gone too far to the opposite extreme of the practice observed in former times, when, as was now commonly said, the patients were "starved to death." He felt convinced that medical men now resorted to over-feeding and over-stimulation; and he said that in many cases of disease he did not think the treatment as judicious as that of forty years ago.

DR. E. C. HARWOOD thought that the paper was one of great interest and practical value, and that the method described in it was a very simple and efficient one. In some of the kinds of cases referred to by Dr. Delavan, he had himself at times employed the Davidson syringe with a small tube, and found that it had answered a good purpose. In some of the cases of acute disease, however, he thought the difficulty of swallowing could sometimes be relieved without having to resort to the use of the œsophageal tube. He then mentioned a very bad case of tonsillitis, with marked dysphagia, occurring in the practice of another Fellow of the Academy, which he was hastily summoned to see in consultation late one night. Not knowing the nature of the case, but learning that it was prominently characterized by throat obstruction, he went prepared to perform tracheotomy. On reaching the patient's bedside, he found the case of the character mentioned, and as the other physician had not yet arrived, he concluded to try the effect of thoroughly cleansing out the pharynx and nasal passages with warm water and salt. This he accomplished by means of a post-nasal syringe of his own device, and the patient, having got rid of a large accumulation of ropy mucus, was so much relieved that he was at once able to swallow with avidity a bowl of beef-tea. The effect of this was very invigorating, and the urgency of the symptoms was now so far mitigated that it was unnecessary to resort to tracheotomy or other severe measure.

DR. BRANDEIS, while agreeing in the main with the views of the author, said that he knew of but few patients to whom he would feel willing to trust the use of the apparatus in their own hands, feeling afraid that the mucous membrane might be lacerated, or the diseased parts seriously injured in the endeavor to pass the tube. But, granting that it could be trusted to some adult patients, it certainly could not to children, and it seemed to him an objection to the method that it would require such constant attendance on the part of the physician, since the feeding would have to be repeated at comparatively frequent intervals.

Dr. Krishaber, of Paris, had proposed, in the case of permanent stricture of the œsophagus, to introduce a tube through the nose and pharynx into the œsophagus, past the point of stricture, and leave it there indefinitely, and one case had been reported in which the tube remained in position for one hundred and fifteen consecutive days. This plan, he thought, could be adopted with advantage in many of the cases to which Dr. Delavan had referred. There was, at present, under his own care a case of undoubted stricture of the œsophagus in a man forty-five years of age, which was associated with cretaceous degeneration of the thyroid and accompanied by difficulty of deglutition; and a catheter had now been *in situ* for the greater part of four weeks. Every two or three days the patient would come to his office, when he would withdraw the tube, and, after allowing the parts to rest for an hour or two, introduce a new one. He employed an ordinary black rubber tube about eight or nine millimetres in diameter. In acute affections, such as quinsy sore throat, he had not met with much difficulty in getting patients to take soft and bland food, and under the circumstances there was, perhaps, nothing so good as a raw egg. This he directed the patient to place in a wine-glass with a little sherry, or whatever else was preferred to flavor it with, and drink it down at one gulp. The whole cavity of the pharynx was thus bathed with a bland substance, which itself was of service in allaying pain and irritation. In acute tonsillitis, if there was no apparent danger from diph-

theria or other septic influence, he was also in the habit of making simple scarifications over the organs, which relieved the dysphagia in a very prompt manner.

DR. GEORGE L. PEABODY said that it had occurred to him to suggest the use of one other device in this connection, and that was an ordinary condom with the end cut off. A portion of this the patient could swallow himself after it had been moistened, and we would then at once have a tube in position for the introduction of as much food into the stomach as was deemed necessary. He had not as yet had an opportunity of carrying this suggestion into practical effect.

DR. W. C. JARVIS said that the method set forth by Dr. Delavan seemed to him to fulfil every indication in which it was possible to use this form of apparatus; but there were certain conditions which we were liable to meet with in which the epiglottis was the special seat of ulceration (as was sometimes the case in syphilis and laryngeal phthisis), and in which it was altogether out of the question to use any kind of œsophageal tube, on account of the extreme pain which it would occasion. In this class of cases he had been of late using, with very successful results, the soft capsules prepared by druggists for the administration of castor oil and other disagreeable medicines, which could be swallowed without difficulty even by such patients. The capsules were filled with the desired fluid food, or stimulus, by means of a hypodermatic needle attached to a tube, and the small orifice was then sealed up. He could speak of this method with confidence, because he had already given it quite an extensive trial. In regard to cases of tonsillitis, such as the one referred to by Dr. Harwood, in which death was threatened from suffocation, he would like to remark that when he met with them he did not hesitate for an instant to excise the tonsil, which could always be done without difficulty, and which usually obviated the necessity of tracheotomy.

DR. DELAVAN, in closing the discussion, said, with reference to the criticism of Dr. Brandeis, that patients ought not to be trusted with the apparatus themselves, that he would not think of doing this in any case in which the patient was not a person of intelligence and judgment; but it required only a little skill and practice to introduce successfully the tube, and he thought that patients, as a rule, when they were once accustomed to it, preferred to pass it for themselves rather than have it done by the physician. When the patient was not capable of doing this, or preferred not to pass it himself, he could not see why a trained nurse could not be employed, who, with a little special instruction and practice, could probably do it as well as the physician himself. But, if in any case the physician felt that it would be unsafe to entrust the procedure to other hands, or if no efficient person could be procured, it was plainly his duty to go and feed the patient as often as was necessary, just as in another case it might be his duty to give a hypodermatic injection of morphia, for instance, two or three times a day. As to Krishaber's method, it was especially adapted for stenosis of the œsophagus, and he did not think its employment would be satisfactory in the class of cases referred to in the paper. In tonsillitis there was often a very marked degree of dysphagia; and here the tube could be used with little difficulty and with very satisfactory results. Dr. Jarvis's suggestion in regard to the use of soft capsules, he thought a capital one; and he was extremely glad to have heard it, because it just met the difficulty in the class of cases referred to, in which there was special sensitiveness in the vicinity of the epiglottis, and therefore admirably supplemented the use of the apparatus to which he had called attention this evening, in the alimentation of patients suffering from dysphagia.

DR. ROBERT W. TAYLOR then read a paper on

CHANCRE OF THE TONSIL.

Having explained that the lesion of the tonsil of which he wished to speak was true chancre alone (to the exclusion of chancroid), he stated that it was not so rare as had hitherto been supposed. As to its origin, chancre of the tonsil might be due to kissing, the contact of pencils, glasses, bottles, and perhaps, cigars, with the mucous membrane of the mouth, and also to depraved and unnatural sexual contact, which, he regretted to say, had become alarmingly frequent in the community. In November, 1882, he was asked by Dr. Charles McBurney, to come to Bellevue Hospital, to see a boy nine years of age, in his wards, who was suffering from a fracture of the tibia, and who, since he had been under treatment at the hospital, had developed a well-marked attack of acute secondary syphilis, with undeniable chancre of the tonsil. Dr. Taylor then read the full history of the case as detailed by the House-surgeon at Bellevue; from which it appeared that the syphilide (roseola), the true nature of which was not immediately recognized, was first noticed on the boy's chest on the 12th of November. On the 15th, the chancre was discovered on the left tonsil, and anti-syphilitic treatment was commenced. The tonsil was swollen and covered with a white membrane, and the cervical glands in the vicinity were much enlarged. The boy confessed that a short time previously a strange man had placed his penis in his mouth in a water-closet.

In June, 1882, a young woman of promiscuous habits, who was under his care at the time for other troubles, complained to Dr. Taylor that she had a slight sore-throat. On making an examination, he found that the left tonsil (both tonsils were chronically enlarged) was somewhat red, though it was not hard, and the ganglia were not perceptibly enlarged. Under the circumstances, he ordered a simple gargle, and awaited events. The patient then went out of town for nearly a fortnight, and when she returned, he found the left tonsil was much swollen and indurated, while the ganglia were enlarged and matted together. Three weeks later, the inguinal glands became implicated, and a roseolous syphilide appeared. The chancre on the tonsil was found to have originated from unnatural practices.

Dr. Taylor next referred to four other cases which he had either seen himself or which had come within his immediate knowledge. The first he had had an opportunity of seeing through the courtesy of Dr. George H. Fox, and it was in a man who exhibited the most disgusting depravity in speaking of the practices to which he was addicted, and through which he became infected with chancre of the tonsil. The second was that of a young man who had a chancre of the left tonsil, and at the time was suffering from a tubercular syphilide. The third case was one of great interest, for the history of which he was indebted to Dr. Edward Wigglesworth, of Boston. It occurred in a medical

student who contracted chancre of the right tonsil while placing his mouth in contact with that of an asphyxiated newly born infant, whom he was endeavoring to resuscitate, which was followed by well-marked constitutional syphilis. The fourth and last case, originating from indulgence in beastly practices, was related to Dr. Taylor with great minuteness by the late Dr. F. J. Bumstead, so that he could thus present six well-authenticated cases of chancre of the tonsils, all of which were followed by constitutional syphilis, and from all of which all other sources of infection were eliminated. The other cases that had thus far been reported were two by a Russian writer, one by Spillman, and four occurring under the observation of Fournier.

Dr. Taylor then spoke of the clinical history of chancre of the tonsil. The first appearances were redness and swelling, without perceptible adenitis. The severity of the symptoms then increased, and induration and ulceration were noticed, while a grayish-white coating might be irregularly spread over the ulceration. The differential diagnosis had to be made between chancre on the one hand, and mucous patches, syphilitic sclerosis, or epithelial cancer on the other. In the syphilitic lesions referred to, the trouble would not be so completely confined to one side, and there would be by no means such marked adenopathy, while the history would, as a rule, throw light on the matter.

In conclusion, Dr. Taylor said that the following points would render the diagnosis of chancre of the tonsil practically certain. First, the details of infection, whether from kissing, from contact of such articles as had been referred to, or from indulgence in bestial practices. Second, the slow, insidious development of the lesion, which runs a subacute course. Third, its unilateral position. Fourth, difficulty of deglutition, and even pain, referred to one side. Fifth, the special implication of the preauricular gland. Sixth, much less induration of the glands in general—particularly those at a distance from the throat—than is usually met with in connection with ordinary chancre.

DR. F. N. OTIS said that he had never himself observed a case of chancre of the tonsil, but that he saw no reason why the lesion should not occur in this position as well as elsewhere. All that was required for the development of a chancre was, first, a *contagium*, and, second, an open surface on the part of the patient affected. He believed, however, that there was a very great variety in the initial lesions of syphilis, the appearances and developments often differing very widely in different instances. All the diagnostic points referred to by the author of the paper might not be present in certain instances, and, therefore, if we were to wait for them to make their appearance, we might lose the opportunity of locating the initial lesion. The latter was not necessarily associated with any destruction of tissue whatever. In some cases he had observed simply a little hard nodule on the genitals; but from this followed glandular enlargement, with the dissemination of the syphilitic virus throughout the system. Such nodules might be absorbed without undergoing any ulcerative process whatever, but, none the less on this account, they are just as much the true initial lesions of syphilis as typical Hunterian chancres. Dr. Otis then related a case which had been referred to him, and which previously had been under the care of two distinguished oculists, in which there was at first merely a little red point on the conjunctiva. From this there was a gradual extrusion of conjunctivitis; but after the patient had been under treatment for several months for the condition of the eye, it was noticed that there had occurred a considerable enlargement of the parotid gland, the lymphatics above it, and the post-cervical glands. During the fourth month after the trouble in the eye commenced, a roseolous eruption appeared, and the case was referred to Dr. Otis, who found it an unmistakable one of constitutional syphilis. The interest of the case centred in the fact that the starting-point of the whole trouble was the little red spot on the conjunctiva, as a careful investigation of the history established the fact that this was undoubtedly the initial lesion of syphilis. It showed, therefore, that we could not always depend on the presence of the usual diagnostic signs in the initial lesions. The cases which Dr. Taylor had reported were worthy of note from a moral and social point of view, but otherwise they did not seem to him to possess any special interest.

DR. F. R. STURGIS said that he had seen four instances of chancre of the tonsils. The first was the one occurring in the boy at Bellevue Hospital, which had been described in the paper. Of the others, one occurred in a man, and two in women. The inflammatory attack was quite well marked, except in one case, in which all the symptoms were of a subacute character. In this the ulceration was quite superficial, but in the others it was well marked. The most important point in the diagnosis, he thought, was the ulceration of the preauricular and postauricular glands, and particularly of the former. This was a prominent characteristic in all the cases that he had seen. As regards the history, it was manifestly impossible to get a correct account of the origin of the trouble in the case of the women. The boy had been sufficiently frank to tell the story. He did not think chancre of the tonsil at all a common condition, and as it might be mistaken for other troubles, it was well to make the differential diagnosis as clear as possible. Between this initial lesion and gummatous infiltration of the tonsil there was a strong similarity; but the main point of difference would be found in the condition of the glands.

DR. L. DUNCAN BULKLEY thought that one of the most important points of the paper, which he regarded as of exceedingly great practical interest, was that it called public attention to another place in which the initial lesion of syphils was liable to occur. It had not been long since syphilis had been regarded as exclusively a venereal disease; so that to be affected with it was always a matter of reproach. Now, however, this was no longer the case, since we were beginning to learn in how many different ways the poison of syphilis might enter the system. Such a paper as this was, therefore, of great practical importance, as indicating to the general practitioner a source of danger in a situation in which he would probably not otherwise have thought of looking for it. As far as he could remember, he thought that he also had seen four cases of chancre of the tonsil. One was a particularly striking and touching case, occurring in a lady, who became affected with a papular syphilide without her family physician suspecting the nature of the trouble. She was thirty-two years of age, and of unblemished character. She was en-

gaged to be married to a man in the town in Connecticut where she resided, and it was undoubtedly from kissing him that the disease had been contracted. When seen by Dr. Bulkley in October, 1876, there was a well-marked chancre of the tonsil, with enlarged ganglia, and she stated that the tonsil first became affected in the preceding August. Subsequently the case proved to be one of the very worst that he had ever met with in all his experience with syphilis, disfiguring its unfortunate victim for life. Not long afterwards he was treating a lady for syphilis, who had been recently married, and it came to his knowledge that her husband was the very man who had given the first lady syphilis, the engagement having been broken off in consequence of this. During the present year the man himself had been under his care, suffering from very severe bone syphilis; and altogether he considered this one of the most interesting groups of cases that he had ever met with.

Dr. W. C. Jarvis said that he thought there was more dread of chancre occurring in the mouth than there was any necessity for, since the parts were constantly bathed with a stream of mucus and saliva all the time pouring through the œsophagus into the stomach, and thus preventing a lodgement of the virus. This was undoubtedly the reason why chancre of the tonsil was so rarely met with.

Dr. Taylor said, in reply to Dr. Otis, that he was well acquainted with the varieties in the appearances often presented by chancre in different parts of the body; but in the tonsils he did not believe that there was the same variation as in most other locations. The peculiar formation of this organ seemed to him to render a certain amount of hyperæmia and thickening inevitable when it became the seat of syphilitic infection. But even if the true nature of the trouble were not immediately recognized, much harm would not result to the patient, since it was now generally accepted that the right time to begin antisyphilitic treatment was when the outbreak of secondary symptoms occurred. He agreed with Dr. Sturgis that the intensity of the symptoms occurring in connection with chancre of the tonsil varied in different instances, and that the cardinal point in differentiating this from gummatous infiltration was the condition of the glands. This, taken in connection with the history and the concomitant conditions present, would leave little room for uncertainity. In regard to Dr. Jarvis's criticism, he would say that, in spite of the washing of mucus and saliva, the crypt-like follicles occasionally detained the syphilitic virus until infection had been accomplished. Hence it was well to be on the watch for its possible occurrence.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, May 27, 1882.

The President, R. F. Weir, M.D., in the Chair.

Dr. C. T. Poore read a paper on

OSTEOTOMY FOR ANKYLOSIS AT THE HIP-JOINT.

(See page 666.)

Dr. A. C. Post said that the case referred to by Dr. Poore in his paper was that of a young man upon whom he operated many years ago in the New York Hospital for ankylosis following morbus coxarius, which occurred in childhood. He divided the bone and brought the limb down into a good position, and the case seemed to promise well, but within one or two days after the operation the limb became enormously swollen, discolored, and the patient died of gangrene. The operation was performed below the lesser trochanter, and at the autopsy it was found that the gangrene was caused by the hooking of the femoral vessels over the projecting part of the upper segment of bone.

The President remarked that gangrene after osteotomy at the lower end of the femur had occurred in two cases within the last two years.

Dr. J. C. Hutchison thought that removal of a wedge-shaped piece of bone was unnecessary, because the osteotome itself makes a wedge-shaped opening, and when the bone is straightened the opening is closed, and in the operations which he had performed he had found it quite sufficient. He thought that the methods adopted and advised by Dr. Poore were such as were usually approved of by surgeons of the present day. In ankylosis of rheumatic origin, the head and neck of the bone being intact, Adams's operation (through the neck) should be performed, because being nearest the centre of motion, the formation of a movable joint here allows more freedom in the movements of the limb. If, however, the rheumatic arthritis is attended with large nodular deposits of new bone around the neck, this operation is inappropriate. The advantages of the operation below the trochanter (Gant's) had been well stated by Dr. Poore, and he thought that all surgeons would agree with the author of the paper that this operation was preferable in strumous cases, in which there is more or less destruction of the head of the bone, and a large proportion of cases requiring operation belong to that class.

He had divided the upper end of the femur three times. On one patient both bones were divided simultaneously, and the patient was subsequently treated by simple extension with a weight and pulley. This patient was shown to the Society. In the other case the patient was kept in bed for two weeks only, and extension was made by the weight and pulley. At the end of this time, when the immediate effects of the operation had subsided, he was put upon crutches, the sound limb being elongated by a high shoe, so as to suspend the diseased limb and allow it to make extension by its own weight, and also to be moved at the point of section, with the view of obtaining a false joint, using the weight and pulley at night. Union, however, took place in this case. The advantages of this method were that the patient was vastly more comfortable, while the weight of the suspended limb gave all the extension necessary, and an artificial joint is more likely to be formed, if this is desirable, than if the patient is kept in bed longer. Dr. Poore was to be congratulated in being able to overcome adduction without resorting to myotomy.

Dr. Poore remarked that the only two cases in which a false joint had remained for much length of time were those reported by Barton, in which motion continued for six years, and the case reported by Dr. Sands, in which motion continued for two years. Dr. Walton, of Pittsburg, in one case divided the bone, as did Dr. Sayre, between the trochanters, and the same history followed, that is, motion for a time, and then an abscess

would form, and the patient would be worse. After recovering from this somewhat, he would begin with passive motion, and the last record was that the bone at the point of motion was becoming ankylosed. There was no case on record, so far as he had been able to find, in which a permanent false joint had been formed. Dr. Poore thought the fatal cases, as a rule, followed section of the bone after ankylosis from hip-joint disease. At least this had been the fact within the last twelve years. Previous to that date the operations were done through a very large wound, and he thought that those cases should hardly enter into the statistics.

NEWS ITEMS.

WASHINGTON.

(From our Special Correspondent.)

HEALTH MATTERS IN CONGRESS.—Mr. Riggs, from the Committee on Public Health, reported back, with an adverse recommendation, House Bill No. 2885, to amend an Act entitled "An Act to prevent the introduction of infectious and contagious diseases into the United States, and to establish a National Board of Health," which was laid on the table, and the accompanying report ordered to be printed. Mr. Riggs stated that he was instructed by the Committee to report the following resolution, with the recommendation that it be referred to the Committee on Appropriations, and it was so referred:

Resolved, That the Committee on Appropriations of this House be, and they are hereby instructed to include in the sundry civil appropriations for the year ending June 30, 1885, the following items:

"For the Contingent Epidemic Fund, to be at the disposal of the President, and to be expended at his discretion, the sum of $200,000, including the unexpended balance of previous appropriations, amounting to $115,000.

"For the support of the National Board of Health, the following sums:

"For pay and expenses of the members of the Board, and for the investigation of questions affecting the public health, including the study of other diseases than smallpox, cholera, and yellow fever, $18,000.

"For rent, fuel, postage, telegraphing, printing, and all other miscellaneous expenses, $2500.

"For disbursing agents, clerks, and messenger, $4500, amounting in the aggregate to $25,000."

The effect of this action, if agreed to by the House and approved by the Senate, will be to leave U. S. quarantine matters in the hands of the Marine-Hospital Service, where it naturally belongs, and give the Board something to do in the way of miscellaneous investigations into the causes of disease and kindred subjects.

BERLIN.

(From our Special Correspondent.)

THE KOCH FESTIVAL.—The banquet of welcome given to Dr. Koch and his companions in recognition of their distinguished achievements and their return from Egypt and India, took place on May 13, in the spacious Winter-Gardens of the Central Hôtel. About six hundred physicians, civil as well as military, professors, State physicians and practitioners, gathered around the long row of tables. The assembly was also honored by the presence of Mrs. Koch and her daughter, who watched the proceedings from the balcony, surrounded by the ladies of distinguished members of the Committee.

The members of the Commission, Dr. Koch and Staff-surgeons Gaffky (Prussian Army) and Fischer (German Navy), wore the high war decorations conferred upon them by the Emperor, which the German Crown Prince had personally presented to them on the third day after their arrival. It is a remarkable fact, that the decorations were then for the first time given to medical men on the black ribbon, which has been heretofore reserved for active combatant officers, and further, that the Emperor himself, the day before his intended departure for Wiesbaden, received the Commission in ceremonial audience. Therefore, Professor Dubois-Reymond, who at the banquet had the honor of proposing the health of His Majesty, was right in laying stress upon the Emperor's lively and active interest in the development of art and science, adding that the peaceful era of the united Empire could not be better inaugurated than by remarkable deeds in this direction.

Prof. v. Bergmann, as President of the Committee, proposed the health of the Commission. It was not the peerless gallantry and self-devotion he wanted to praise—virtues as well exhibited by those who once undertook to study the typhus fever in Silesia, as by those who dissected plague-corpses in the mouldy huts of Wetliauka—virtues common to the profession. It was not more the momentary success which merited the highest praise in our science. "What we want to acknowledge to-day is your mode and manner of working, your undaunted assiduity, your unparalleled painstaking diligence, and last but not least, your scientific methods, cautious, critical, severe against yourself and your pupils." Surgery in particular, he said, was under obligations of gratitude to a man who, in antiseptics, had finished the work of Lister, like Harvey finished the discovery of Ambroise Paré.

DR. CONRAD KUESTER then, in the name of the practising physicians of the metropolis, welcomed the Commission and dwelt upon the practical consequences of their discovery; he went perhaps a little too far in assuming that in the future the work of the physician might be exclusively prophylactic. PROF. VIRCHOW, therefore, could not avoid warning his auditors against drawing too precipitately practical conclusions; but from a merely scientific point of view, he thought it well worth mentioning that the discoverers of the bacilli of cholera and tuberculosis had reconquered for the physician (the old master of all sciences belonging to "physics") a vast territory, which for a long time had been usurped by the botanist. He further dwelt upon the extraordinary and well-merited honors conferred upon the Commission, honors which he claimed were reflected upon the whole profession and which, he thought, were calculated to raise its authority as well as its self-esteem. In conclusion, he mentioned in a most spirited and humorous way his first meeting with Dr. Koch, who then was still a "Kreisphysicus" in a small country town (Wollstein).

After the reading of addresses from the "Gesellschaft für öffentliche Gesundheitspflege," and the "Verein für innere Medicin," by Professors Hirsch and Leyden,

ROBERT KOCH rose to make a reply. He did not find anything extraordinary, he said, in the whole enterprise for a man who, like himself, during twelve years was accustomed to deal with the germs of all kinds of infectious diseases, although the death of Dr. Thuillier might show that such expeditions were not altogether without danger. He likewise did not find anything extraordinary in the discovery of the cholera bacillus, which, sooner or later, would have been made out from necessity as a ripe fruit of the well-trained and exact *methods*. But he was gratified to find some acknowledgment of the merit in the development of these well-acting methods. He was well aware that his discovery would not contribute very much to the improvement of therapeutics, but he believed that his experiences in Egypt and India would allow him to make some practical propositions concerning the prevention of cholera, and that, perhaps, if only the governments concerned would agree upon his plan, *it might be possible to restrict the disease to its motherland—India*.

Words of such vast significance, on an official occasion, from the lips of a man of Robert Koch's reserve and modesty, deserve our highest attention. Careful readers of the reports sent from Egypt and India will remember a somewhat dark and obviously abbreviated passage about the mode of cholera importation studied in the quarantine harbors. This passage, together with the fact that the third report was not published at all, allows the conclusion that the German government is in possession of most important positive propositions about the effective prevention of cholera importation, which are not yet ripe for publication. The success of such measures would guarantee to our countryman a position among the greatest benefactors of mankind. For such a merit even the extraordinary honor of a public donation (of 135,000 marks) by a legislative Act just sanctioned by the German Diet seems only a poor equivalent.

The series of toasts was concluded by Dr. Lassar, who drank the health of Mrs. Koch, now united with her husband after painful months of sorrow and uncertainty.

LONDON.

(*From our Special Correspondent.*)

THE CLINICAL SOCIETY.—At the last meeting of the Clinical Society MR. WILLIAM ANDERSON read notes of a case of *Pyelo-lithotomy*. The patient was a young man, aged twenty-three, who had suffered for nine months from attacks of pain, in the left lumbar region, and hæmaturia, brought on by physical exertion. The urine was always free from pus and calculi. On admission to the hospital nothing could be detected on physical examination of the bladder or lumbar region. The urine contained blood-corpuscles and crystals of uric acid. After a month, however, tenderness and pain were felt in the left loin, and a local fulness accompanied by an increase in the area of renal dulness. An operation was performed about a month later. The kidney was exposed, with complete antiseptic measures, by an oblique incision parallel with the eleventh rib. A stone was detected in the pelvis of the kidney both by digital examination and acupuncture. This calculus was reached by an incision through the wall of the pelvis without damage to the renal parenchyma. It was seized with a pair of forceps, and after some trouble dislodged and removed. It weighed sixty grains when entire, and consisted mainly of oxalate of lime. Since the operation nearly forty calculi have been expelled. Excluding from present consideration all cases of nephro-lithotomy complicated by the presence of a lumbar sinus or in which an abscess has been previously opened (as in Mr. Morrant Baker's case in 1874), this example may be enumerated as the eighth on record. The operations have been completely successful in seven and followed by a fatal result within twenty-four hours in one, in which the kidney on the affected side was the seat of abscess and the opposite organ was extremely diseased. In no instance did any permanent fistula result, the urine ceasing to drain through the wound after the lapse of an interval ranging from eighteen hours to eighty-one days. The operative procedures differed principally in the treatment of the kidney. In five cases the stone was reached by division of the healthy renal tissues, and in two was removed through an aperture made in the duct. The term pyelo-lithotomy was proposed as a name for the operation now described, to distinguish it from the procedure in which the stone is extracted through a renal incision, and to which the name nephro-lithotomy more properly belongs.

MR. RICKMAN GODLEE did not think there was much danger from hemorrhage when the renal parenchyma was incised.

SIR ANDREW CLARK spoke of the medical interests of the case, and suggested that the diet or nutrition was at fault.

MR. HENRY MORRIS spoke at some length, and also endorsed the opinion that hemorrhage from the renal substance was readily stopped by elastic compression, as Mr. Marcus Beck had pointed out.

DR. FINDLAY read a paper on the sequel to a case of *aortic aneurism involving the ascending part of the arch in a woman aged about forty*. The disease had been attended with regurgitation through the aortic orifice.

MR. GOLDING BIRD read a paper on *hernie en bursæ*, and DR. FREDERICH TAYLOR related a case of foreign body in the larynx removed by laryngotomy. The body was a piece of mutton bone which had remained in the larynx below the glottis for three months.

DR. DE HAVILAND HALL asked how it was that no attempt had been made to remove the piece of mutton bone by means of the laryngeal forceps.

DR. COUPLAND narrated two interesting cases of foreign bodies impacted in the air-passages. One was a case of syphilitic caries of the base of the skull, in a woman who had died suddenly from asphyxia due to a piece of necrosed bone having fallen from the base of the skull into the larynx. A second case was that of a boy who had swallowed, inadvertently, a piece of mutton bone, which choked him and got into the bronchi, where it set up consolidation of the right lower tube of the lung. The bone was expectorated some months later, and the signs of pulmonary disease soon disappeared.

YELLOW FEVER NOTES.—Sanitary Inspector Burgess, U. S. Marine-Hospital Service, stationed at Havana, in

his weekly abstract of bills of health issued at that port for the week ending May 24th, says there have been thirteen deaths from yellow fever during the week. He inspected thirteen vessels, and fumigated three bound to U. S. ports—one, the Spanish bark "Eugenia," bound to Philadelphia, loaded with bones, hair, hoofs, horns, old metal, and old railroad iron, was regarded by him as in a very unsanitary condition, although he fumigated and disinfected the vessel and cargo as far as practicable.

Four vessels were inspected at the Cape Charles quarantine station during the past week, and all found to be in good sanitary condition; they put into Hampton Roads to await orders, and were loaded with sugar.

STATE MEDICAL SOCIETY MEETINGS.—*The Indiana State Medical Society* will hold its annual meeting at Indianapolis, on Tuesday, June 10th.

The Ohio State Medical Society will hold its annual meeting on the same day at Columbus.

The New Jersey State Medical Society holds its one hundred and eighteenth annual meeting at Cape May on June 10th.

The Maine State Medical Association also meets on Tuesday next.

The Massachusetts State Medical Society meets at Boston on Wednesday, June 11th.

The Rhode Island State Medical Society holds its annual meeting on Wednesday, at Providence.

The Michigan State Medical Society holds its nineteenth annual meeting at Grand Rapids on June 11th.

M. PASTEUR ON THE PROPHYLAXIS OF RABIES BY VACCINATION.—At a meeting of the Académie des Sciences on Tuesday last, M. Pasteur read an important communication on Rabies. It contained a detailed account of his experiments, made with the help of his pupils, MM. Rout and Chambellan, in order to arrive at a method of attenuating the virus of rabies. This long looked-for result M. Pasteur believes to be realized. If the virus of rabies be taken from a mad dog, and passed through the tissues of a monkey, and afterwards from monkey to monkey, its virulence is much modified. Dogs, rabbits, and guinea-pigs, inoculated with this modified or attenuated virus do not contract rabies. Neither does inoculation by trephining provoke the disease. The virulence of the virus of rabies is increased when passed from rabbit to rabbit, or from guinea-pig to guinea-pig. This virus, injected into the veins of dogs, provokes a more violent form of rabies than ordinary virus of rabies (*rage des rues*). In order to communicate this excessive virulence to the virus, it must be passed several times through the tissues of a rabbit or a guinea-pig. This is necessary in both cases, either of attenuation, from successive transmissions from monkey to monkey, or in that of the naturally weaker virus of rabies. M. Pasteur concluded by saying that he has succeeded in considerably simplifying vaccination for rabies, and at the same time rendering the animals exempt from illness. In a short time hence, he will communicate to the Académie des Sciences a completed and detailed account of his experiments. M. Pasteur has written to M. Faillères, Minister of Instruction, requesting him to appoint a commission to judge of the value of his experiments. The dogs rendered exempt from rabies by his method of vaccination will be placed at the disposal of its members. M. Faillères has appointed the following as members of the commission: M. Béclard, Dean of the Faculty of Medicine; M. Paul Bert, Membre de l'Institut, and Professor of General Physiology at the Science Faculty; M. Bouley, Membre de l'Institut, and Professor of Comparative Pathology at the Natural History Museum; Dr. Villemin, Clinical Professor at the Military and Medical Pharmaceutical School; Dr. Vulpian, Membre de l'Institut, and Professor of Comparative and Experimental Pathology at the Paris Medical Faculty; M. Tisserand, Conseiller d'Etat, State Director of the Agricultural Department.—*British Medical Journal*, May 24, 1884.

THE ELEVATION OF PROFESSOR FRERICHS TO THE RANK OF A NOBLE, has been received with the highest satisfaction by the Berlin medical press, and the profession at large. When he appeared at the Clinic the day after it had been made known, a very warm ovation awaited him. In acknowledging the compliment, he observed that he was quite aware that the distinction was appreciated not merely on personal grounds as related to himself, but also in relation to the profession of which he was a member. Conferring this rank upon professors is quite a recent occurrence in Prussia, the celebrated surgeon Bernhard von Langenbeck having been the first so honored in recognition of his services in the Danish war. A year later, Ranke, the famous historian, was raised to this rank on his seventieth birthday. So long ago as 1866, Dr. Lauer, the personal medical attendant of the Emperor, was so honored; and last year, at the request of the Crown Prince, the great physicist Helmholtz received the promotion. He commenced life as an anatomist and army surgeon; so that of the five persons who have been thus ennobled, four belong to the medical profession.—*Medical Times and Gazette*, March 29, 1884.

BABY-FARMING IN NEW JERSEY.—The State Board of Health of New Jersey has recently had occasion to investigate cases of sickness and death occurring within a few weeks in an institution known as a Sanitarium, near Hammonton, Atlantic County. It is a place for the reception of foundlings. There have been received since January 15th twenty-five infants, and twenty-three are dead. They were all buried, without certificate of death or undertaker, in a small lot near the house. The person in charge of the house is a female physician, who had not registered under the laws of the State. She claims to be conducting a charitable institution, and her prospectus has the endorsement of many excellent clergymen and laymen. The condition of a part of the premises is not good. All the children were bottle-fed. The case is being investigated by the coroner, and the developments, medical, dietetic, insanitary, moral, etc., are peculiar.

DR. C. C. FITE has recently resigned the secretaryship of the State Board of Health of Tennessee. This step was taken in order to devote his whole time to the practice of his profession.

THE UNIVERSITY OF PENNSYLVANIA.—At a meeting of the Board of Trustees, held on June 3d, Dr. William

Pepper was elected to the Professorship of The Theory and Practice of Medicine, rendered vacant by the resignation of Dr. Alfred Stillé.

VIRCHOW ON TRICHINOSIS. — PROF. VIRCHOW has written to the newspapers to express his opinion that the danger arising from trichinosis in German pork is "infinitely greater" than the peril of an epidemic from the American hog, and that, to be consistent, the Imperial Government, which has forbidden the importation of all sorts of American pork, should not allow swine-rearing in Germany.

PROF. S. D. GROSS.—At a special meeting of the Alumni Association of the Jefferson Medical College the following resolutions were adopted:

Whereas, The Alumni Association of the Jefferson Medical College has learned with feelings of heartfelt sorrow and regret of the death of its honored President, Professor Samuel D. Gross.

Resolved, That in his death the Association has lost its most eminent member—one whose constant endeavor it was to promote the best interests of his Alma Mater, to establish throughout the land her reputation as a great school of medicine, and to unite in a bond of common brotherhood her alumni.

Resolved, That as the most illustrious alumnus of his Alma Mater, he has conferred honor upon his country and his profession as a learned author, a teacher unequalled in his ability to impart instruction, and a practitioner whose comprehensive knowledge and sound judgment distinguished him as the good physician and great surgeon.

Resolved, That he has left an imperishable record of an honorable career, characterized by an indefatigable industry, integrity of purpose, noble ambition, devotion to the elevation of the standard of his profession, and by all that could contribute to greatness of his calling.

Resolved, That, distinguished by those amiable qualities of heart and that genial disposition which endeared him to his fellow-men, we found in him always a kind friend and a wise counsellor.

Resolved, That we tender to the bereaved family our deepest sympathy in the great loss they have sustained.

NOTES AND QUERIES.

BACILLUS TUBERCULOSIS.

To the Editor of THE MEDICAL NEWS.

SIR: As an encouragement to those who are trained in the use of the microscope, but who refrain from employing it in the search for the tubercle bacillus, I write to say that I have succeeded perfectly by the aid of your recent editorial giving Fränkel's method. I had failed after repeated efforts whilst using magenta by the formula advised by Drs. Gradle and Voltmann; not necessarily, however, owing to a defect in their directions. With an excellent objective (Nachet, No. 7), I do not find a condenser essential. The error which the beginner is apt to make is by employing too low a power. With the "aniline water," treated with fuchsine as a staining agent, the colors being taken out by alcohol weakly acidulated with nitric acid, I had the best results. The preparations were kept seven minutes in the staining fluid, which was heated in a test-tube just before using, and ten or more in the alcohol. I did not find restaining essential.

In my experience, a jointed, rod-like fungus, of the same length as Koch's bacillus, and which I have several times seen, is apt to be taken for the true bacillus.

The beginner should have good, prepared specimens of the bacillus for comparison. Such were sent to me by Col. Rion, of this State, and they proved very useful.

Truly yours,

F. PEYRE PORCHER, M.D.

CHARLESTON, May 28, 1884.

TRACHEAL STENOSIS.

To the Editor of THE MEDICAL NEWS.

SIR: THE MEDICAL NEWS for May 17, in its report of the proceedings of the American Laryngological Association, contained a report of a paper which I read, and which was based on three cases of stenosis of the trachea (probably of specific origin), treated by enormous doses of iodide of potassium or sodium, gr. 90 to 480 daily, with gratifying results after ordinarily large doses, gr. 30 to 60 daily, had utterly failed.

Your reporter says, with reference to the first case: Dr. Ingals recommended iodide of potassium *very highly* in this kind of trouble; the patient died, his decease being attributed to asthma, etc.

This places the matter in a wrong light, leaving the reader to suppose that I thought the patient died of asthma, which was not correct; and second, that I *highly* recommended a common remedy for a common disease.

What I really said was that the paper was merely suggestive, illustrating what might be accomplished in *some proper* cases by giving *very large doses* of a remedy which I believe should usually be given in small quantities.

Further, he states: "In the second case this acted so favorably that there had been no return of the severe symptoms *which were at no time urgent*, etc." [The italics are my own.]

This would lead the reader to suppose that it was a trifling case which was but slightly modified by treatment. On the contrary, the patient had been in great distress for many weeks, and for several days before the heroic measures were adopted and for a number of days afterward, he had been in imminent danger. Subsequently his dyspnœa had been relieved as the result of the treatment, and he had been able to resume his work.

Referring to the last, which was the most interesting case of the lot, because in it the progress of the recovery was accurately watched by the laryngoscope, and a perfect cure resulted, your reporter says only this: "In the third case it was necessary to perform tracheotomy." This would lead the reader to suppose that *during ineffectual* treatment the operation became necessary, whereas, the history clearly shows that tracheotomy was done before the large doses (which constituted the interesting feature of the paper) had been given, and that while the remedy was being given according to the method under discussion the obstruction speedily disappeared, although it had previously resisted all ordinary treatment.

If these large doses are recommended in any case, it is important that the remedy should be *largely* diluted and its effects carefully watched.

Very truly yours,

E. FLETCHER INGALS, M.D.

CHICAGO, May 30, 1884.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 27 TO JUNE 2, 1884.

WRIGHT, J. P., *Major and Surgeon.*—Directed to perform, temporarily, in addition to his other duties, those of Medical Director, Department of the Missouri.—*Par. 2, S. O. 107, Headquarters Department of Missouri*, May 28, 1884.

MIDDLETON, PASSMORE, *Captain and Assistant Surgeon.*—Granted leave of absence for one month on surgeon's certificate of disability.—*Par. 2, S. O. 107, Headquarters Department of Missouri*, May 28, 1884.

BAILY, JOS. C., *Major and Surgeon.*—Now on leave of absence, is relieved from duty in Department of Texas, and ordered to report to Commanding General Department of the East for assignment to duty at Fort Monroe, Va., to relieve Lieutenant-Colonel Charles Page, Surgeon, U. S. A., on July 1, 1884, from duty at that station.

LIEUTENANT-COLONEL PAGE, on being relieved by Major Baily, will proceed to Fort Leavenworth, Kansas, and report to Commanding General Department of the Missouri, for assignment to duty as Medical Director of that Department.—*Par. 12, S. O. 125, A. G. O.*, May 29, 1884.

CONGENITAL DEFORMITY OF HAND; COMBINED ECTRODACTYLISM AND SYNDACTYLISM.[1]

BY ALFRED C. POST, M.D.,

VISITING SURGEON TO THE PRESBYTERIAN HOSPITAL, NEW YORK.

NOVEMBER 3, 1883, C. W. J., a healthy and otherwise well-formed young man, twenty years of age, was brought to my clinic with a congenital deformity of his left hand, as seen in the cast herewith presented. There was absence of the index and little fingers, and of the corresponding metacarpal bones. The thumb, the middle, and the ring fingers were well developed, and their movements of flexion and extension were not deficient in force. The two fingers were webbed together throughout their whole length; from the normal position of the commissure, as far down as the middle of the second phalanges, the uniting medium was of moderate thickness, consisting of the dorsal and palmar integument, with loose cellular and adipose tissue. The terminal extremities of the two fingers were joined together immovably throughout their whole thickness, and the middle finger, being considerably longer than the ring finger, was necessarily bent, and could not be straightened. A single, very wide nail covered the dorsal surface of the terminal extremity of the two fingers, having a superficial longitudinal groove to indicate the normal line of separation of the fingers.

The patient being etherized, I performed the following operation. I divided the cutaneous portion of the web with a scalpel, and then divided the nail and the deeper tissues with a cutting bone-forceps. There was a small amount of bony union of the terminal phalanges. After the bleeding had been arrested, I was able to bring the dorsal and palmar integument together on the side of each finger with fine silk sutures, from the position of the normal commissure, about half way down to the ends of the fingers. I wound straps of adhesive plaster around each finger separately, and then secured the two fingers with a roller-bandage to a padded dorsal splint, extending from the ends of the fingers above the middle of the forearm.

November 5.—I removed the splint, and applied fresh strips of adhesive plaster around each finger. I then covered the fingers with lint, secured by a roller-bandage. As the splint was irksome to the patient, I did not, at this time, reapply it.

10th.—The edges of the wound had receded. The cuticle had separated from the cutis. I removed the sutures, and dressed the fingers separately with strips of India-rubber adhesive plaster.

17th.—A portion of the integument of the ring finger has sloughed, and a small portion of the base of the middle phalanx is bare. The middle finger is doing well.

19th.—Directed fingers to be dressed with carbolized vaseline, and reapplied dorsal splint.

December 5.—The middle finger is almost entirely cicatrized. The ring finger is in a much better condition than at the time of the last report, and the healing process is going on favorably.

29th.—The middle finger is healed. The commissure between the middle and ring fingers is entirely healed. The ring finger is nearly cicatrized. The middle finger now projects about twelve millimetres beyond the ring finger.

January 5, 1884.—Cicatrization complete. Splint discontinued.

12th.—Middle finger has become somewhat distorted since it has lost the support of the splint, which was accordingly reapplied to-day.

19th.—The shape of the finger is improved. Continued splint.

Soon after the last date, the patient discontinued his attendance.

The result of the treatment was entirely successful in overcoming the syndactylism; but the middle finger had been so long distorted by its abnormal fusion with the ring finger that it is somewhat doubtful whether it will ever assume its perfect normal configuration.

The combination of ectrodactylism with syndactylism in the case which I have presented is a rather unusual one; but Holmes, in his work on the surgical treatment of the diseases of childhood, gives an illustration of a case resembling it, except that the fusion of the two fingers was not so complete, each of the fingers having a separate nail. The thumb also was more widely separated from the fingers, standing out at right angles with the carpus. Both hands and both feet were affected with syndactylism.

In connection with the case which I have reported, I will present a few facts relating to the two varieties of malformation, which usually occur separately, but which in this patient were combined.

Ectrodactylism is more rare than syndactylism. The deficiency may involve a single finger or the thumb, or several or all the fingers may be wanting, or may be in a state of very imperfect development. It may involve both hands, or may be confined to one. Fort refers to thirty-two cases in which the situation was indicated. Both hands were affected in twenty of these cases, the left hand in eight, and the right in four. In most cases only the fingers were wanting. In five cases the metacarpal bones also were absent. Some of the carpal bones are occasionally wanting. When the thumb and little

[1] Read before the New York Surgical Society, May 27, 1884.

The terms ectrodactylism and syndactylism are derived from the Greek δαχτυλος, a finger, with the prefixes εχτρωσις, abortion, and συν, together.

finger are present, and the other fingers are absent, the hand has been compared with a lobster's claw.

Many cases of congenital absence of the thumb have been reported; in some of these the radius has been absent, or imperfectly developed. The little finger is rarely wanting. Out of thirty-seven cases, the little finger was entirely wanting only in three, and in these the thumb and all the other fingers were absent. In two other cases the distal phalanx of the little finger was wanting.

Partial or entire absence of fingers has occurred in different generations of the same family, as in a remarkable instance reported in the *Edinburgh Medical and Surgical Journal* for 1808, p. 252. As a general rule, when some of the fingers are wanting, those which exist have their full normal mobility and strength.

Syndactylism presents itself in two forms, viz.: congenital and acquired. The congenital form may affect one or both hands; in the majority of cases both are affected. Sometimes the thumb and all the fingers are fused together; sometimes all the fingers without the thumb; any two or three may be joined together. When both hands are affected, different fingers may be involved in the two hands. The deformity is sometimes, but not often, hereditary. It is occasionally, but not usually, complicated with ectrodactylism or other deformities.

Syndactylism may be complete or incomplete. The complete form involves the whole length and thickness of the fingers, which have a common investment of skin, with perhaps a slight furrow indicating the normal line of separation. In the incomplete form, the uniting medium is comparatively thin, consisting of normal and palmar integument, with more or less intervening cellular and adipose tissue. This uniting medium may extend the whole length of the fingers, or only a part of their length; it may be quite narrow or of considerable breadth. It is generally broadest and thinnest toward the distal extremities of the fingers. The fused fingers are usually of normal size and structure. When they are very firmly bound together, they are apt to be smaller than in their normal state. There may be separate nails for the fingers, or a common nail of great breadth may extend over two or more fingers. The coalescence of the fingers may be almost complete, even involving the bony phalanges. The superficial palmar arch has been known to extend below the level of the normal commissure of the fingers. Bernier, of Besançon, reports a case in which a child was born with the thumb and four fingers all confounded, so as to constitute but one body of the full breadth of the hand, and having a single nail at the extremity of the dorsal surface. The five toes were in like manner joined together. Dessaix reports a similar case.

Acquired syndactylism is the result of adhesion of two or more of the fingers by means of cicatricial bands following burns or very severe mechanical injuries. Many cases of syndactylism, whether congenital or acquired, are capable of being cured by a surgical operation. Where the fingers are all fused together in a common mass, as in the cases reported by Bernier and Dessaix, little or no benefit, as to appearance or function, is to be expected from treatment. In those cases of complete fusion in which only two or three fingers are involved, there is a better chance of success from an operation. Velpeau and Verneuil object to an operation where there is bony union. Fort objects to an operation where the fusion does not extend beyond the proximal phalanges, on the ground that in such cases the deformity and functional disturbance are but slight. When the thumb is fused with the index finger, an operation is specially important to the function of the thumb. When all the fingers are joined together by a cutaneous web, their separation is of less importance to function than to appearance, and, even in such cases, serious difficulties are sometimes encountered in the attempt to separate them. The general principles of treatment are the same in congenital and acquired syndactylism.

There is a difference of opinion among surgeons as to the most eligible time for an operation in congenital syndactylism. Chelius recommends waiting until the age of puberty. Nélaton, Maisonneuve, and Chassaignac recommend an early operation. Verneuil prefers the age of three or four years. In acquired syndactylism in children, Verneuil advises a delay of one or two years after the occurrence of the deformity.

Until a comparatively recent period the operations which were performed for the relief of syndactylism, were successful in a very limited degree, except in cases in which the uniting medium was broad and thin. The older surgeons contented themselves with a free division of the uniting medium, and the interposition of lint, bandages, or plasters between the fingers until the wounds were healed. The consequence was the healing by granulation and cicatrization, and the reunion of the lateral surfaces of the fingers with each other to a considerable extent below the normal commissure, and for some time after the healing of the wounds the persistent contraction of the cicatricial tissue caused the newly formed commissures to descend more and more toward the distal extremities of the fingers. In cases in which the uniting medium is thin and broad, this retrocession of the commissures may be prevented by great care in the dressing of the wounds. After incising the web or uniting medium, the edges of the integument of each finger should be closely approximated by strips of adhesive plaster throughout their whole extent, great care being taken to make firm pressure as close as possible to the newly formed commissure, which should be a little higher up than the normal separation of the fingers. The dressings should be frequently repeated, the parts being washed each time with a solution of mercuric bichloride, eight grains to the pint. The growth of granulations should be restrained by the frequent application of nitrate of silver, and the wound should be sprinkled with subnitrate of bismuth. When there is an obstinate disposition to the growth of granulations from the surface between the fingers, in addition to the means which have been mentioned, an elastic band may be applied between the fingers, and its two ends attached before and behind to a bracelet which is worn around the wrist. By this means any required

degree of pressure may be maintained to repress the growth of granulations. In cases in which any considerable difficulty in overcoming the deformity is apprehended, it will be advantageous to establish one interdigital space completely before attempting the establishment of another. In this way pressure can be more advantageously maintained to approximate the edges of the wounds, and a more abundant supply of material can be obtained to close the vacant spaces on the borders of the fingers.

When the uniting medium is very thick and narrow, advantage will be derived from making the incision encroach a little on the dorsal and palmar surfaces of one of the fingers, so as to leave a more ample supply for the other. By this means the edges of the wound on the second finger may be healed by first intention; and although the healing of the other wound will be retarded, there will be no tendency to the reëstablishment of lateral union between the two fingers. The healing of the wound which is left to granulate may be accelerated by skin grafting. Occasional instances of congenital syndactylism have occurred in which there was a small hole through the uniting medium just below the position of the normal commissure, the hole being lined with integument. In such cases after division of the uniting medium from the perforation to the distal extremity, and separate dressing of the fingers, there is no tendency to coalescence, the skin lining the perforation being an effectual barrier to the descent of the commissure. The following case illustrates this condition as well as the coexistence of ectrodactylism and syndactylism. On the 23d of August, 1848, I saw a female child of Mrs. F., two months old. It was the first child of her parents, and was in good health, but deformed as follows: Right hand, thumb and index finger perfect, the other three fingers have each only the first phalynx, and they are all webbed together throughout their whole length. The mother states that when the child was born a cord passed from the little to the ring finger over their truncated extremities, and that this cord was spontaneously ruptured at the age of three weeks, soon after which it disappeared. A little rudimental knob was also over the united ends of the middle and ring fingers. This also dropped off. Left hand, thumb perfect, each of the fingers has but two phalanges, the distal phalanx being deficient. The middle and little fingers each have a small pedunculated knob at the extremity. The index and middle fingers, and the ring and little fingers, are webbed at their distal extremities, but free towards the hand, so that a probe can be passed between them and moved freely. The middle and ring fingers are closely webbed together throughout their entire length, with the exception of a small perforation, barely admitting the passage of a probe, at the level of the normal commissure. The right foot is in its normal position, but the distal phalanx of the great toe is wanting. The left foot at birth presented a slight degree of varus, but, by the persistent manipulations of the mother, the position has been nearly rectified. The toes of the foot are all perfect.

On the 23d of August, I separated the index from the middle finger of the left hand, and the ring from the little finger, bandaging the fingers separately, and on the 11th of September, I separated the middle from the ring finger. The wounds all healed favorably, and the separation of the fingers was complete.

The favorable results of the operation in this class of cases in which there is a perforation between the fingers, have led surgeons to make an artificial perforation where the uniting medium was entire, and to maintain the opening by passing through it a metallic wire and leaving it in place until the circumference was cicatrized. When the web is broad and thin, such perforation is unnecessary. When it is narrow and thick, it is very difficult to secure cicatrization of the margin of the hole, and the attempt gives rise to a considerable amount of irritation. Upon the whole, I am not disposed to regard the method as one of great practical value.

Maisonneuve treated a case of syndactylism by including the uniting medium throughout its entire length between two wedges acted on by screws, so as to make pretty firm pressure, on the principle of Dupuytren's enterotome. It occasioned but little pain or inflammation. The section was complete about the twelfth day, when the fingers were found to be healed. The separation of the fingers was perfect and permanent.

Velpeau treated syndactylism by incising the uniting medium throughout its whole extent, and applying three sutures at the commissure, one in the middle and one on each side. Verneuil modified the practice by applying sutures along the whole lateral surfaces of each finger. Follin, Theguier, Morel Lavallée, and Vidal de Cassis, report successful cases treated in this way.

Fort gives a description of a variety of plastic operations devised by different surgeons for the cure of syndactylism.

The process of Letter is as follows: A triangular flap of dorsal integument with its base at the commissure, and its apex at the articulation of the first and second phalanges, is cut and reversed on the dorsal surface of the hand. The web is then divided throughout its whole length, and the flap is brought down and attached by suture to the palmar integument. Morel Lavallée modified this process by making a palmar flap as well as a dorsal one, truncating their apices, and uniting by suture.

Ths process of Dieffenbach consists in dividing the uniting medium, dissecting the skin from the subjacent parts on the dorsal and palmar surfaces, and then gliding the flaps together and uniting them by sutures on the side of each finger.

The process of Decés consists in forming the commissure from the web. The fingers being separated as widely as possible, the surgeon seizes the web longitudinally between the blades of a dissecting forceps, the points of the forceps corresponding with the normal position of the commissure. An assistant holds the forceps while the surgeon cuts on each side from the free extremity of the web to the commissure, leaving the web attached at the commissure. The fingers are separately dressed, and heal by granulation and cicatrization, while the web sinks and forms

a commissure. Decés had complete success with this plan in a case of syndactylism from the cicatrix of a burn, in a child of eight years. The commissure appeared entirely satisfactory thirty months after the operation.

A very ingenious operation for the cure of syndactylism was devised by the late Dr. J. Kearney Rodgers, of this city. I cannot give the exact date of this operation, and I am not certain whether Dr. Rodgers published an account of it. But I have a record of a case in which I repeated the operation in 1846, and I have a strong impression that Dr. Rodgers had performed the operation many years before that time. The operation consists in making a longitudinal incision on the palmar surface of one finger and on the dorsal surface of the other, and dissecting from the adjacent parts a dorsal and a palmar flap, the palmar flap covering the side of the finger from which the dorsal flap was taken, and the dorsal flap covering the side of the finger from which the palmar flap was taken. In this way the lateral surfaces of the fingers were covered with sound skin, and the wounds left to heal were transferred to the palmar surface of one finger and the dorsal surface of the other.

In the case in which I performed the operation there was partial sloughing of the flaps, troublesome secondary hemorrhage, and a considerable amount of inflammation. The healing process was retarded, and was not completed until about three months after the operation. The fingers were well separated from each other, but their motions were not very free, when the child was taken from the city.

One of my colleagues in the New York Hospital undertook the performance of Dr. Rodgers's operation on an adult patient, but made the singular mistake of making the dorsal and palmar incisions on the same finger, leaving that finger only half covered with integument, while the adjacent one had a superabundant covering. The result was very satisfactory. The wound of the finger which was amply supplied with integument healed very promptly; that of the other finger healed very slowly, but there was no raw surface on the other finger to which it could adhere, and the syndactylism was completely cured.

M. Fort gives an accurate description of Dr. Rodgers's operation, illustrated by woodcuts, but he makes no mention of Dr. Rodgers. He ascribes the operation to M. Didot, of Liege, in Belgium. Didot published an account of the operation in the *Bulletin de l'Acad. de Bruxelles*, in 1850, tom. ix. No. 5. Sedillot says that Didot reported successful cases in 1845. There seems to be no reason to doubt that Dr. Rodgers was the originator of this operation, and that he performed it a number of years before Didot. It does not appear certain whether Didot had become acquainted with Dr. Rodgers's operation. If he had not, it is remarkable that he should have devised an operation agreeing with that of his predecessor in all its minute details.

Nélaton claims to have anticipated Didot in this operation.

In *The Medical Press and Circular* of April 25th, 1866, Barwell describes an operation which he performed with success for the cure of syndactylism. He divided the uniting medium close to the side of one finger, so as to leave ample integument to cover the other finger; and he cut a flap from the side of the gluteal region to cover the denuded side of the first finger, binding the forearm and hand to the body until the flap had united with the finger.

The most valuable collection of facts in relation to ectrodactylism and syndactylism is to be found in a monograph entitled, *Des Difformités Congénitales et Acquises des Doigts, et des Moyens d'y Remédier*, par le Dr. J. A. Fort. Paris, 1869.

A NEW METHOD OF PREPARING EGG-ALBUMEN.

BY EDWARD T. REICHERT, M.D.,
DEMONSTRATOR OF PHYSIOLOGY AND EXPERIMENTAL THERAPEUTICS, UNIVERSITY OF PENNSYLVANIA.

UP to within very recent years the white-of-egg was considered to be an almost pure egg-albumen; consequently, the old method of Hoppe-Seyler for preparing egg-albumen directs that the white-of-egg be finely cut with a pair of scissors and mixed with an equal volume of water; the mixture is now shaken briskly in a flask until quite frothy, and is then allowed to stand. In a few moments the froth, having adherent the fibres of the fine membranous network of the white-of-egg, will collect on the top of a turbid yellowish fluid. The solution is now strained through linen and filtered, and the filtrate dried at a temperature not above 40° C. Before drying, it can be further purified of most of its salts by dialysis.

Recent researches of Lebonte and Goumœns (*Journ. de Pharm.*, s. 3, xxiv, 17), Sherer, and others, show that the white-of-egg is not a proximate albuminous principle. The former investigators found that dilute or glacial acetic acid gives a decided precipitate with the white-of-egg, while Sherer observed that if a small quantity of dilute acetic acid was added to the solution of the white-of-egg and the liquid largely diluted with water a flocculent precipitate occurred; furthermore, that this precipitate was soluble in a small quantity of potassic nitrate and sodic chloride, and was coagulable. It has since been determined that the body thus precipitated is a globulin, consequently a more recent method of preparing egg-albumen is gradually to add dilute acetic acid as long as a precipitate occurs. The mixture is now filtered and dried, or dialyzed before drying, as in Hoppe-Seyler's method.

Wurtz (*Ann. Chem. Phys.*, 3, xii. p. 27) gives a method which is represented to give pure albumen. The white-of-egg is freed from its membranes as in Hoppe-Seyler's method and filtered, the filtrate is mixed with a small quantity of basic plumbic acetate, which produces an abundant precipitate. The precipitate is washed and is then brought to the consistence of thick paste. CO_2 is passed through, which decomposes the plumbic albuminate, forming plumbic carbonate, which is suspended in the liquid, while the albumen in a free state remains in solution. The solution is filtered through a paper previously washed with dilute acid. The filtrate is treated with a few drops of sulphuric acid and then cautiously heated to 60° C., until it begins to show turbidity; the first

flocks of the albumen precipitated carry down the whole of the plumbic sulphide. The filtrate is perfectly colorless and is evaporated at 40° C., the residue consisting of pure soluble albumen. (*Watt's Dict.*)

The recent method of Hoppe-Seyler (*Phys. und Path. Chem. Analyse*, 1883, p. 270) directs that, after separating the membrane and filtering, the solution is purified by saturation with magnesic sulphate at 20° C., the precipitate is washed by a saturated solution at this temperature; the filtrate is now precipitated by saturation with sodic sulphate at 20° C., the precipitate is collected and repeatedly dissolved in water and reprecipitated by sodic sulphate. The sodic sulphate is now removed from the precipitate by the addition of a large amount of distilled water, and the precipitate then collected and dried at between 40° and 50° C. This gives a tolerably salt-free albumen.

These methods I have entirely superseded for general laboratory purposes by the use of carbonic acid water or the common soda-water of commerce. My method is to free the white-of-egg of its membrane as in Hoppe-Seyler's method, but before filtering to add an equal volume of carbonic acid water. This causes a considerable amount of flocculent precipitate, which settles readily or which can be quickly filtered off. The filtrate is perfectly clear, passes with comparative rapidity, and is slightly alkaline in reaction; it gives no precipitate with dilute or strong acetic acid, or by the further addition of CO_2. Very little of the CO_2 remains in the solution in a free condition, but seems to be combined with the free alkali in the white-of-egg. This solution, which is now free from globulin, can be dried at a temperature of about 40° C., or can be freed beforehand of most of its salts by dialysis. The quantity of carbonic acid water necessary will of course depend upon the amount of gas in solution, and the only rule is to add sufficient to precipitate entirely all of the globulin.

This method of preparation possesses great advantages over the foregoing, inasmuch as the albumen is quickly prepared and in a condition sufficiently pure for general laboratory work; the process is very simple; and there is not the objection of the contamination of so foreign an element as acetic acid. Since the white-of-egg contains alkaline carbonates as natural constituents, and as the CO_2 seems to form such salts, the introduction of the gas can scarcely be considered in any way objectionable.

The carbonic acid water is now readily obtained in siphon bottles at a very nominal cost, is always ready for use, easily handled, and, when added to solutions in proper proportion, immediately saturates them without giving rise to the excessive annoyance experienced in albuminous solutions by the formation of bubbles while passing a stream of gas through them. These advantages in the use of the carbonic acid water over the gas have caused me to substitute it for some time in testing, and I have found it to act most admirably in the precipitation and preparation of various proteids, which I will shortly report. If it is desirable to have the carbonic acid water free from the contaminations of our river waters, *distilled water* can readily be charged with the gas.

A CURIOUS CASE OF PERSISTENT REFLEX SPASM OF THE DIAPHRAGM.

BY A. L. RANNEY, M.D.,

PROFESSOR OF APPLIED ANATOMY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL

A CASE which I desire to bring before the notice of the profession was lately sent to me by Dr. L. M. Bingham, of Burlington, Vt., for diagnosis and suggestions as to treatment. Her history was as follows:

Miss E. W. Unmarried. Aged forty-four years. Her father died of cancer, complicated with phthisis, at the age of seventy; her mother died of heart, disease at the age of thirty-five. She has three sisters living, all of whom are "delicate and of a nervous temperament." Two sisters died of Bright's disease. One niece of the patient had chorea of a severe and persistent type.

As a child, the patient was afflicted with "extreme nervousness," but never had any marked symptoms of chorea. She menstruated at thirteen years, but was irregular until she reached the age of thirty years, since which time the menstrual function has been normal. Insomnia became developed as a marked symptom at the age of twenty years. It has persisted ever since; but with varying degrees of intensity. From youth she has been subject to more or less tremor of the hands, and has lately noticed that excitement markedly increased it. The tremor stops during sleep and does not cause her much inconvenience during the day. Neuralgic pains occasionally shoot into the hands and fingers, and are often experienced in the shoulders, back, and left side.

Four years before the date of my examination, she was attacked with *paroxysms of hiccough*. These have persisted throughout the past four years. The attacks come on in paroxysms which last from ten to sixty minutes. They are often so severe as to cause vertigo and symptoms of asphyxia. *They almost invariably follow movements of the upper extremities.* For that reason all manual efforts have been avoided for some years. The sweeping of a room will throw the patient into a severe paroxysm of hiccough. Sewing is rendered impossible for the same reason. Dressing the hair almost invariably induces an attack. Movements of the head, trunk, or legs seem to exert no influence upon the patient of a similar character.

Of late, neuralgic attacks have become more frequent and severe. The eyes have been affected with neuralgic pains of a severe type, and also the shoulder of the left side.

On examination, no loss of muscular power was detected by me in either hand by means of the dynamometer. The condition of her body in respect to sensations of touch, pain, and temperature was tested and found to be normal. No painful points (the puncta dolorosa of Valleix) were detected over the seat of the neuralgic attacks. Pressure made over the spinous processes of the vertebræ produced no pain *except at one point.* This corresponded to the situation of the fourth, fifth, and sixth cervical segments of the spinal cord. Here the patient suffered marked pain on pressure and the skin was markedly hyperæsthesic. The patient stated, in reply to my

interrogations, that this region had been the seat of a continuous "aching sensation" for the past four years. The superficial and deep spinal reflexes were normal. Coördination was performed perfectly in both the upper and lower extremities. The pupils were normal and responded perfectly to light and visual accommodation.

The condition was evidently one of abnormal excitability of the lower cervical segments of the cord, associated with general neurasthenia. The fifth cervical segment gives origin to filaments which enter into the formation of both the brachial plexuses and the phrenic nerves. The phrenic nerves arise from the third and fourth segments as well. The case appears to justify the conclusion (based upon anatomical data), that the activity of the lower cervical segments (necessary to movements of the arms and hands) produced in adjacent segments of the cord an abnormal irritation of the cells associated with the physiological function of the phrenic nerves—hence the diaphragmatic spasm.

The patient was burnt with the benzine cautery apparatus over the cervical and dorsal segments of the cord, and ergot and the bromides were ordered to relieve the local congestion of the cord that probably exists. This treatment had previously been tried for a short time with marked benefit, but had been discontinued when the symptoms exhibited amelioration. The effect of the continued use of the cautery has yet to be determined.

156 MADISON AVENUE, May 18, 1884.

MEDICAL PROGRESS.

POISONED ARROWS.—DR. R. CAMPBELL, Civil Surgeon of Tezpore, has, the *Indian Medical Journal* reports, made some experiments with the poisoned arrows taken from the Aka after the raid at Balipara last November. He feels certain that the poison used is dried aconite-root, pounded and fastened on the arrow's head by a gum. As a rule, the shafts and the heads are separate pieces, so that, in trying to pull the arrow out of the wound, the head is left in. He recommends the hypodermatic injection of liquor ammoniæ, two parts to one of water; and syringing out of the wound with solution of nitrate of silver, forty grains to the ounce, as the most useful treatment.—*British Medical Journal*, April 26, 1884.

NITRITE OF AMYL IN MIGRAINE.—DR. BIANCHI has caused the instantaneous disappearance of this troublesome affection by making the patient inhale three drops of nitrite of amyl placed on a handkerchief. The subject was a woman who suffered from this neurosis at each menstrual epoch. It is well known that nitrite of amyl acts by paralyzing the muscular fibres of the small arteries, and that its action is specially exerted on the cerebral vessels, and that local congestion is the consequence of this congestion.—*Revue de Thérap.*, May 15, 1884.

TREATMENT OF TETANUS.—DR. MARAGLIANO, *à propos* to a case of tetanus cured by isolation and large doses of chloral, draws the following conclusions in an article published in *La Salute*:

1. The patient should be placed in a dark room, which should be noiselessly entered every fifteen minutes in order to give food or drink.

2. The ears should be so stopped that the patient shall have absolute rest, and the floor should be carpeted.

3. Every three or four hours the patient should take some bouillon, an egg, and some white wine.

4. All pain should be calmed by administering belladonna, conium, or chloral, the last being preferable.—*Revue de Thérap.*, May 15, 1884.

ULCERATION OF THE TRACHEA AND OPENING OF THE INNOMINATE BY A TRACHEAL CANULA.—At the meeting of the Société Médicale des Hôpitaux, on April 11, M. D. HEILLY presented the specimens from this case. Tracheotomy had been performed during an attack of croup. The case went on well, with the exception of slight fetor of the wound. After the second day the canula was removed for several hours every day, and on the sixth day was removed altogether. On the eighth day the child was apparently well. On the twelfth day profuse hæmoptysis set in, and death soon followed. At the autopsy it was found that the anterior wall of the trachea had been ulcerated by the stylet of the canula; this also involved the innominate. Deep ulcerations of the trachea after tracheotomy are very rare. Cases of ulceration of the œsophagus have been reported, but opening of the innominate seems to have been observed only twice, by Howse.—*Gaz. Hebdom.*, April 18, 1884.

HYSTERECTOMY FOR FIBROUS TUMOR COMPLICATED BY HYDRONEPHROSIS.—At the meeting of the Société de Chirurgie, on April 2d, M. POZZI reported this case. The patient was a woman, forty-four years of age, who had had a tumor of the uterus for eight years, and for five or six months had had a fluctuating tumor in the right side, which, after an exploratory puncture, was diagnosticated as hydronephrosis. After the puncture hectic symptoms came on, the patient weakened rapidly, and got into a very bad condition. Pozzi punctured the cyst again, and drew off a large amount of purulent fluid. On the next day he performed hysterectomy, and found an enormous uterine fibroma, which he separated by two elastic ligatures, one at the cervix, the other at the broad ligament, whilst a third was applied on the right side of the tumor, where it was adherent to the hydronephrosis cyst. On this side the pedicle was enormous. The pedicle at the broad ligament was left in the abdomen. The hydronephrosis attained its original size in about five weeks, when another puncture, and washing with sublimated water, caused it to disappear entirely.—*Gaz. Hebdom.*, April 18, 1884.

EXTIRPATION OF THE UTERUS THROUGH THE VAGINA.—On March 8th PROF. PERUZZI performed this operation in the hospital at Lugo. The patient was thirty-four years old, and had cancer of the cervix, with supravaginal infiltration. The Billroth operation was performed. On April 18th the patient was doing well.—*Gazz. Med. di Torino*, May 5, 1884.

LAPAROTOMY FOR VOLVULUS.—DR. AMBROSI recently performed this operation successfully at the Monte Giorgio Hospital.—*Gazz. Med. di Torino*, May 5, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 14, 1884.

THE PREVENTIVE INOCULATION OF HYDROPHOBIA.

THE cable has recently brought to this side of the Atlantic the news that M. PASTEUR had discovered, isolated, and cultivated the virus of hydrophobia, and made protective inoculations with it. Immediately, the medical journals repeated this announcement, and the public prints gave it a warm welcome, and spoke of it as a great achievement, full of promise for suffering humanity. Medical men, too, have been interviewed by newspaper reporters, and, on the strength of the meagre and imperfect abstract which the cable had furnished to the daily papers, have expressed an unqualified approval and endorsement of Pasteur's views.

We have delayed our comment until after receipt of the paper of M. Pasteur, read before the Academie de Medécine, May 20. This is now at hand, and demands, we think, a little different handling from what the previous account has received, and of a sort which the possibility of Pasteur being misrepresented in this would have hardly warranted.

The points of M. Pasteur's paper are as follows: The protective power of inoculations with attenuated virus is an established fact. The virus of rabies is attenuated by passing it by successive inoculations through the monkey. It is increased in virulence by similar passage through the rabbit or guinea-pig. In either case it can then be communicated to the dog in its modified state of virulence, either greater or less than original, producing in one case certain death, in the other protection. The plan of action proposed is to take the virus from a rabbit dying after inoculation at a period somewhat longer than the shortest (which he assumes to indicate the greatest virulence), and inoculate this successively in other rabbits, inoculating in the first instance from it, and in turn from each of the series of rabbits, a dog. The effect, Pasteur asserts, will be to render the dog refractory to the rabies which occurs "on the streets," that is, to the natural as contrasted with artificial inoculation.

Pasteur next asserts: "By inoculations of the blood of animals, I have succeeded in simplifying very much the operation of vaccination, and in procuring in the dog the most refractory state." He expresses the hope that he will be able, by the application of his theory, to secure immunity in animals after they have been bitten. Finally, he says he would have been happy to have published this announcement only after his conclusions had been "controlled" by some of his colleagues, but for the lack of sufficient material, and that he has asked the Minister of Public Instruction to appoint a Commission to test the results of his experiments.

The scientific and humanitarian importance of this announcement is very great, and, being coupled with the positive assertion of Pasteur that it furnishes an "infallible" means of preventing and curing hydrophobia, there is no wonder that numberless persons have applied to M. Pasteur and expressed their willingness to be inoculated with the modified virus which causes rabies. But, as the reaction which follows upon the dispelling of an illusion is all the greater the higher the illusion has raised the hopes of mankind, it may be worth while to call the attention of our readers to certain facts which ought not to be out of mind for an instant when weighing the claims of this promising announcement.

In the first place, it ought not to escape the notice of the careful observer that what Pasteur proposes in his paper is not a strict application of his own theory. He claims that passage through monkeys weakens the virus, while passage through rabbits strengthens it; and then he proposes protective inoculations with virus taken from rabbits, which is more virulent, not virus from monkeys, which is attenuated. In the second place, it will be noticed that he does not assert that he has in this way secured immunity against rabies a single time. He says he has *simplified the operation of vaccination by inoculations with the blood of animals*, and so has produced the most refractory state. He has not made, and does not dare to suggest, the application of his theory to the protection of human beings. And for animals he only hopes its application may prove effective to save after a bite has been inflicted. The request for the appointment of a Commission to test the value of his hopes, indicates that M. Pasteur is willing to have it tested, but it would be a mistake to suppose it adds

to its claim upon the acceptance of others *before the test is applied.*

There are other serious flaws in the argument of this paper, but we have not time now to point them out. We pass to some more general considerations as to the position claimed by M. Pasteur and his supporters in relation to this subject.

M. Pasteur has done a great deal to advance the study of what are called disease germs, but he has not had such confirmation of all his assertions as to warrant the acceptance of a strange statement from him before it has been tested and corroborated by others. In a variety of matters he has made extravagant claims of discovery, which have not borne the test of time. In regard to hydrophobia, it is not long since he made an announcement, as positive as this last one, which was very soon shown to be utterly erroneous. Even if this were not the case, one might look with some distrust upon the statements now made in regard to the curious weakening and strengthening of the virulence of the assumed virus of rabies by respective inoculations into rabbits and monkeys. In regard to this matter, the assertions of Pasteur lack the essentials of scientific accuracy. We have not yet been told the reason for calling rabid the dog from which he got the virus he first used. No one but Pasteur has seemed to show that this virus resides where Pasteur says it does—in the brain especially, and with peculiar virulence. On the contrary, as Pasteur does not appear to know, many other parts of the body, solids and fluids, have been inoculated with as great degree of success as he claims for his inoculations with the virus taken from the brain, where he says it can be gathered in "perfect purity." Further, he, and those who follow his lead, find it convenient to ignore utterly the inoculation-experiments of such excellent observers as Hertwig, Wright, Galtier, Paul Bert, and Colin, which show that, whatever it may be which is produced by the inoculations of brain substance, this does not succeed as invariably in the hands of others as it does in those of Pasteur; that, when it does succeed, the result does not differ from what can be effected with many other matters from various parts of a subject supposed to have rabies, or from similar parts of subjects beyond suspicion of it; and that the result is probably a form of septicæmia, not rabies at all.

For a few years Pasteur, whose attention was accidentally attracted to this subject in the Academie de Médecine of Paris, has been experimenting upon it. If he has ever produced what can with security be called rabies by his inoculations, the record of these experiments is wanting. If he has a well-defined idea of what rabies really is, he has never yet made it public. On the contrary, he has formulated in another place a sort of definition which is elastic enough to permit him to affirm anything produced by his inoculations to be what he was after. "Nothing," he has said, "is more varied than the symptoms of hydrophobia. Each case of hydrophobia has, so to speak, its own special ones" (*les siens propres*).

This is not the way to get at a truth so obscure as the nature of hydrophobia. And we think it a duty to warn our readers against too hasty an acceptance of this recently cabled announcement of Pasteur, or too sanguine a trust in the saving grace of a virus attenuated by passage through monkeys. It may be all so; but this newcomer has such a questionable appearance that we may not be accused of being too sceptical if we await the report of the commission appointed to consider the subject.

TUBERCULOSIS OF THE TONSILS.

TWENTY-TWO years ago, Virchow wrote: "The explanation of the fact that tubercle of the tonsils has not been observed, I am unable to give. Possibly it is merely due to want of sufficient examination. Even if tubercle should be found, it must occur so rarely that these organs may be said to possess a sort of immunity." Since that time, tubercle of the tonsils has been many times seen and described as occurring in connection with tuberculosis of the throat and soft palate. But as this affection is relatively rare in these parts as compared with other structures, the dictum of Virchow has been generally received as true. This more or less complete immunity of the tonsils is, from the standpoint of the doctrine of infection, a very remarkable fact. Consisting of a tissue, in which elsewhere tubercular processes develop by preference, situated at the entrance to the organs of respiration and alimentation, and subject constantly to morbid processes of all kinds, the tonsils ought to be peculiarly liable to tuberculosis.

DR. FRITZ STRASSMANN, *Virchow's Archiv*, May 5, 1884, at the suggestion of Cohnheim and Weigert, conducted in the Pathological Institute at Leipsic, last year, a series of investigations with a view to determine the question as to the occurrence of tubercle in these structures. His results are wholly at variance with the views hitherto held.

In bodies showing tuberculous changes, he found tubercle in the tonsils to be extremely common—not less than 13 times in 21 cases. It was present as disseminated miliary deposits of small, or even the smallest, size, and in varying distribution—a single preparation sometimes containing a great number, while sometimes several sections had to be examined before any were encountered. These tubercles are rich in giant-cells, and resemble the deposits found in the lymphatic glands. Somewhat larger caseous masses were also seen, but very seldom. Bacilli occurred in small numbers and the sur-

rounding tissues showed very little change. The condition resembled closely that of the kidneys in urogenital tuberculosis, or in acute general miliary tuberculosis, and was in striking contrast to the spreading caseation and destructive deep ulceration of the tonsils, seen when the tuberculous process invades them from the throat or palate. The affected tonsils were of normal size, or atrophied or hypertrophied as the case might be, but showed no characteristic macroscopic appearances.

Among the 21 cases were 15 of tuberculous disease of the lungs; of these, tuberculosis of the gut was present in 5; of the larynx in 5; of the pleura in 2; of the liver and kidneys in 3; finally, of the tonsils in 13.

In contrast to this group were six cases in which the tuberculosis had not proceeded from the lungs. In two of these—one a case of acute miliary tuberculosis having its origin in caseating bronchial glands, the other of tuberculosis of the suprarenal capsules—the lungs were, it is true, the seat of a recent secondary tuberculosis. In the four others, namely, one case of tuberculosis of the intestine, one of the testicle, and two of the serous membranes, the lungs were wholly free. In none of this second group of six cases was tubercle found in the tonsils.

In so far as the cases observed warrant a conclusion, it may be stated that tubercle of the tonsils is a very frequent accompaniment of tubercular disease of the lungs; and since the former condition was only present in those cases in which infection by means of the sputa could occur, and in none of the others, the probability that such infection is the cause of tonsillar tuberculosis becomes very great. Nothing was found that would in any way sustain the view that tubercle may occur as a primary lesion of the tonsils in consequence of the direct access of the infecting principle to their tissues. The condition described is altogether without clinical significance.

RUPTURE OF THE VAGINA IN ITS MEDICO-LEGAL ASPECTS.

FROM copies of the *Morning Herald*, published at Dunedin, New Zealand, recently received, we learn of the trial of a practitioner named Parry, for having "killed and slain" a woman in labor, and of his conviction with sentence to four months' imprisonment. There seems to have been a most indecent and unjust haste in the judicial proceedings, for the offence with which he was charged was committed on the 28th of March, and Parry was tried, convicted, and sentenced on the 2d of April; and by this haste the voice of popular clamor was echoed rather than the calm utterance of justice. From the scanty evidence found in the paper, we gather that the doctor was called to a woman in labor, and, upon his first examination, ascertained she had a rupture of the vagina, and so stated to one of the women present; he seems to have given the patient chloroform to relieve her suffering, but resorted to no active interference, telling the husband that his wife would die. The two medical men examined for the prosecution, stated that death occurred from hemorrhage caused by the rupture, and that this was from external force. How they could know that external force caused the rupture, we do not understand, for the post-mortem was made a day after the woman's death, and the form of the injury does not indicate its cause. The medical gentlemen who testified for the defence were very modest in their claims, merely stating that the vagina might be ruptured without external violence, and apparently were thus as far wrong one way as those for the prosecution were the other way, but both to the detriment of the prisoner. The evidence ought to have been that vaginal rupture in labor is in almost every case the result of uterine contractions; and generally, too, some tearing of the uterus is associated with the vaginal injury.

We are glad to see that a special meeting of the New Zealand Medical Association was held very promptly, at which it was unanimously resolved "That it is the opinion of the highest obstetrical authorities that nearly all cases of uterine and vaginal rupture depend upon pathological conditions, and have occurred in the most skilful hands." It was also resolved that a petition should be forwarded to the Governor, praying for a commutation of Dr. Parry's sentence. But why did not the Association simply state that the great majority of these injuries were spontaneous and not traumatic? Above all, why was not such evidence introduced at the trial? The judicial proceedings seem to us marked by shameful blundering—the court blundered, the counsel for the defence did not bring in the strongest evidence, the medical witnesses on each side blundered, and finally the jury completed the series of blunders. New Zealand justice proved itself in this case very prompt, but also very blind.

THE RECIPROCAL HEREDITY OF UTERINE MYOMATA AND PROSTATIC HYPERTROPHY.

DR. PAUL J. B. M. JOSSO has brought forward, in the *Gazette Médicale de Nantes*, some interesting statistics apparently showing a reciprocal heredity between uterine myomata and prostatic hypertrophy. He believes that a full study of the subject will perhaps lead to the announcement of this law: Myomatous degeneration of the uterus in the mother predisposes not only her daughters to this affection, but also her sons to prostatic hypertrophy, and, reciprocally, hypertrophy of the prostate in the father predisposes not only his sons to the same disease, but also his daughters to uterine myomata.

Certainly this is an important law if sufficiently numerous observations verify it.

One of the arguments suggested by Dr. Josso is that from embryogeny, and he seems to consider the prostate as the analogue of the uterus. But it is the prostatic utricle, rather than the prostate itself, which some embryologists have regarded as the analogue of the uterus; another argument against the suggested analogy is that the uterus is developed at a very much earlier period of embryonic life than the prostate. However, the question must be decided by clinical observation rather than by the history of intra-uterine formation.

SINCE December 14, 1881, DR. ALEXANDER, of Liverpool, has operated in twenty-one cases of prolapse, or of posterior displacement of the uterus, by shortening the round ligaments. The results have been generally very satisfactory. The operation has been performed by others—among these are Dr. Imlach, one of the surgeons to the Liverpool Hospital for Women, who has operated fifteen times in the last sixteen months, and Dr. Burton, another surgeon to the same hospital, who has operated six times.

The operation appears to be a reasonable one, not very difficult of performance, and, if its results prove permanent, one that is to be commended, for certainly posterior displacements and prolapse of the uterus, if at all chronic, while they may be palliated, or relieved at least temporarily, very often are most rebellious to cure.

SOCIETY PROCEEDINGS.

THE NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, May 19, 1884.

THE VICE-PRESIDENT, CHARLES A. LEALE, M.D., IN THE CHAIR.

DR. GASPAR GRISWOLD read a paper entitled

NOTES ON ALBUMINURIA.

Ever since the publication of Dr. Bright's views in 1827, until very recently, he said, the presence of albumen in the urine had been regarded as positive proof of disease of the kidneys. This position remained unassailed as long as dropsy and other symptoms existing in connection with the albuminuria pointed toward the kidneys; but since it had become almost the routine practice of many physicians to test the urine of nearly every patient consulting them, a change of opinion had occurred. This had also been due, to a considerable extent, to the observations of medical men engaged in making examinations for life insurance. The somewhat startling fact had thus been developed that albuminuria was sometimes found in persons who stated that they were in perfect health, and who had every appearance of being so. These persons might be divided into three classes: (1) those in whom the albuminuria lasted a long time, occasionally continuing for years; (2) those in whom it was transient; and (3) those in whom it was intermittent, appearing at certain hours of the day, and being lacking at others.

The question, therefore, arose, Was this kind of albuminuria merely functional, or did it indicate some slight pathological change in the kidney itself? Having given a brief description of the renal epithelium, he stated that under ordinary conditions it permitted only the constituents of normal urine, which were purely excretory, to pass through it; but if its integrity were interferred with in any way, it would allow the blood-plasma and peptones to pass to a greater or less extent into the urine. Peptones were considered by some high authorities to be always present in the urine when albumen was.

Among the conditions which he mentioned as liable to be accompanied by a certain amount of albuminuria were hysteria, anæmia (in which there was recognized epithelial degeneration), and the presence of certain substances in excess in the system, as the biliary principles and iodide of potassium. When the latter was taken in considerable quantities, not only albumen, but casts, were sometimes found in the urine.

It would seem, therefore, that there was a temporary degeneration of the renal epithelium which attended the excretion of large amounts of solid constituents by the kidneys. In speaking of food-albumen, he said that if the albumen of eggs were injected into the blood, it would not be assimilated, but might be recovered from the urine into which it passed. It was, therefore, thought that imperfectly digested albuminous food might perhaps give rise to albuminuria in the same way. Degeneration of the renal epithelium seemed, as far as he was able to judge, to be the cause of albuminuria in nearly all cases; and hence he thought that there could be little doubt that the albumen met with in the urine in apparently healthy individuals was really of renal origin. Slight disorders of all the other organs were sometimes met with, and he saw no good reason why they should not occur in connection with the kidneys also.

Dr. Griswold then gave an abstract of the literature referring to albuminuria in apparent health, and among the authors whom he quoted was Sir William Gull, who had not infrequently noticed albumen in the urine of anæmic young girls about the time of puberty. Moxon had reported in the *Guy's Hospital Reports* nineteen cases of albuminuria in children, without other symptoms, and all of them recovered. Dr. George Johnson had remarked that this kind of albuminuria was more apt to be present in the afternoon, and particularly after exercise, bathing, etc. It was especially likely to be met with in those who indulged in sea-bathing, and remained in the water until they were blue and shivering. Such a condition was, therefore, regarded as a warning of the danger of such practices. He also quoted from German, French, and Italian writers, and then referred to the article of Dr. Munn in the *New York Medical Record* for March 22, 1879, in which he reported twenty-four cases of albumen in the urine of persons applying for life insurance who were apparently in perfect health, in two of them there being casts also in the urine. All were rejected simply in accordance with the rules of the

insurance companies, although in every other respect the individuals were in good condition.

Thus, he continued, there were a large number of excellent authorities who agreed as to the presence of albumen in the urine sometimes in health, and a very considerable number of cases of this had now been accumulated. In regard to the occurrence of albuminuria in the anæmia of puberty, he thought Sir William Gull's position was well taken. As to the effect of exercise in producing albuminuria, Dr. Griswold said that he had himself made repeated examinations of the urine of twenty-four persons after running two or three miles, taking long and brisk walks, etc. In every instance the exercise was sufficiently violent to induce profuse perspiration, and it had usually been followed by a cold shower-bath, which, it had been claimed, was especially favorable to hyperæmia of the kidneys and albuminuria. In not one of these cases, however, was he able to detect the smallest trace of albumen in the urine.

He then related the case of a gentleman who applied for a policy in the New York Life Insurance Company. He appeared before the health examiner in the afternoon, and the urine that he passed at that time was found to be highly albuminous; in consequence of which he was rejected. This was in February. In the following month he was persuaded by an energetic agent to make application at another company, and when his urine was examined at this time it was found to be normal, in consequence of which he was accepted. The gentleman then told what his experience had been at the other company, when, of course, it was deemed necessary to make further examinations of his urine. On the 14th of March it was found to be entirely free from both albumen and casts; but on March 22d it was distinctly albuminous and abounded in both fatty and granular casts. Just before this last examination it was ascertained that he had been taking a boxing lesson, as had also been the case before the examination in the other company. The gentleman then consulted Dr. Janeway in reference to the condition of his urine, and the latter carefully examined his water twelve times without detecting the least abnormality. Dr. Janeway then inquired what he had been doing before passing the urine in which the albumen was found at the life insurance companies, and, learning about the boxing lessons, he made several examinations of urine passed in the afternoon after taking the lesson. The result was that albumen and casts were found in every specimen examined. The importance of one such case as this, Dr. Griswold thought, could not be exaggerated.

He next passed on to speak of the influence of food. The effect of eggs in producing albuminuria had been alluded to by a large number of authors, and with a view to test the correctness of such statements he had experimented very thoroughly on himself, repeatedly eating as many as six eggs at a meal, both raw and cooked in various ways. On no occasion whatever was this ingestion of egg-albumen followed by the presence of albumen in the urine, and the same had been true in the case of a number of friends of his whom he had induced to partake largely of the same diet. In one instance, it was true, the examination of the urine showed the distinct presence of albumen; but, on investigation, it was ascertained that albuminuria also existed in this case when no eggs had been eaten, so that it could not, of course, be attributed to this cause. The gentleman was a physician, who had not previously had any reason to suspect that he was the subject of albuminuria. Eighteen individuals were experimented on, a large number of eggs being consumed by each one of them, with the above result. In regard to the effect of anxiety or mental strain in the production of albuminuria, as claimed by Albutt, Dr. Griswold said that he had had no opportunity to verify the statement, but that he thought it was probably an exaggeration.

In conclusion, he said that he thought we were justified in believing that the kidneys might be the subject of slight transient disease, as was the case with other organs. This was perhaps more properly renal inadequacy than actual disease, and while it was sufficient to produce albuminuria, it was not sufficient to require any special treatment, or to cause any uræmia. He then mentioned the case of a young physician who for some years after an attack of scarlatina, which occurred in his youth, was the subject of albuminuria; from which, during all that time, he was never free in the daytime. For the last four or five years, however, no albumen had been found in his urine. He also mentioned the case of another physician who some years since was seized, at the same time with an ordinary cold in the head, with a sharp pain in the lumbar region. He attributed it simply to lumbago, but a medical friend having jokingly suggested that he might have contracted Bright's disease, he made an examination of his urine, when he found to his surprise that it contained not only albumen, but hyaline casts also. After five days, however, both the albumen and casts disappeared, and had never been found in the urine since. The pain in the back and albuminuria occurred five years ago. Dr. Griswold thought, therefore, that there was probably the same relation between such a cold with albuminuria and Bright's disease that there was between a slight hemorrhage and phthisis. Although such hemorrhages were sometimes undoubtedly the forerunners of phthisis, in many other cases they were not followed by any serious results.

DR. A. FLINT, SR., remarked that the paper opened up a subject of great interest and very considerable practical importance. In addition to the subject of albuminuria, however, he said he should like to hear that of urinary casts also discussed; as these seemed in many instances to denote, if not a purely functional disturbance, at least not a grave form of disease of the kidneys. This fact was certain, that in quite a number of cases albumen and casts were found in the urine without being accompanied by those symptoms which were ordinarily found in acute nephritis, and that, after persisting for a longer or shorter period, they entirely disappeared, leaving the patient in perfect health. These cases were by no means infrequently met with in practice, and the presence of the signs mentioned were very apt to lead the physician to make a prognosis which was not borne out by the subsequent history of the case. He then related the case of a young girl, fourteen years of age, in whose urine a slight amount of albumen, with casts, was found. There was nothing in her condition to call attention to the kidneys, and, indeed, she had no appearance of being ill in any way; so that no examination of her urine would have been made, had the father of the girl not especially requested

it in consequence of the fact that Bright's disease had carried off one or more members of his family. The albumen and casts continued in the urine for a considerable period, although there was never at any time a condition of ill-health, and then disappeared altogether.

DR. WM. H. WELCH said that every one who made many examinations of specimens of urine sometimes met with cases in which there was albuminuria, and yet in which there was no disease of the kidneys that was susceptible of proof, and but a very trifling disturbance, if any, of the health in any way. Sometimes medical students, who were very apt to make examinations of their own urine from time to time, were surprised and alarmed to find the presence of albumen in it. This had been the case with a student two days before, who was apparently in perfect health, but who had been working very hard. Dr. Welch then mentioned the case of a gentleman whose urine was found to contain a slight amount of albumen while he was suffering from some disturbance of digestion. He soon recovered from this, but for ten days or a fortnight the quantity of albumen steadily increased, until it constituted a fifteenth part of the bulk of the urine. At this time he was apparently in perfect health, and it was a noteworthy fact that the quantity of albumen in the urine had been the smallest when he was feeling the worst. In oxaluria and lithæmia, or whenever there were abundant urates in the urine, he thought, as a rule, that a slight trace of albumen would always be found if the urine were examined soon after being voided. Dr. Griswold's theory of the inadequacy of the renal epithelium in albuminuria seemed to him a plausible one, but he hardly saw how its correctness could be established. It was certainly a matter of importance to the profession in general to understand that an individual might be in apparently perfect health and yet have albumen in his urine, and he thought that in many cases even when there was some impairment of the health, it was very hazardous to make a diagnosis of Bright's disease. Personally, he would attach no importance to albuminuria alone, and in some instances even where this was accompanied with casts.

DR. E. G. JANEWAY said that he had had the good fortune to secure an examination of every specimen of the urine passed by a patient for an entire month. This was found to be normal in specific gravity and normal in quantity, and to contain no casts, except on one occasion, when a few hyaline casts were detected. It was, however, always loaded with albumen in the afternoon; though early in the morning and again at night it was entirely free from it. It was found to be albuminous after breakfast, although not before, and Dr. Janeway at first thought that the albumen was caused by the food which he ate; but he afterwards ascertained that it also followed other things besides eating, such as a sponge-bath, mental worry or excitement, etc. The patient was a broker, and at night, when the cares of the day were all over, he was always free from albuminuria. Cases were sufficiently common in which, while there was albumen in the urine, there was no demonstrable kidney-trouble, so that the finding of a moderate amount of albumen had come to be regarded as no proof in itself; but in this instance the urine was actually loaded with albumen. There was a marked transudation of serum, and it was apparently due, in great part at least, to nervous influence. The case referred to by Dr. Griswold in his paper, in which albuminuria was found after boxing, was still more remarkable. In this, mucous casts were found occasionally at other times, but after the boxing lesson there were always hyaline, and sometimes, granular casts also. In the morning and at night again, however, there were neither albumen nor casts. This case would seem to show, therefore, that it did not take so long for hyaline casts to form as had generally been supposed. After his boxing lesson, this gentleman always took a sponge-bath with alcohol and water, and the sudden check of perspiration would seem, he thought, to have some effect in producing the albuminuria and casts. The case was certainly one of special interest, and it was impossible to say at present what the results would finally be. It seemed also to enforce the lesson that a single examination was not sufficient to exclude the existence of albuminuria. Medical men could not be too particular in this respect. It was well to remember, however, that two or three specimens of urine might be free from all albumen and casts when the patient was in reality suffering from distinct disease of the kidneys. This was apt to be particularly the case with the granular contracted kidney.

DR. FLINT said that he should like to add a word in regard to one practical point. The impression was somewhat prevalent, he thought, that because there was albumen in the urine there was danger of uræmic poisoning; but uræmia might be developed without any albuminuria whatever, and the practical point to which he wished to call attention was that the probability of the occurrence of uræmia depended solely on the quantity of urea eliminated (which could be determined sufficiently accurately for all practical purposes by noting the amount of urine passed), and on the specific gravity of the urine.

DR. GRISWOLD, in closing the discussion, referred first to the matter of albuminuria being caused by partaking of albuminous food in excess. All the works spoke of its production by eating largely of eggs, but he had never once met with any statements of actual experiments or facts to prove this. He thought, therefore, that the point was not well established; his own experiments, so far as they proved anything, distinctly militating against its correctness. He then went on to say that it seemed to him that the evidence went to show that we did have mild affections of the kidneys, as well as of other organs. These cases of transient albuminuria, however, ought to be watched and carefully followed up, so that the condition of affairs might be reported ten, fifteen, or twenty years hence.

DR. DANIEL BROWN then presented

A SPECIMEN OF ACEPHALOUS MONSTER.

He said that he had been called to attend a woman who was taken suddenly in labor at the end of seven and a half months of pregnancy. When he arrived, a well-formed male child had just been born, but was still attached by a remarkably short and thick cord to the placenta, which was adherent to the uterine wall. The situation of the placenta was just above the pubes (low down on the left side), and on making an examination, he found that there was a second fœtus in the uterus. This was delivered in four hours, and proved to be the

acephalous monster exhibited. It was entirely enveloped in a very thick and strong membrane of its own, which gave it the appearance of an enormous kidney, and which was firmly attached to its body by sebaceous matter. There was no amniotic fluid. The cord in this instance was at least three times the length of the other, and there was an entirely distinct placenta, which was attached at the fundus. The monster was sent to Prof. W. T. Lusk, who exhibited it before the class at Bellevue, and made a partial dissection of it. This was afterwards completed by Prof. Wm. H. Welch. There was a small amount of brain tissue, and the development of the heart seemed to have been arrested at the second month; though the rest of the circulatory system was comparatively complete. One of the kidneys was merely rudimentary, but the other was well developed. The intestinal tract ended about one inch above the anus, which was imperforate.

Dr. Brown then entered into a discussion of the theory of the development and nutrition of this class of monsters, as set forth by Lusk, Turner, Flint, Jr., Dalton, Cazeau, Braxton Hicks, Playfair and other authors, and stated his conviction that there was a direct continuity of circulation in the mother and fœtus, in opposition to those who believed that the true acephalous fœtus was always dependent for its nutrition upon the presence of a normal fœtus, from which its blood-supply was derived, there being no direct communication between the fœtal and maternal vessels.

DR. WM. H. WELCH remarked that if Dr. Brown was not mistaken in his assertion that there were two entirely distinct placentæ, the specimen was of exceptionally great value. Those who regarded such monsters as dependent upon another fœtus, based the opinion mainly upon the following premises:

1. The rudimentary character of the heart.

2. The fact that it was always associated with another well-developed fœtus.

3. The continuity of the placentæ and the anastomosis of the umbilical vessels of both children.

So far as he was aware, no case had as yet been reported in which the existence of two absolutely separate placentæ was so well established as in this, although it was certainly to be regretted that the placentæ had not been preserved by Dr. Brown. He could not but think, however, that there must have been some sort of connection between the two, as no instance of an acardiac monster developing alone in the uterus had ever been reported, so far as he knew. The existence of two distinct placentæ in this case, if established, would strike a blow against the generally accepted view that there was no direct communication between the fœtal and maternal vessels, and that the change in the fœtal blood was effected by endosmosis.

DR. J. LEWIS SMITH stated that he had seen several acephalous monsters, some of which were not of a twin character, and some of which lived for three or four days. Only the upper portion of the cranium, however, was wanting in the instances which he had seen, and one of them occurred in the practice of Dr. S. S. Purple.

DR. PURPLE then gave an account of the case to which Dr. Smith had alluded, but said that he thought it was, perhaps, hardly admissible to quote it in this connection.

DR. WELCH replied that incomplete development of the cranium was not analogous to the class of cases in question, which are absolutely non-viable. Although they were generally called acephala, *acardia* was the correct designation for them, and, having in reality no heart, it was, of course, impossible that they should live for a moment after birth.

DR. BROWN, in closing the discussion, repeated the statement that the placentæ were perfectly distinct, and attached at different parts of the uterine cavity. He thought there could be no possible doubt of these facts.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 5, 1884.

THE PRESIDENT, FORDYCE BARKER, M.D., LL.D., IN THE CHAIR.

THE STATISTICAL SECRETARY, DR. F. V. WHITE, announced the

DEATH OF THOMAS C. CHALMERS, M.D.,

one of the founders of the Academy, who was born at West Galway, Saratoga County, New York, on the 18th of June, 1810. He was graduated from Union College in 1831, and from the College of Physicians and Surgeons, New York, in 1835. He died June 4th, of uræmia, resulting from cystitis and pyelitis. Dr. White also announced the death of another Fellow, Dr. G. Le Roy Newcomb.

THE PRESIDENT then announced

THE DEATH OF THE SENIOR EX-PRESIDENT OF THE ACADEMY, DR. WILLARD PARKER, AND OF HONORARY FELLOW, DR. S. D. GROSS.

In connection with their deaths, he said that it had occurred to him that it would be of interest to refer to one or two facts regarding the first members of the Academy. It was founded in 1847, over 37 years ago, and of the 118 original Fellows, 100 were now dead. 7 had died between the ages of 80 and 90 (the average age at the time of death being 83), 18 between 70 and 80, and 47 between 55 and 70. Among the eight ex-Presidents who had died, the average age attained was 78.5, and only two of them, Drs. Watson and Bulkley, had died under the age of 70. The present Senior ex-President, Dr. James Anderson, had passed his 86th birthday, in the full possession of all his faculties, and all the other ex-Presidents, so far as he knew, were still actively engaged in the practice of their profession. This length of life seemed to him very remarkable, and he thought that no parallel could be found in any other body of 118 men brought together, without selection as to probabilities of longevity. The longevity of medical men as a class, had been acknowledged to compare favorably with that of any other profession, notwithstanding the anxieties, the mental strain, and the irregular sleeping and eating to which they were, as a rule, subjected; but he thought it a reasonable matter to inquire whether the Academy of Medicine had not had a special influence on the longevity of these 118 men, by stimulating them to lives of activity, usefulness, purity, and temperance, while it fostered those social qualities, the exercise of which was conducive to good health, and repressed emotions and passions that were unfavorable to length of days.

Having referred in feeling terms to the recent affliction of Dr. Samuel T. Hubbard in the death of his son, who had just entered the profession, and who lost his life from disease contracted in the discharge of his duties as one of the house staff of Bellevue Hospital, he went on to pay a tribute to the memory of the late Dr. Willard Parker, who had been elected President of the Academy in the year 1856, and who was at the time of his death its senior Ex-President. For many years, he said, he was the most prominent and conspicuous man in the profession in New York, both as a surgeon and as a general practitioner, and with the exception of Dr. Benjamin Rush, who lived a hundred years ago, no one ever wielded so commanding an influence over the community in which he lived, both medical and outside of the profession. His most distinguishing characteristic was quick perception, an insight which gave him an intuitive power of at once grasping the essential features of the cases which were presented to him, and discarding those which were unimportant and merely incidental. As a practitioner he was exceptionally successful, and this he attributed in no small degree to the stimulating and tonic effect of the cheerfulness, confidence, and hope with which he inspired his patients. It was also due in part, no doubt, to the practical value of hygienic and general directions which he was careful never to neglect to give. Dr. Barker said that he would not pretend to make any estimate of his rank as a great surgeon, but what contributions he had made to surgical literature had always been of an useful and admirable character. He had no doubt that his paper advocating operative interference in abscess of the appendix vermiformis had been the means of saving a very large number of lives, and he himself felt personally grateful for it, since, in consequence of it, two patients of his own had been successfully operated upon.

Passing on to speak of the late Prof. Gross, he mentioned that he had been elected a Corresponding Fellow of the Academy in 1851, and an Honorary Fellow in 1876. No man of the present age, he said had made such a reputation as a great surgical writer and teacher, and none had received so many honors from learned societies and institutions all over the world. His work had been simply monumental, and it had been continued up to the very last. He did not believe that there was any instance of a medical man at seventy-eight years of age writing such a remarkable paper as that on "Lacerations of the Female Sexual Organs Consequent upon Parturition," which he had prepared for the last meeting of the American Medical Association. While there might be some diversity of opinion in regard to a few minor points touched upon in it, the most distinguished gynecologist living might have been proud to have written it. It was not perhaps generally known that Prof. Gross had many years ago translated a manual of obstetrics, and a copy of this now rare work, which had been given to him by his classmate at college, the late Governor Andrews, of Massachusetts, he begged leave to present to the Academy.

The last occasion on which Dr. Gross had been present at the Academy was on the evening when the present hall was first opened. Dr. Acland, Regius Professor of Medicine at Oxford, in his speech alluded in the warmest terms to Dr. Gross, speaking of him as the senior graduate of Oxford. No one then present can forget his appearance when called upon by the Chair. It was evident that he had not anticipated such a call, but his speech was the most touching, from its effective simplicity, of any made that evening. It came straight from the heart, dropping with it, as his speeches always did, some suggestive thoughts. Dr. Barker closed with an eloquent tribute to the memories of both the illustrious surgeons.

THE DEATH OF DR. WM. H. HUBBARD.

DR. F. A. BURRALL then introduced, with a few appropriate remarks, the following resolutions, which were unanimously adopted:

Resolved, That the sympathy of the Fellows of the Academy be expressed to our esteemed and well-tried fellow-associate, Dr. Samuel T. Hubbard, in view of the great sorrow which he has experienced in the loss of his son, Dr. William Hustace Hubbard, who has been taken away at the very threshold of a promising career.

Resolved, That in this loss we recognize the fact that another name has been added to the list of those who have met an honorable death while in the discharge of professional duty.

Resolved, That a copy of these resolutions be sent to the family of the deceased.

The scientific work of the evening being now in order, DR. R. W. AMIDON read a paper entitled

A PLEA FOR MORE HEROIC SURGICAL INTERFERENCE IN AFFECTIONS OF THE BRAIN,

which will appear in full in our next issue.

DR. JOHN P. GARRISH said that he believed that the surgeons of the present day, as well as those of the past, had omitted the use of the trephine to too great an extent. He then related the case of a tailor who suffered from epilepsy in consequence of a blow upon the head. When he consulted Dr. Garrish he had already been subject to the epileptic seizures (which often occurred two or three times a day) for five years, and had consulted a number of physicians and taken a great variety of remedies without obtaining any permanent relief. On making an examination of his head, Dr. Garrish found a slight depression near the centre of the cranium, and, in consequence, decided to trephine him. A large portion of bone, which was found to be depressed one-sixteenth of an inch, was removed, and from that time the epilepsy entirely disappeared. The result obtained in this case induced him always to make very careful inquiries in every case of epilepsy that he met with as to whether it was of traumatic origin or not, and if on examination he found any depression of the skull, he did not hesitate to operate. In this manner he had completely cured five cases of epilepsy. Whenever there was any necessity for it, he cut through the dura mater without fear of any evil consequences, and if there was any extravasation of blood beneath it, this procedure was unquestionably called for. In this connection he related a case which he had met with after the battle of Antietam, while serving as an army surgeon during the late war. He accidentally discovered a soldier who had been lying in a barn in a state of unconsciousness, without food or drink, for three days. Finding that life was not extinct, he made an examination and discovered a depressed fracture of the skull. He at once trephined

the man, and finding that there was a considerable accumulation of blood under the dura mater, he cut through it and liberated the blood, with the effect of at once causing the patient to regain consciousness and open his eyes. He afterwards made a complete recovery. In certain conditions he considered trephining not only a justifiable but a necessary operation, and he believed it to be accompanied by very little danger. There were some cases of apoplexy, which were ordinarily left to die, which he thought might come to a favorable issue if trephining were promptly resorted to, and the lancet also used in connection with it. The brain was literally swimming in its own blood, and if a portion of this blood at least were removed in time, the patient would recover.

DR. M. JOSIAH ROBERTS remarked that as the paper suggested a more frequent resort to opening the skull, it was advisable that the *technique* of the operation should be improved in every possible way. With this end in view, therefore, he had devised an electrical apparatus which he thought would both facilitate its performance and diminish its dangers. It was somewhat analogous to the dental engine, but with it a considerably larger drill could be employed than with the latter. By means of this instrument, a section of a circle three-quarters of an inch could be removed, while the section could be made of any smaller size that was required. The division of the bone occupied but five seconds, and the instrument possessed the great advantage that it could be manipulated with the same delicacy of touch that a probe could.

DR. H. D. NOYES said that it had twice been his lot to deal with cases such as had been described in the paper. One had been alluded to in the latter, and the other had occurred many years ago, when antiseptic surgery was still unknown. It was that of a young man, who met with a fracture of the skull, from which resulted a fissure in the frontal bone situated in the orbit of the right eye. There was a purulent discharge, and the patient suffered from convulsions. At times he also had paralysis. The frontal bone was trephined just above the eyebrow, and three drachms of pus were evacuated. Increased frequency of the pulse and a rise of temperature followed the operation, but he ultimately recovered. Dr. Noyes said that he had been induced to operate by the fact that Dr. Detmold had before that boldly plunged a bistoury into the brain-tissue. His own operation was in 1867, and he thought, therefore, that it had been in the minds of surgeons to resort to operative procedure whenever the diagnosis and knowledge of the condition warranted it and the indications were sufficiently clear. In the second case, which had been referred to in the paper, there was no suspicion that a piece of iron five inches long was buried in the brain. It was probable, however, that if it had been allowed to remain, the patient's life would have been spared for a considerable time. In regard to the use of quinine and alcohol in such cases, he said he should like to inquire whether or not there was a general concurrence of sentiment as to their inadmissibility. It was probable that he would never again have to treat another of these cases, but he desired to know, if this should occur, whether he would be obliged to withhold these remedies if rise of temperature or other symptoms in which they were, under ordinary circumstances, indicated, should make their appearance.

DR. PUTZEL said that when he was still a student, his attention had been directed to this subject by some of the autopsies which he was accustomed to see at Bellevue Hospital. When he had seen blood accumulated under the dura mater as the result of concussion, etc., it had occurred to him sometimes, that if the skull had been trephined, it would, perhaps, have given the patient an additional chance of life. But this, he thought, was not the class of cases referred to in the paper. The statistics which the writer had given were open to the objection (which could be urged against all recent statistics), that only the favorable cases, as a rule, had been published. A considerable number had undoubtedly been left unreported, and this vitiated their accuracy. It was very natural that surgeons should hesitate to publish cases in which not only had there been an unfavorable result, but the autopsy showed that a grave mistake had been made in diagnosis; as was probably the case in a considerable number of other instances. He thought that Dr. Noyes had struck the keynote of the whole matter, when he said that the propriety of operating in any case depended to a great extent on the diagnosis and the knowledge of cerebral localization. In cases in which there was supposed to be a surface lesion, there might be an abscess several inches distant from the surface, and the cortex be found healthy. It was only in regard to the motor centres that we had at present any positive knowledge, and he thought that our means of diagnosis would have to be further advanced before we could be prepared, as a rule, to operate on the brain. With regard to the use of quinine and alcohol, he did not think that the question was at present definitely determined. In these cases it was necessary to take into consideration the condition of the heart, as well as the brain, and if there was any danger of the failure of this organ, he believed that we were called upon to give the patient alcohol. He thought the author of the paper was hardly justified in recommending chloral as freely as he had done. It might take an hour or two to secure any appreciable effect from the remedy; and if ten or fifteen grains were given every fifteen minutes, unpleasant results might ensue from the accumulation of the chloral in the system.

DR. AMIDON remarked that the contra-indication of quinine and alcohol was not definitely established, but in the case of phthisis, to which he had referred in the paper, in which he gave two and a half grammes (40 or 50 grains) of quinine a day, an attack of well-marked acute basilar meningitis seemed to be set up by it. The symptoms yielded to large doses of iodide of potassium, and when, some time afterward, the patient died of the phthisis, no trace of it, except a slight opacity, was left. There was no evidence whatever of tubercular meningitis in this case. He did not differ from Dr. Noyes in the opinion that if the foreign body had been allowed to remain, it would eventually have produced a fatal result. He thought Dr. Putzel had somewhat misunderstood him in what he said in regard to cerebral localization, which was, that neurologists were perfectly sure that there were certain definite regions of the brain, the irritation or destruction of which gave rise to unmistak-

able symptoms, such as localized paralysis and localized epilepsy.

PUBLIC PARKS.

DR. F. A. CASTLE then introduced a resolution, which was unanimously adopted, urging upon the Governor of the State, the signing of a bill recently passed by the Legislature, which provides for the purchase of several suitable tracts of land for use as parks in the upper part of the city. In pointing out the desirability of securing these lands, Dr. Castle referred to the very meagre manner in which New York was at present supplied with parks, as compared with either London or Paris.

On motion of DR. CASTLE, the By-laws were suspended and the Academy adjourned until the first Thursday in October, next.

ONTARIO MEDICAL ASSOCIATION.

Fourth Annual Meeting, held at Hamilton, June 4 and 5, 1884.

(Specially reported for THE MEDICAL NEWS.)

THE Association met at 10 A.M., in the City Council Chamber, THE PRESIDENT, DR. DANIEL CLARK, of Toronto, in the Chair.

After the registration of members and routine business, the reading of papers was proceeded with, the first paper being by DR. WORKMAN, of Toronto, on

APHASIA.

The greater portion of the paper was devoted to that form of the disease termed by Kussmaul *verbal deafness;* but motor and amnesic aphasia were also referred to. He traced in a few words the little that was known of this affection from the earliest records of Hippocrates down to the fuller and more scientific disquisitions of the present on the subject. He thought that it had almost undoubtedly been shown that Broca's, or the third frontal, convolution was closely and intimately concerned in the faculty of articulate speech, and hence was evidence in favor of the theory of cerebral localization.

DR. J. D. MACDONALD, of Hamilton, said that, as a general practitioner, he felt diffident in undertaking to discuss this paper, which required a specialist for its proper elucidation. Nevertheless, as a general practitioner, he occasionally met with cases of aphasia associated with paralysis of the right side to a greater or less degree of severity. He then detailed the case of a clergyman, an energetic, intellectual man, with an abundant flow of words. He became suddenly aphasic, and paralyzed on the right side. His vocabulary was limited to the words yes and no; in other respects he was quite well. In time he recovered sufficiently to resume his occupation, but slight defect in certain words always remained.

DR. MULLIN, of Hamilton, related the case of a business man, in good health, who had been detected making a very curious series of entries in his books. Some words were wrong and others partly finished. He slowly improved, and in time the deficiency passed completely away.

THE PRESIDENT dissented from the doctrine of cerebral localization. He regarded the cerebrum as a whole, as the receptacle of psychic impressions. He thought the localization theory as yet unproved.

DR. GEIKIE, of Toronto, related a case of amnesic aphasia. He heartily agreed with Dr. Workman in his remark that the writings of past generations were not sufficiently read and appreciated by the present generation of medical men.

DR. BRAY, of Chatham, related a case of aphasia in a puerperal woman, who had had an abundance of albumen in her urine. There was paralysis of the right side. Complete recovery followed.

AFTERNOON SESSION.

THE PRESIDENT, DR. DANIEL CLARKE, of Toronto, delivered the

ANNUAL ADDRESS.

After expressing his thanks to the Association for the honor conferred upon him, and his hope that he might be able to discharge the duties of the office in the same admirable manner as the Nestors of the profession who had preceded him in the presidential chair, he proceeded to a mild criticism of matters appertaining to the profession. The first matter referred to was the increase in educational facilities during the last few years, which he considered a matter of congratulation, and that there was no excuse to be offered for students with their present facilities and privileges, the results of which are to be seen in the improved culture of the younger members of the profession. In connection with this improved culture, he thought that great credit was due to the colleges and central licensing body for the institution of a higher curriculum. The President then referred to various advertisements in the different papers, both religious and secular, many of which advertisements, by their covert allusions, did great mischief to the morals of the community, especially to those of weak mind; allusion was also made at some lengh to many of the advertisers who were really worse than criminals. In conclusion, reference was made to the attitude which should be adopted by the profession in regard to prognosis especially, but also to the public generally, always maintaining a cheerful countenance, as so much attention was paid by the public to the countenance of physicians.

DR. POWELL, of Edgar, then read a paper on the

LATER ANTISEPTICS IN PRIVATE PRACTICE,

illustrated by specimens of various dressings, as wood wool, peat, iodoform gauze, corrosive sublimate gauze, decalcified bone tubes, etc., now used in the New York hospitals. He said that the security and success attending the use of these measures more than compensated for the additional trouble, while the expense was not now so great as to make it a drawback. He related a series of five cases of incised wounds of the knee-joint occurring in his practice which had been successfully treated under antiseptic dressings. He advocated cleanliness, elastic pressure, rest, and antiseptics.

DR. TYE, of Chatham, followed with a paper on

THE MANAGEMENT OF THE THIRD STAGE OF LABOR.

He discredited the Credé method of expelling the placenta, and advocated gentle pressure and manipulation over the fundus of the uterus.

DR. MACDONALD, of Hamilton, left the placenta

alone for some time, even for an hour, till it was completely detached.

DR. BRAY, of Chatham, gave an instance of his first and only trial of the Credé method. The result was unfortunate and troublesome, there being relaxation and profuse hemorrhage afterwards.

DR. BRYCE, of Toronto, wished to know the rationale of the brandy and ergot mixture given in cases of flooding in the third stage. He thought their physiological actions were antagonistic.

DR. RICHARDSON, of Toronto, said that he had been brought up in that school which deprecated meddlesome midwifery. He never worried and irritated the uterus by premature attempts to extract the placenta. He waited, and when it was lying in the vagina or partly in the vagina and partly in the os, by slight traction on the cord or by inserting one finger over the edge of the placenta, the air rushed in and the placenta was expelled without trouble. In a long course of practice he had never had those troublesome cases of irregular uterine contractions called hour-glass contractions. He did not consider brandy and ergot antagonistic; the ergot was given for its specific action on uterine fibre, and the brandy was always indicated in collapse and syncope from excessive loss of blood, and in these cases he gave it with unstinted hand.

DR. MULLIN, of Hamilton, said that when the placenta was lying in or near the os it was safe to leave it to the natural action of the uterus for expulsion; but when it was situated at a higher plane there was danger of hemorrhage, and physical interference perhaps was demanded. In any case the woman was not to be left till firm and continued contraction was induced. He always remained with his cases till he secured this, and then left with a light heart in the full assurance that they were safe.

DR. GUNN, of Brucefield, thought it best to wait about fifteen minutes before endeavoring to expel the placenta. The cord was frequently cut too soon, the child losing an appreciable quantity of blood by having the supply cut off too hurriedly. To prevent entanglement and breaking of the membranes, the placenta should be extracted just at the conclusion of a pain, as slight relaxation is setting in.

DR. HARRISON, of Selkirk, wished to know how one was to tell if all the membranes were away. His plan was to give a large dose of opium, or morphia, and thus place the patient in the constant security of rest and ease.

DR. WORKMAN found that the men of this generation were gradually returning to the principles of treatment advocated by him more than forty years ago.

DR. GRIFFIN, of Brantford, presented a specimen of

CANCER OF THE CÆCUM,

with the history of the case. T. W., æt. 66, female, of excellent health up to six years ago, when occasional attacks of diarrhœa occurred, followed by constipation and obstructive symptoms. Large quantities of gelatinous mucus, at times of great length, were frequently seen in the dejections. In 1882 a tumor the size of a walnut was discovered in the left mamma. The family history pointed to malignancy. A slight hemorrhage led to a rectal examination, when a small tumor was discovered in the upper part of the rectum. The distress gradually increased. Nodular growths appeared around the cervical, subclavian, and axillary glands, and two months before death complete obstruction ensued, no fecal matter whatever passing or coming away with enemata. The superficial tumors in the last few weeks of life diminished greatly in size. One week before death a liquid fecal discharge passed from the rectum. At the autopsy the abdominal organs alone could be examined. At the cæcum a hard tumor was found obstructing the lumen of the gut, so that a No. 4 catheter barely passed. There was no other sign of disease present in the abdominal cavity.

DR. A. H. WRIGHT, of Toronto, read a paper on the

PREVENTION OF PUERPERAL FEVER.

He took as his text that portion of the recent discussion in the New York Academy which referred to prevention. He objected to two principles in Prof. Thomas's rules: 1. The view that labor should be considered in the light of a capital operation. He thought preparations made with such a view had a very depressing effect. He gave instances in his own practice, showing serious results of emotional influences, and believed that such results were not always temporary, but sometimes led to serious lesions. 2. The advisability of prophylactic vaginal injections and the introduction of suppositories. He considered them both distasteful to the patients, and unscientific on surgical grounds.

In giving his own views he referred to the importance of surgical cleanliness, the dangers of stretching a slowly dilating cervix with the fingers, the necessity for depending upon expulsion for complete delivery of child, the desirability of keeping up constant but remittent pressure and kneading of the uterus, not so severe, however, as practised in Credè's method, and, generally speaking, defended the teaching of conservative obstetricians.

DR. POWELL, of Edgar, thought that the paper showed that the author had put his heart into the work. In tedious labors with rigid os, the temptation was strong to undertake digital dilatation. He had practised dilatation on various occasions, but in two or three cases developing cellulitis after such proceedings, he had discontinued the practice.

DR. BRAY, of Chatham, thought that the dangers of puerperal infection were reduced to a minimum by efficient contraction of the uterus. When he had secured that, he left the case satisfied.

DR. BURNHAM, of Toronto, read a paper on

CARBOLIC ACID IN PURULENT AFFECTIONS OF THE EYES,

in which he advocated the use of a solution of one in forty at first, to be increased to one in twenty. The eye was to be irrigated with this solution hourly, day and night. At the same time, cloths wet with ice-water were to be kept constantly applied, being changed frequently. With this mode of treatment he did not find it necessary to shield the bandage more than by keeping the patient lying with the diseased eye downwards. It was necessary to make use of the purest acids, as others were irritating. This method of treatment was drawn from his experience with a very large number of cases. Other antiseptic and astringent applications had failed to give equal results.

DR. HOWE, of New York, said that he saw no special advantage in the carbolic acid treatment over that with

nitrate of silver and other astringents with ice-water. We had other antiseptics equally effective. He gave statistics of purulent ophthalmia in children in a large hospital, where, of 3000 children, the percentage of conjunctivitis was from nine to fourteen per cent. This meant a large proportion of blind children. After the introduction of perfect cleanliness and antiseptics, this percentage fell to nothing.

DR. THORBURN, of Toronto, reported a case of

DISLOCATION OF THE FOURTH AND FIFTH CERVICAL VERTEBRÆ.

Death occurred in twenty-four days. He gave a *resumé* of all such cases that had been reported.

DR. BROUSE, of Brockville, read a paper describing

A CASE OF OVARIOTOMY.

On opening the peritoneal cavity, six quarts of pale, straw-colored, syrupy liquid were discharged. There were no adhesions. The case did well.

He also read a paper describing two cases of

STRANGULATED HERNIA.

They were both operated on, the sac being opened in each case, and the bowel found dark and gangrenous. One case recovered; the other, an old, feeble patient in whom obstruction had existed seven days, died.

Drs. Groves, Campbell, and others, took part in the discussion of these cases.

JUNE 5TH—SECOND DAY.

MORNING SESSION.

DR. GRAHAM, of Toronto, read a paper on

IDIOPATHIC ANÆMIA.

He had met with seven cases in all of this obscure disease. The cases were carefully and minutely detailed. Most of them were males, chiefly farmers, well on in years. Recovery was undoubted in one case, and in another there was considerable improvement. In the treatment, arsenic was mainly relied on; it appeared to benefit mostly in the latter stages.

The etiology of the disease appeared most obscure. He mentioned as a possible hypothesis that it might be a central nervous lesion, causing a change in the corpuscular element of the blood in a manner somewhat analogous to that in progressive muscular atrophy.

DR. ARNOTT, of London, said that he had had many cases of profound anæmia under his charge. He had been moderately successful in the treatment of these by iron, arsenic, phosphorus, etc. One case resisted all means; he was in despair, when his attention was attracted by a notice of the peculiar tonic effects of eucalyptus. He tried the fluid extract, and, to his surprise, improvement began and progressed rapidly. Since then he has used it with constant benefit in nearly all cases of anæmia.

DR. SHEARD, of Toronto, thought that an error was made in referring all obscure diseases to the nervous system. He had made the post-mortem examination of one of the cases with Dr. Graham, and failed to discover any sufficient cause for such an hypothesis. In this case he had made a most careful autopsy, and found no lesion of the nervous system. He thought the fluids of the blood might possibly be in such an abnormal state as to produce the changes found in the blood corpuscles.

DR. CAMERON suggested that, like scorbutus, this disease might be due to an insufficient supply of vegetable food.

DR. TURVER, of Parkdale, read a paper on

STUDIES IN UTERINE DISPLACEMENTS,

and showed a soft rubber anteversion pessary modelled after Gehrung's, which he had made of soft rubber, adding a diaphragm over the upper arms for the purpose of supporting the arms.

DR. GROVES, of Fergus, read a paper on

SURGICAL OPERATIONS IN CHEST EFFUSIONS,

in which he advocated a double opening and free drainage when pus was present. He detailed a number of cases which had done well under this treatment.

DR. POWELL, of Edgar, had operated in many cases, and showed a plan adopted by him for retaining the drainage-tube, which he made of a Jacques's soft-rubber catheter. This he strengthened with some firm material to prevent compression, and passed it through a hole in a Martin rubber bandage, worn around the chest.

DR. RICHARDSON, of Toronto, had adopted the siphon method of draining the pleural cavity many years ago, with results eminently satisfactory.

DR. TEMPLE, of Toronto, had given up making the second opening. He thought that after the formation of pus it was a matter of indifference if air entered the pleural cavity.

DR. HUTCHINSON, of Brussels, exhibited a case which he supposed to be one of *Hodgkin's Disease*.

CEREBRO-SPINAL FEVER.

DR. WORTHINGTON, of Clinton, read a paper detailing the history of cerebro-spinal meningitis as it had appeared in an epidemic in his section of the country several years ago.

DR. HARRISON, of Selkirk, adverted to a form of disease which he had described a year ago—beginning suddenly, and bearing a close resemblance to typhoid, but puzzling all who came in contact with it by its recrudescences and lengthened course. He had recently met with another case, which began suddenly and closely resembled hemorrhagic variola. It proved to be a case of cerebro-spinal meningitis. It also took on the protracted and curious form. He was inclined to believe that these anomalous fevers were all cerebro-spinal.

DR. WHITE, of Toronto, said that in an epidemic of cerebro-spinal fever he had met with some years ago, the cases all followed the course of the river, avoiding the high grounds on either side.

DR. OSBORNE exhibited a case of *Epithelioma of the Face*.

DR. REID exhibited a case of *Knee-joint Disease* which began two years ago after an injury.

AFTERNOON SESSION.

DR. RIORDAN, of Toronto, described a unique case of *Double Uterus and Vagina*. He purposed removing the vaginal septum.

DR. BROWN, of Galt, presented some

GLIMPSES OF TRANSATLANTIC SURGERY,

in which he detailed his impressions of many of the eminent surgeons of Edinburgh and London. He

strongly advocated frequent stated visits to these and similar centres of medical thought.

Dr. A. M. Rosebrugh of Toronto, read a paper on

BOROGLYCERIDE IN THE TREATMENT OF SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR,

in which the point was emphasized that suppurative inflammation of the drum-cavity is a disease that preëminently calls for antiseptic treatment. The indication is to keep the tympanic mucous membrane constantly bathed in a solution which, while it is antiseptic, is not irritating, and while it is gently astringent it does not form coagulations with the secretions. Solutions of boroglyceride in glycerine seem to meet these indications better than any known antiseptic. Finely pulverized boracic acid has been used with much success by Bezold and others, but, other things being equal, a fluid, at least on theoretical grounds, would seem to be better adapted to the *mucosa* than a powder, however finely it may be triturated. Boracic acid, moreover, does not supplant, but simply assists other methods of treatment, whereas the boroglyceride, at least in the hands of the author, not only destroys all fetor and quickly arrests the discharge, but it also destroys polypoid granulations without resort to caustics. Boroglyceride is prepared by heating together in an evaporating-pan, two ounces of boracic acid and three ounces of glycerine, the acid being added gradually, and the heat continued until the mass is reduced to exactly three and one-third ounces, or two-thirds the original weight. On cooling it is an amber-colored, vitreous mass, which is very friable and easily broken when sufficiently evaporated. It is readily soluble in glycerine, but much less so in water. It is used dissolved in glycerine—the treatment commenced with a fifty per cent. solution, and the strength gradually reduced as the discharge diminishes. The treatment is largely entrusted to the patients, they being seen but twice or three times a week, when the meatus and tympanic cavity are thoroughly freed from all secretions by means of syringing with a warm solution of boracic acid, and Valsalva inflations, or the use of an Eustachian catheter. The meatus is half filled with the boroglyceride (warmed), and the air forced through it by Valsalva inflation, or the catheter. The tragus is also pushed backwards and inwards, so as to force the medicament into the middle ear. The boroglyceride is kept in position by means of a plug of absorbent cotton, or borated cotton soaked in vaseline. The patient repeats the process as well as he can, night and morning, at home. By this treatment it is claimed that the patients can be discharged cured in less than half the time required by the usual methods.

Dr. W. H. B. Aikins, of Toronto, read a paper on

SPERMATORRHŒA.

The differences between pollution and spermatorrhœa were pointed out, and that patients were often thought to have seminal discharge when it was only prostatic secretion. The microscope affords the only reliable means for a diagnosis. Seminal emission may be considered physiological when the discharge is followed by a feeling of well-being; if followed by malaise, it is pathological.

In spermatorrhœa, endoscopic examination shows hyperæmia of veru montanum, a catarrhal state of the mucous membrane, the orifices of the ejaculatory ducts are more prominent, and their edges thicker than normal.

Treatment consists in removing the source of irritation, tonics, medicines to reduce reflex irritability and regulate circulation. If great hyperæsthesia exist, unmedicated gelatine bougies, or bougies of cocoa-butter containing extracts of opium and belladonna should be used. The use of metal sounds and the cooling sound, or catheter of Prof. Winternitz, is highly beneficial. When the hyperæsthesia is lessened, recourse should be had to deep injections of five per cent. solution of nitrate of silver.

Dr. Campbell, of Seaforth, reported a case of

EXOPHTHALMIC GOITRE

in a woman, æt. 45. The symptoms began shortly after a severe fright. When she came under observation, the symptoms were well marked—she also had hemorrhagia. Iron, quinine, digitalis, and ergot, were given for some time—the last on account chiefly of the profuse menstrual flow. In January, 1883, severe gastric disturbance set in, and nothing was retained but small quantities of milk and lime water. By March she was greatly reduced, temperature 101°, probably due to gastric catarrh, though possibly to the goitre. Murmurs over all valves of the heart, and great throbbing of large vessels. Food and medicines were given by the rectum. Galvanism along the course of the pneumogastric was resorted to twice daily for five minutes. After a few days she was able to take fluid food—solids in two weeks. In six weeks she partook of her usual diet and attended to household duties. She is now quite well; eyes normal, no murmurs or any symptoms of her illness. Ergot and digitalis seemed to be the most effective medicines in this case. The author was not prepared to say how much benefit should be attributed to the galvanism. Hammond reports cures from its use alone.

Dr. Harrison, of Selkirk, read a paper on

VACCINATION,

in which he dealt with the coincidence theory of the subsidence of smallpox after the generalization of vaccination. He said it was just as reasonable to attribute the soporific effects of morphia to coincidence.

Dr. Boyce, of Toronto, said that bovine virus was not always perfectly satisfactory; that at times the virus produced most unpleasant effects or was inert. If the virus lay in the pure lymph, it was necessary to get this pure, and not mixed with pus, blood, and epithelium. He thought the importance of this question justified him in exhorting all members of the profession to be more than particularly careful and circumspect in obtaining and using vaccine.

The Nominating Committee presented their report, which was adopted. They recommended that the *place of meeting*, next year, should be in London.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. Addison Worthington, of Clinton.

Vice-Presidents.—Drs. Tye, of Chatham; Thorburn, of Toronto; Brouse, of Brockville; Powell, of Edgar.

Permanent Secretary.—Dr. White, of Toronto.

Treasurer.—Dr. Graham, of Toronto.

Corresponding Secretaries.—Drs. Irwin, of Kingston; Harris, of Brantford; and Waters, of Cobourg.

A number of other papers were then read by title. The reports of the various committees were handed in and accepted as read. The meeting then adjourned after giving the usual vote of thanks.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, May 27, 1884.

THE PRESIDENT, R. F. WEIR, M.D., IN THE CHAIR.

DR. A. C. POST read a paper entitled

CONGENITAL DEFORMITY OF HAND; COMBINED ECTRODACTYLISM, AND SYNDACTYLISM.

(See page 691.)

At the conclusion of the paper, Dr. Post remarked that the one most important point was, in difficult cases, to operate separately upon each individual space. If all are operated upon at once it sometimes gives rise to serious inflammation, and there is always increased difficulty in applying the dressings.

SARCOMA OF THE LOWER JAW.

DR. POST presented the specimen, which was interesting especially on account of one point connected with the operation. The tumor was removed from a girl twenty years of age. The existence of the tumor had been recognized eight months. He divided the jaw bone through the middle, and removed all the swollen part of the jaw, the outer incision extending to the angle, when he found marks of the disease extending further. He then removed a second, and finally a third, segment of bone. After removing the first segment of bone there was rather copious hemorrhage, which came from the inferior maxillary artery, which he plugged with wax. After making the second section of the bone the hemorrhage was profuse, and could not be controlled by means of wax, and he therefore drove a wooden plug into the bone. Afterwards he cut above the entrance of the inferior maxillary artery into the bone, and no hemorrhage followed. The laceration of the artery by driving the wooden plug into it had completely arrested the hemorrhage, so that afterwards, when the ramus of the bone was divided above the entrance of the artery, there was no trace of hemorrhage.

MYOFIBROMATA OF THE UTERUS; LAPAROMYOMOTOMY.

DR. L. A. STIMSON presented the uterus with myofibromata attached, which he removed, on the 24th of May, from a colored woman thirty years of age. The patient was sent to him from New Jersey, with a history of tumor, which was first noticed eighteen months ago in the lower portion of the left side of the abdomen, and which caused so much pain and distress that she was unable to earn her living. She was the mother of one child, born ten years ago. On examination he found a firm, irregular tumor extending a little from the right of the median line above the pubes upwards to the left, and occupying the left iliac fossa to the height of the umbilicus, and it could be felt through the vagina in front of the uterus. The patient was kept under observation for a few days, when it was found that the tumor had changed its position somewhat, and by exploration of the uterus it was found to be independent of it, or at least movable upon it. A second tumor, thought to be the uterus, was felt behind and to the right of the main tumor. The diagnosis was that of a pedunculated fibroid of the uterus with other fibroid growths within the uterus. An operation was undertaken for their removal by making an incision in the linea alba from the umbilicus downwards, under bichloride irrigation, and after the bleeding had been completely arrested the peritoneum was divided to an extent sufficient to admit four fingers, when the diagnosis was confirmed by digital examination. The tumor was brought out through the incision, consisting of a mass somewhat heart-shape in form, measuring about five inches in its greatest diameter, irregular in outline with many nodules, and connected with the anterior surface of the uterus by a narrow pedicle. On drawing out the left ovary it was found that the broad ligament was increased in width and length, and that the ovary was at some distance from the uterus. The ligament was transfixed below the pampiniform plexus with an ivory pin carrying a double silk ligature, and the ovary with the plexus was cut off with the tube. Then bringing the right ovary into sight, it was found so closely attached to the uterus that a ligature could not be safely attached without causing an unfavorable amount of bleeding, and as the cervix was long and narrow, he decided to remove the entire organ by amputation through the cervix. The uterus was drawn up, the cervix was transfixed with an ivory pin carrying a double silk ligature, by means of which a round rubber cord, about three millimetres in diameter, was carried and tied upon either side, and the organ with the remaining ovary was cut off above. The pedicle was so long that it could be easily brought into the abdominal wound, and was secured in the lower angle with two pins. There was no hemorrhage except very slight from the puncture of the cervix by the ivory pin, and when the operation had been completed, and the sponge was introduced into Douglas's cul-de-sac, it brought away only one small clot about an inch in length and about the size of a lead pencil. The peritoneum was united by a continuous catgut suture, as was also the aponeurotic layer. Six silver sutures were then passed about two inches from the edges of the abdominal wound and made fast with buttons. The stem of the pedicle was transfixed with two steel needles resting in the skin, and the cutaneous incision closed with a continuous catgut suture. A decalcified bone drainage-tube was inserted under the skin from the upper angle of the wound to the pedicle, and the whole was covered with iodoform and gauze. On the next day, as there were some abdominal tenderness and slight elevation of temperature (101°), the dressing was removed, some dry bloody serum was found and the wound was dry. He covered the wound with a little gauze, kept wet with the bichloride solution, and applied the leaden coil, and under that treatment the pain had diminished, and the temperature had sunk to 100.25°, and now, on the fourth day after the operation, the patient was apparently out of danger. She had also received a small quantity of morphine, about thirty minims of Magendie's solution in the course of twenty-four hours. May 31st, patient doing well.

COMPOUND FRACTURE OF THE SKULL.

DR. STIMSON also presented a specimen which showed much more extensive fracture of the inner than of the

outer table of the skull. The patient was walking upon the street when a brick fell from a building and struck him upon the right temporal bone about one inch to the outer side of the median line, driving in a portion of the skull to the depth of nearly one inch at the deepest point. The patient remained conscious. On the 24th of May, when he saw him, three hours after the receipt of the injury, he found a ragged wound of the soft parts, exposing a denuded area of bone, and from the broken edge of the bone there came out a small quantity of brain matter. Dr. Stimson gnawed away the adjacent portion of bone, and was able, after enlarging the opening somewhat, to withdraw the piece of skull presented, of which the outer table was somewhat irregular and perhaps three-fourths of an inch in diameter, while the inner table was one inch and a half in diameter. The patient was doing well. The escape of brain matter ceased as soon as pressure was removed.

VESICAL CALCULUS REMOVED BY LITHOLAPAXY.

DR. STIMSON also presented a specimen of hard phosphatic stone, which, on the 14th of May, he removed from the bladder of a man fifty years of age. The time consumed was about forty minutes. Before the operation the patient was passing water every fifteen minutes or half an hour, and there was considerable cystitis with ammoniacal urine. On the day following the operation he was able to hold his urine for five hours. The special point of interest in connection with the operation was that he used only small instruments, nothing larger than No. 28 French, although the urethra was roomy. The stone weighed three hundred grains.

THE KENTUCKY STATE MEDICAL SOCIETY.

Twenty-ninth Annual Meeting, held at Bowling Green, June 3, 4, and 5, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 3D—FIRST DAY.

THE twenty-ninth annual meeting of the Kentucky State Medical Society was called to order at Bowling Green, by THE PRESIDENT, DR. J. N. MCCORMACK, at 2 o'clock P. M.

DR. S. J. TOWNSEND, of Bowling Green, Chairman of the Committee of Arrangements, made an address of welcome, which was seconded, on behalf of the residents of the city, by the Hon. C. W. McElroy, and responded to on behalf of the Society by Dr. Dudley S. Reynolds, of Louisville.

DR. J. P. PEMBROKE, to whom had been assigned the subject of

MATERIA MEDICA,

reported that he had given a fair test to the hypnotic *paraldehyde* suggested as a substitute for chloral and opium, and his investigations had led him to regard it as a very mild hypnotic, adapted only for those cases of insomnia due to excitation of the nervous system. *Kairine*, as an antiperiodic and febrifuge, unless used in dangerous doses, he found not equal to salicylic acid or quinine. He remarked that he had unexpectedly produced almost fatal paralysis of the heart by its use in one case with ten grains. *Hyoscyamine*, in one case of insanity of the form of acute mania, seemed rather to increase than allay the excitement.

DR. J. M. MATTHEWS, of Louisville, said that he had used chloral for years, and found it a very uncertain and sometimes dangerous drug.

DR. J. W. HOLLAND, of Louisville, had hoped to hear included the word opium, in connection with chloral, in reference to their mutual action upon the form of insanity known as melancholia. Sydenham, however, called attention, more than a century ago, to the cordial qualities of opium. If there be already a melancholia, it proves more profound when chloral is employed than when opium is used, and the tendency to suicide is increased. Hyoscyamine is responsible for the same effect.

DR. STONE, of the Western Lunatic Asylum, at Hopkinsville, said that hyoscyamine had been used in that institution, not only very extensively, but almost altogether, hypodermatically and in large doses; frequently attaining by this method, as high as one-twelfth or one-tenth of a grain. In smaller doses it has been kept up for ten or twelve weeks, but without any apparent advantage over other drugs used to accomplish the same purpose. It will procure sleep, and that very promptly, in acute mania, and sometimes better than chloral. He agreed with Dr. Holland as to the superiority of opium over chloral in melancholia.

DR. W. M. FUQUA, of Hopkinsville, had used chloral from its very earliest introduction. He thought there could be no question that it produces, when long continued, an anæmia of the brain; that it exercises a powerful effect on the cardiac centres, and that its action is cumulative. It is anæsthetic as well as hypnotic.

DR. R. M. FERGUSON, of Louisville, read a paper on the *Nature of Glaucoma*.

DR. A. M. VANCE, of Louisville, called attention to

A NEW METHOD FOR PRODUCING LOCAL ANÆSTHESIA

for the minor operations in surgery. It consisted in a modified application of the spray of ether. Dr. Vance stated that anæsthesia occurs long before the parts are frozen, and he begins his operations a few seconds after the spray begins to play upon the part. In this way an eye had been enucleated without general anæsthesia; a tracheotomy had likewise been successfully performed, and he had cut the whole plantar fascia in a child without a flinch, beyond what was first made when the cold ether struck the surface. He said it was his uniform custom to resort to it alone in all tenotomies.

DR. PINCKNEY THOMPSON said that he had only practised it in one instance of hemorrhoids, and in that it was certainly preferable to general anæsthesia.

DR. J. M. MATTHEWS said that he had tried this plan in several cases, but his experience had not been so favorable as Dr. Vance's. In the limited number upon whom he had tried it the pain following the operation had been excruciating.

DR. T. H. STUCKY, of Louisville, then read a paper on *Catarrhal Headache*.

WEDNESDAY, JUNE 4TH—SECOND DAY.

MORNING SESSION.

DR. L. S. MCMURTRY made the report on

THE PROGRESS OF SURGERY,

the first portion of which was devoted to a consideration of the subject of anæsthetics. Recent investigations as

to the comparative merits of sulphuric ether, chloroform, bromide of ethyl, and anæsthetic mixtures of these agents, were reviewed in detail. The experimental investigations of Dr. B. A. Watson, of Jersey City, were carefully considered. The deductions were that sulphuric ether is decidedly the safest anæsthetic which has yet been employed in surgical practice, the mortality being relatively small when compared with that of chloroform, bromide of ethyl, and the mixtures employed. These results of experimental study are confirmed by clinical experience. Dr. McMurtry doubts if any agent will ever be found which can carry patients so near the border-lines of life in safety. He doubts if anything is accomplished in avoiding danger by the indiscriminate exhibition of alcohol before giving an anæsthetic. He then discussed the method introduced by Mollière, of administering the vapor of ether per rectum. The recent publications of Dr. William T. Bull, James B. Hunter, and Robert F. Weir upon this mode of anæsthesia, and the brief experience already recorded, he claimed, demonstrate the danger of the method as exemplified by intestinal hemorrhage and diarrhœa; but the advantages of a method which suppresses the period of excitement, permits accurate regulation of dosage, avoids bronchial irritation, and aids materially in operations about the face are apparent; and the method deserves to be tested thoroughly. In concluding this portion of the report the speaker commended the ether inhaler of Dr. Allis, of Philadelphia.

The greater portion of Dr. McMurtry's paper was devoted to recent improvements in abdominal surgery. He discussed at length the treatment of wounds of the intestines, and declared the indications of treatment in contused, lacerated, punctured, and gunshot wounds of the intestines to be prevention of fecal effusion and peritonitis. To secure the first, the wound of the tube must be securely sutured, however small it be. To do this, and cleanse thoroughly the peritoneum, the abdomen should be opened by abdominal section. The speaker, in this connection, called attention to the very confident views expressed by the late Dr. Marion Sims in 1882, which he then quoted: "I have the deepest conviction that there is no more danger of a man's dying of a gunshot or other wound of the peritoneal cavity, properly treated, than there is of a woman's dying of an ovariotomy properly performed," and remarked that in the able paper of Dr. Parkes recently given to the profession on this subject, this statement of Dr. Sims was deemed prophetic. Dealing with another branch of abdominal surgery, Dr. McMurtry alluded to the difficulties and uncertainties which surround the diagnosis of abdominal tumors. These difficulties were so great that in a large number of cases the diagnosis can only be positive when the abdomen is opened. He detailed illustrative cases from his own experience. In one case, that of a young lady with a fluid accumulation in the abdomen, the patient had been in the hands of several skilful surgeons, with a different diagnosis by each. After aspiration and the removal of two gallons of fluid, complete recovery ensued, thus showing the tumor to be a cyst of the parovarium. After discussing at length the differential diagnosis of abdominal tumors, the speaker concluded with the statement that "while the results already achieved in the brilliant domain of abdominal surgery surpass the expectations of the most speculative enthusiast of half a century ago, there remains a vast and rich outlying province as yet untrod by the restless foot of genius."

DR. A. W. JOHNSTON called attention to the absence of any reference to the importance of drainage in the treatment of wounds of the abdominal cavity, which is one of the most important features of the after-treatment of these wounds. Lawson Tait speaks of drainage by the alimentary canal. He says he has made it a practice to purge these patients, and that he secures excellent results from it. We all know that when a purgative is given, and succeeds in bringing an operation, that water must come from somewhere, and this method Dr. Johnston has found to act well in two cases under his charge. One of them exhibited marked improvement from the action of the purgative. His abdomen was distended, and he vomited frequently; but after the large dejections secured by calomel and podophyllin, he recovered rapidly. After ovariotomy, he thinks the large drainage-tubes now in use very much to be preferred to the small ones selected formerly. In one case upon which he operated where the tumor was removed, the attachments were found to extend all through the abdomen, and the large bleeding surface rendered the application of the persulphate of iron in some places a necessity. The large drainage-tube afterwards used permitted the clots formed by it to pass with ease.

DR. D. W. YANDELL, of Louisville, said that he had the deepest conviction that there is no more danger of a man's dying of a gunshot or other wound of the peritoneal cavity properly treated, than there is of a woman dying of an ovariotomy properly performed. That is to say, that ninety per cent. of wounds of the abdominal cavity ought to recover. There can be nothing more certainly misleading, both to the people who are, after all, our auditors, and to the profession, than that statement. Taking the experience of the individual members of this Society, and it will result that out of six cases of gunshot wounds of the abdomen four will die —one of peritonitis, two of hemorrhage, and one of septicæmia. Two will die of hemorrhage, then, and two of something else. Now, in performing ovariotomy we know when and where hemorrhage will probably occur, and we are therefore prepared to meet it. Again, the shock is deeper from a shot wound than from that made by the surgeon's knife, and the wounded person is seen for the first time in that condition. Further than this no man has yet been so wise as to be able to say what course a ball has taken after it has once entered the body, and while he believes it is good surgery to open the cavity, as taught by the master of us all, yet there are many cases in which it is not good surgery; that is to say, here is a man who has had a ball from a Derringer pistol through him, you find him pulseless and cold; under such desperate circumstances Dr. Yandell did not believe it good practice to open the wound.

With cutting wounds it is quite otherwise, the shock is not so great, all about the wound the tissues are puffy, and it is evident hemorrhage is taking place; under those circumstances the indication to open the wound and find the bleeding vessel is plain. He wished to say that the declaration of a great man published in a moment of enthusiasm is misleading; that the state-

ment is not sustained by facts nor likely to be sustained; and that shot wounds are incalculably more dangerous than the knife of the surgeon in operations.

(*To be concluded.*)

CORRESPONDENCE.

ANÆSTHESIA BY THE MIXED METHOD.

To the Editor of THE MEDICAL NEWS.

SIR: In the number of your journal for March 22d, I observe an editorial article upon the importance of anæsthesia by the "mixed method."

During the last six months I have adopted this method with the most satisfactory results.

The following cases will illustrate the important advantages of this late improvement in producing the anæsthetic state:

Case I.—A lady, aged forty-six, with a carcinoma of the right breast, applied for extirpation. Half an hour before proceeding to operate I gave her, subcutaneously, a dose of morphine and atropine. She felt quite drowsy before commencing the administration of the ether, and in less than four minutes was profoundly anæsthetized. The operation occupied considerable time, for the gland was exceedingly large, and the hemorrhage was troublesome. She rallied well, and had comparatively little pain after the operation. No vomiting occurred.

Case II.—A man, aged fifty-two, had his leg amputated for necrosis of the femur. Forty minutes before administering the ether I gave him, subcutaneously, a dose of morphine and atropine, as in the above case. Profound anæsthesia was induced in a few minutes with the utmost facility. No vomiting, delirium, or pain immediately after the operation occurred.

Case III.—A man, aged forty, had both feet badly frozen about three weeks before I was called to see him. As they were quite gangrenous, I decided to amputate before the patient would become weaker. I gave the morphine and atropine subcutaneously, as in the above cases. In fifteen minutes he was sleeping soundly, the first time for several days. A few ounces of ether were sufficient to produce insensibility, and no opium was required after the operation to allay pain.

This meagre record is sufficient to show the great advantages of the mixed method. Some of the strongest objections to ether, which, by the way, is the safest anæsthetic, are now overcome. Administered about thirty minutes after the injection of morphine and atropine, it is rapid in its action and not irritating to the air-passages. A smaller quantity is required, and its effects are less unpleasant.

Yours respectfully,

P. A. MACDONALD, M.D.,
Medical Superintendent of the Marine Hospital, Port Hawkesbury, N. S.

NEWS ITEMS.

DINNER TO DR. ALFRED STILLÉ.—On Thursday evening, June 5th, Dr. Alfred Stillé was tendered, on behalf of the medical profession of Philadelphia, a complimentary dinner at the Hotel Bellevue. The President of the College of Physicians, Dr. Da Costa, presided, and covers were laid for seventy-seven. Among the invited guests present were Drs. Austin Flint, of New York, George C. Shattuck, of Boston, J. S. Billings, of Washington, Charles J. Stillé, of Philadelphia, R. S. Ives, of New Haven, and Traill Green, of Easton. The profession of Philadelphia was represented by its most prominent members.

Upon the completion of the *menu* Dr. Da Costa called the company to order and spoke as follows:

In rising to propose the health of the guest of the evening, I do so with mingled feelings. Joined to the pleasure of the duty, is the sad reflection that the master to whom common consent had assigned the agreeable task, has gone from among us, and that on another has devolved the expression of the kindly sentiments which have brought us here. Most fitting, too, would it have been that he should have presided to-night; for a great man befits a great occasion.

In truth, it is a great occasion which calls us together. When, at the end of a long and distinguished career, those who have labored with or alongside of a man; who have been his pupils, his associates, his colleagues; have striven for the same offices, have vied with him in generous rivalry, voluntarily meet to testify their friendship and to mark their approbation of his life, it is, indeed, a memorable event, not only to him, but to his calling. And we are giving all that we have to give. We cannot bestow on you an order of merit, such as a government in some countries might bestow. No ribbon of the Bath, no ensign of the Legion of Honor, no Iron Cross can be placed on your breast. Nor can we crown you with a civic crown, with its appropriate inscription *ob cives servatos*. Yet your crown of triple oak, accorded to you now by the representatives of your own profession, for a life of valuable services, will be no less a mark of preëminence because it will have to rest invisibly on your brow.

It is difficult, in your presence, to speak of the title you have to this and other distinctions without appearing to violate the canons of good taste. But you must look upon yourself as being with us on an occasion in which your claims are being summed up at the bar of American medicine—claims not alone for to-day, but for posterity; and in which the advocate may plead the more earnestly, because he feels the consciousness of an assured verdict.

Dr. Stillé has been distinguished in various capacities—as author, as professor, as worker for the common good of the profession.

Stillè, the author, has produced works, the learning and style of which are ornaments to American literature, and in whose pages discriminating judgment is as conspicuous as grace of language. The great treatise on *Therapeutics and Materia Medica*, has been described by a foreign journal as a work on medicine of a kind rarely seen, so ponderous in its dimensions, so fascinating in its contents.

Stillé, the professor, has been remarkable for the fulness and accuracy of his discourses; the eloquent denunciation of new names given to old things; the conscientious attempt to keep abreast of the times in an ever-widening subject; the admirable exposition of the matter; the clear, sonorous delivery. In the occupancy, for twenty years, by this scholarly physician, it is certain that a great chair—the chair of Rush, of Chapman, of Wood, of Pepper—has lost nothing of its fame.

As a worker for the common good of the profession, the efforts in the cause of medical education, the active interest in societies, recognized by having been chosen to the position of President of the County Medical Society, of the Pathological Society, of the American Medical Association, and, recently, of the College of Physicians, are conspicuous. It is not the least of his claims that he was very prominent, none more so, among the founders of the body which has done so much to bring the medical profession into unison—the American Medical Association. Nor must the generous giving of the bulk of his large library to the ancient University with which his name is indissolubly connected, remain unmentioned among his public-spirited acts. Many an aspiring student will become a lover of literature and of science through the thoughtful gift of this lover of books.

But, sir, it is not the author, the teacher, the worker for public objects only, whom we hold dear. If your titles were these alone, however much we might respect them, we should scarcely be here to honor you to-night. Better than Stillé the author, better than Stillé the teacher, better than all, is Stillé the man. No meretricious schemes to make gold jingle in soulless pockets attach to your name. A life of probity, a high sense of honor, uniform courtesy, have endeared you to us.

Such, then, are some of the titles to recognized distinction, in and out of American Medicine, which we gladly claim for you. That Medicine is now making for itself a more and more individual position. In every country there are those who are born old, and remain with eyes turned back to the past. Knowledge has no charms for them unless she is in wrinkles, and her joints creak, and her utterances are wheezy. There are those who stay as children, restless, full of enthusiasm, stumbling over everything, and eager for every change. Our national character furnishes but few of the former; and the traits of the latter are very greatly modified by what, besides quick perception of the useful, is a peculiarity of American Medicine, its thoroughly cosmopolitan nature. With the exception, perhaps, of one country, medicine is here more cosmopolitan than anywhere. And there is a growing love of original research, an increasing appreciation of pure literary work—as shown in the enthusiastic reception of the wonderful volumes in which brigades of folios, divisions of octavos, and army corps of pamphlets, are being placed into line under the direction of a marshal who is with us to-night—which bespeak a bright and most active future.

But it must be confessed that, as yet, some of this love of work, with the desire to instruct which comes with it, takes doubtful means of expression. For the advancement of the profession, it does not seem absolutely necessary that wherever a railroad opens a new country, and a prosperous little town attracts eight doctors, there should be at once two medical schools. Nor is it clear why the establishment of every post-office should quickly be followed by a fresh medical journal. And in these journals it is a little trying to him who endeavors to keep himself informed of the literature of the day, to find in six out of ten, articles to prove that opium will make you sleep, and is dangerous if too much be taken; that castor oil has purgative properties, and is not relished, especially by children; that it is difficult to prescribe for malarial diseases without using quinine; and that aloes is bitter and may gripe very unpleasantly. One might pardon some neglect in these lively authors to let their overflowing plethora of knowledge run off into the common stream.

Yet these are, after all, but temporary drawbacks in that great development which we all of us see so clearly, and hail with so much pleasure.

Honored guest: Be it in connection with the Medicine of our country, or, better, as a summary of your whole career, it seems not inappropriate to apply to you the words of Cicero: "*Omnia summa consecutus es, virtute duce, comite fortuna.*" If you have attained the highest rank, with virtue leading the way and fortune attending, it will so remain to the end. During the many years of vigorous life which we fervently hope are still before you; wherever you elect to pass these years, whether in the seclusion of your home and in lettered ease, or in visiting the scenes of former travel and early studies; in whatever clime; whatever skies may cover and sun shine on your path—with you will be the affectionate regards of those who surround you to-night, and of the far larger body of which we are only the temporary representatives; and you may know and feel that hundreds are joining now, and will always join us, in the wish: "Health and long life to Professor Alfred Stillé."

DR. STILLÉ, on rising, was greeted with prolonged and enthusiastic applause, and he spoke as follows:

Mr. Chairman and Gentlemen: The cordial welcome you have given me on this occasion, which I regard as one of the most important events of my life, and the terms in which you have expressed what you conceive to be the judgment of my professional brethren, would give me unalloyed pleasure were it not that I miss from this company the one to whom I am proud to acknowledge my debt for so great a distinction. He has gone to his endless rest, venerable for his years and resplendent with honors nobly won. I should be unjust to my own feelings did I fail to do that homage to his memory which is the only return it is possible for me to make for a long series of acts which were among the most grateful of all the commendations that my professional life received.

You, Mr. Chairman, have mentioned some of the posts of trust and honor confided to me at different times. All of them I owe to the unsolicited favor of my medical brethren, and I am proud to acknowledge it as the making of my history. Whatever I might have attempted, I should have achieved but little without their encouragement and approbation, and certainly never should I otherwise have reached that period of serene retrospection and repose which is the evening of a happy and not uneventful professional life.

This goodly company, these cheerful and hearty greetings, these glowing lights and festive ornaments that attend my retirement at the appointed period of three score years and ten, appear to me like the flowering of the plant that is fabled to bloom but once in a century, for all else in my professional career seems tame by comparison. The column, such as it was, that I endeavored to construct and rear in the temple of Esculapius has to-night been crowned with a capital on which is lavished all the elaborate ornamentation of the Corinthian style. I can only hope that the plainness of the structure will do no injustice to the richness of the decoration.

In looking from this eminence adown the road I have travelled since entering upon my professional studies, it is impossible for me to doubt that in men's lives apparent accidents may determine their course and issue. While still a medical student two of my fellow-townsmen returned from abroad glowing with the fire they had caught in Paris, the then acknowledged centre of medical science. Gerhard and Pennock were the apostles of the school of observation under whose preaching I became a zealous convert. As soon as it was possible I hastened to the enchanted scene of their European labors, to be stimulated still further by the recent memories of Jackson and Bowditch, and Holmes, of Boston, and to enjoy the salutary companionship of Dr. Shattuck, of Boston, who still survives, and is at my side to-night to do honor to his old friend and to your invitation. And there is still another before me, venerable in all that pertains to old age except its weaknesses—Medical Director Ruschenberger, U. S. N.—with whom I, at the end of two years, made my homeward voyage of six weeks' duration, and cemented a friendship that has survived the test of *tempus edax rerum*. It is not often given to a man to revive associations such as these, nor to feel that Time, which destroys so much, yet sometimes spares what is best in our experience of mankind.

During one of my summer holidays, while abroad, it was my lot—less vulgar then than now—to climb the Alps and observe the expedients used by the mountaineers in ascending the icy peaks. I noted the laborious industry with which they cut for themselves footholds on the slippery steep, and so mounted slowly but steadily to their destination. This method profoundly impressed me at the time, and I said to myself, "Surely in such wise must one hew his way to fame and fortune; and whether the point to be attained be the highest peak of all, or only some humbler hill-top by the way, it was clear that whatever else might win, *improbus labor omnia vincit*." What seemed revealed to me then among the sublime solitudes of nature, has been echoed by a thousand voices along the whole pathway of my life. It came to me also, like a voice from the tomb, in the words of an old family motto, *Innocenter, patienter, constanter*, and it was repeated in the history of all the men I have known who secured for themselves a steadfast place in their day and generation. I cannot doubt that in the bosom of every one who hears my voice there is felt a silent attestation of its truth. It has been the keynote of my teaching as well as the guide of my actions, and, therefore, how little soever of the good that has been attributed to me by your partial voices may in reality be mine, I owe it all to the lesson of steady industry and undaunted perseverance that I learned from the Alpine mountaineer.

And now let me simply add that "the crown of triple oak" which you crowned me withal to-night, will preserve its freshness through the remainder of my life, and will be preserved by those who succeed to my name as more precious than gold or jewels or any material badge of honor.

In response to the toast of "Our guests from abroad, who have honored us by their presence," DR. JOHN S. BILLINGS, U. S. A., said:

Permit me, in the first place, to express my high appreciation of the honor of being called on to respond for "the guests" on such an occasion as this. I do not, however, return thanks for the distinction, because there are good grounds for difference of opinion as to whether it is a matter to be thankful for, and one is apt to rise under such circumstances with something of the feelings which a very worthy man attributed to his wife who had died of consumption. Being asked by a sympathizing friend whether she had been resigned to the parting, he said, "Resigned! Why of course; certainly. She had to be."

In the second place, I wish to assure the "guests" of my sympathy in the regrets which each of them is about to feel when he hears his sentiments so poorly expressed, and when he thinks of what he would have said had he been in my place. Here, for instance, is our friend, Dr. Flint, who would have told you how all good New York physicians reverence Philadelphia for its conservative dignity in medical matters, low fees possibly excepted, and how glad they are to do honor to your general superiority by joining in this tribute to one of your most distinguished representative medical men.

I think I can even now see in our friend's face signs of regret that he did not accept the request to speak, as he thinks of how he might have impressed you with these sentiments.

However, the important uses of such dinners as these do not greatly depend upon the formal speeches. These last are, or at all events may be, very good things for those who listen to them, especially if their diaphragms are made to rustle a little, but we know pretty well what must be said in connection with the different toasts. The speaker is somewhat in the position of the rabbit which a certain western Munchausen declared was so hard pressed by his dog that he climbed a tree. "What!" said an incredulous listener, "a rabbit climb a tree." "Well," said Munchausen, "you see he was obleeged for to climb."

But the great use of such gatherings is in the civilizing and harmonizing influence which they have on those who attend them through the opportunities which they afford for making acquaintances and informal conversations.

A very large part of the unpleasantnesses of this world is due to people who are not found at social dinners. And of all gatherings of this sort it seems to me that such a one as has brought us here to night is among the pleasantest. Personal interests and ambitions are for the time being put aside and forgotten, and we join in honoring a man who has made his mark and won his place. It is a great privilege to be a guest upon such an occasion, and I am speaking for all your guests when I say that it is a privilege which in this special case we highly appreciate, and for which we return our sincere thanks.

To all physicians in this country Dr. Stillé's name is familiar, as that of a clear-headed, sensible speaker and writer who has observed and thought for himself, and at the same time has made extensive use of the resources of medical literature. He is one of the first American medical bibliographers. For these, and for other reasons which have been set forth by previous speakers, and because he has not written or spoken except when he really had something to say; because, also, we recognize his personal worth—the readiness which he has always displayed to promote the interests of Medicine

—we, your guests, hold ourselves as specially fortunate in being able to be present to indicate our appreciation of this rare combination, and to enjoy the great pleasure of meeting with our Philadelphia friends, so many of whom to most of us are almost like members of our own family.

DR. GEORGE C. SHATTUCK, of Boston, then said: I recognize, Mr. President, your kindness in inviting me to be present on this most interesting occasion, and to be an observer and a listener. Since coming into the room, I received an intimation that it had been assigned to me to say a few words as the intimate friend of Dr. Stillé. Now, we in Boston look up to Philadelphia as the medical metropolis, and then, though we are accused of thinking much of ourselves as the "Hub," yet we have lately been somewhat taken down. One of our *solid* men was missed from his place at an insurance office, and on returning after an interval of some days, was asked, "Where have you been, what are your experiences?" "Why, I have been," was the answer, "in the city of Chicago, and being introduced into a place like this, where many congregate, I was asked where I came from. On answering, Boston, one after another said they had never heard of the place, and finally one replied, 'I think I have heard of a small village somewhere on the coast of New England with that name.'" So I must thank you again for allowing one from so obscure a place to say a word in this assemblage of the medical men of Philadelphia.

Nearly fifty years have passed since Dr. Stillé and I were fellow-students and intimate friends. We were looking forward to our future life, professional and social, with anticipations of success, picturing what might be in store for us. And though the lines of our Boston professor of anatomy may be repeated by us, and we may say,

> "Where, oh! where are the joys of the morning,
> The hopes that illumined youth's prime?
> Gone, like tenants that quit without warning,
> Down the back-entry of time."

Yet how thankful should we be that our friend has been able to lead a life in accordance with many of his brightest hopes. He had a high ideal. His aspirations were for "whatsoever is true, whatsoever is honest, whatsoever is of good report," and he has led a life of devotion to duty, of successful, unremitting toil in reference to the good of all to whom he was called to minister. As a practitioner of medicine, as a teacher of medicine, as a writer on most important matters, how much good has he done; what an example has he given! In all, how mindful has he been of others, how steadily has he set aside self and selfishness, and kept before him his duties to others. A recent writer has remarked that in this country the individual is too prominent, self-exaltation and advancement are so much the motives to exertion. Our duty to work for the family, the State, the profession, is not sufficiently recognized. But we are met to-night to do honor to one who has worked for the profession, and who, in a life of many years, has striven to raise the tone of the profession, and to work and to store up knowledge for the benefit of others, that the whole medical profession may be the better for his labor and his acquisitions.

To excel in learning and in the communication of knowledge may be highly prized, for to many such talents are not given. And my friend is to be congratulated for having tried so well, and for receiving such tokens of the appreciation of his efforts from associates and friends of so many years. I am sure I join heartily in the good wishes for a prolongation of life, and of his powers of usefulness. We must all recognize that old age has its peculiar duties and responsibilities, and whilst we congratulate him at having accomplished so much, and at having so well earned a season of rest and repose, we must express a hope for continuance of life, for preservation of bounties; for we cannot spare him yet; his old friends are not yet done with him, nor can they consign him to inactivity and oblivion.

DR. AUSTIN FLINT being called upon, said:

Mr. President and Gentlemen: I am perfectly sincere in saying that I did not expect to be called upon to say anything to night. Feeling safe in this respect, I have enjoyed the dinner without any drawback. I am, moreover, glad to have the opportunity to express orally my heartfelt thanks for the invitation to be present on this occasion. I esteem it a great privilege to be permitted to join in expressing to our honored guest our appreciation of the services which he has rendered to medical literature by his valuable contributions, of his services in behalf of medical education by his teachings as a professor of medicine, and of the benefit which he has conferred on the medical profession by the purity of his professional and private life.

I congratulate him cordially on his retirement from his arduous professorial duties. Trusting that he may long have life, health, and vigor, I will express the hope that his pen will not be idle, and that we may expect from him further valuable contributions to American medical literature.

It was my good fortune to be a guest at a dinner in this place somewhat over a year ago, on an occasion of which I shall always cherish the most grateful recollection. On that occasion, the seat which I occupy to night, was occupied by one whom we all miss on the present occasion. I should not make this allusion if I supposed it would cast a gloom over this meeting. It should not. The departure to another world of one ripe in years, who has lived a useful life, and who goes laden with those riches of the mind and heart, which, as we may believe, are carried beyond the grave, is not to be regarded in the light of a calamity, except as regards the deprivation of those who remain. It is pleasant to think that, although of the body of our beloved friend only his ashes are left with us, he still lives, and that he may be in some way cognizant of the events in this world. He may be cognizant of this meeting, and, if so, I know from my intimate friendship for many years, that he yearns to make known to us how thoroughly he is in sympathy with our present enjoyment, and with the special object which has brought us together.

After a few remarks by Dr. Pepper, and the reading of a number of letters of regrets from invited guests who were unable to be present, "the loving cup" was passed, and the festivities were concluded.

BRUNSWICK, ME.

(From our Special Correspondent.)

MAINE MEDICAL SCHOOL; GRADUATING EXERCISES AT BRUNSWICK.—The close of the sixty-third course of lectures was marked by more formal exercises than customary, and by the first annual meeting of the Alumni.

The graduating exercises in Memorial Hall, at 9 o'clock A.M., consisted of an address by Prof. S. G. Brown, of Bowdoin College (late of Hamilton), a parting address by a member of the graduating class, the presentation of diplomas by the President of the College, Prof. Packard, and singing of a class ode. At noon occurred the first annual meeting of the Alumni, and notwithstanding a heavy rain-storm, members were present from all over New England.

The President, Dr. F. C. Thayer, of Waterville, congratulated the Association upon having made itself an assured success, and alluded briefly to the purpose for which it was organized—to coöperate with the Faculty and government of the School in securing its material advancement by enlarging its clinical facilities, through a change of location. An addition is needed to the chairs of instruction, and the Alumni were urged to lend their cordial aid in bringing about these desired improvements, by establishing an Alumni Fund. A committee was appointed to consider these recommendations, and subsequently reported in favor of the appointment of a committee to confer with the Faculty of the School, and report at the next annual meeting of the Association.

The President appointed Dr. O. A. Horr, of Lewiston; Dr. E. M. Fuller, of Bath; and Dr. H. H. Hunt, of Portland.

The Nominating Committee reported, recommending the reëlection of the present officers, as follows:

President.—Dr. F. C. Thayer, of Waterville.

Vice-Presidents.—Dr. S. Laughton, of Bangor, and Dr. R. D. Bibber, of Bath.

Secretary.—Dr. C. D. Smith, of Portland.

Treasurer.—Dr. F. H. Gerrish, of Portland.

Dr. A. F. Fuller, of Bath, then delivered an address, at the close of which the meeting adjourned, and, with invited guests, to the number of one hundred and eight, sat down to a banquet in the lower hall.

The afternoon was passed by the members in visiting the medical building, the Seavy Anatomical Cabinet, and the various college buildings. During the evening, the class of 1869 held a reunion at the Tontine Hotel.

The attendance upon the meeting far exceeded the most sanguine expectations, scattered as the graduates of this school are over all sections of the country. The Association is now firmly established, and all graduates to whose notice this may come are earnestly requested to join hands in promoting the prosperity of the School and the fraternity of the graduates.

Any information relative to the alumni, such as correct address, death, change of location, or applications for membership, may be forwarded to the Secretary, Dr. Charles D. Smith, 17 Brown Street, Portland, Me., and the interests of the Association will be thereby greatly promoted.

HOSPITAL COLLEGE OF MEDICINE.—The annual commencement of the Hospital College of Medicine of Louisville was held on May 29th. The degree of M.D. was conferred upon thirty-one graduates.

AMERICAN NEUROLOGICAL ASSOCIATION will hold its tenth annual meeting in the Hall of the Academy of Medicine on June 18, 19, and 20. The following papers are promised: "On Encephalic Nomenclature," by Dr. Burt G. Wilder; "A Study of the Etiology of Tabes Dorsalis with Special Reference to the Efficiency of Syphilis," by Dr. E. C. Seguin; "Basedow's Disease," by Dr. A. D. Rockwell; "Can Locomotor Ataxia be Cured?" by Dr. G. M. Hammond; "Multiple Neuritis," by Dr. S. G. Webber; "A Case of Word-deafness and Blindness, without Paralysis," by Dr. R. W. Amidon; "The Effect of Injuries of the Spinal Cord upon the Excretion of Carbonic Anhydride," by Dr. Isaac Ott; "A Contribution to the Study of Hysteria as Bearing on the Question of Oöphorectomy," by Dr. G. L. Walton; "Typical Hysterical Symptoms in Men due to Injury, and their Medico-legal Significance," by Dr. James J. Putnam.

NEW JERSEY STATE MEDICAL SOCIETY.—At the annual meeting of this Society, held at Cape May, on June 10th and 11th, the following officers were elected for the ensuing year:

President.—P. C. Baker, M.D., of Morristown.

Vice-Presidents.—Drs. Joseph Parrish, of Burlington; Charles J. Kipp, of Newark; and J. W. Ward, of Trenton.

Corresponding Secretary.—Dr. William Elmer, Jr., of Trenton.

Recording Secretary.—Dr. William Pierson, Jr., of Orange.

Treasurer.—Dr. W. W. L. Phillips, of Trenton.

PUBLIC BEQUESTS OF THE LATE PROF. S. D. GROSS.—The will of the late Dr. Gross has been admitted to probate, and contains the following public bequests:

"I give and bequeath my medical library, my museum, and diagrams, to one of the following institutions: The Jefferson Medical College, or the Philadelphia Academy of Surgery, or the College of Physicians of Philadelphia, the choice of said institution to be made by my executor, in his free and uncontrolled discretion; provided, however, that such institution so accepting shall furnish a fire-proof apartment for my medical library and shall call it the Samuel D. Gross Library. If the institution so chosen does not accept this bequest, then I leave it to one of the following: The University of Pennsylvania or the New York Academy of Medicine; also to be made at the selection of the executor, and with the same provision as above.

"I give and bequeath to one of the following institutions—The Jefferson Medical College of Philadelphia, Academy of Surgery, or College of Physicians of Philadelphia, the choice of said institution to be made by my executor in his free and uncontrolled discretion—the sum of $5000, the principal of which is to be invested by said institution as a permanent fund, and the accumulated interest or income therefrom arising to be paid every five years to the writer of the best original essay, not exceeding 150 printed pages octavo in length, illustrative of some subject in surgical pathology or surgical practice founded upon original investigation; the candi-

dates for the prize, which is to be called the Samuel D. Gross Prize, to be American citizens."

In a codicil he provides "That all my medical books, with the exception of those mentioned in my will, and also my office bookcases, be given to the Philadelphia Academy of Surgery, in trust, to be held by it so long as it shall exist as an independent and distinct organization. At the end of that time I decree that they shall be given to the College of Physicians of Philadelphia, or to any respectable or permanent institution that the Academy may select for the purpose, my children, if any survive, also having a voice in the choice."

The executor, Mr. A. Haller Gross, has tendered, under the terms of the will, the library and prize to the Philadelphia Academy of Surgery, and this body has accepted the trusts, and has arranged with the College of Physicians of Philadelphia for the deposit of the books in the Library of the College to be used in accordance with the general rules governing the College Library.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION will hold its next meeting in Springfield, Illinois, in September, 1884.

THIRD CONGRESS OF THE ITALIAN SURGICAL SOCIETY.—The third Congress of the Italian Surgical Society will be held in Turin on the 15th to the 20th of September, 1884. The secretaries are DRS. G. NOVARO and G. BERRUTI, of Turin.

NEW JOURNALS.—Three new periodicals have recently appeared in Madrid. The *Archivos de Ginecologia y Enfermedades de la Infancia* is a monthly; the *Diario Medico-farmaceutico* appears every four days; and *Dr. Sangrado*, a satirical review, has appeared every fifth day since November.

DR. ROBERT KOCH.—A newspaper sketch of the distinguished discoverer of the bacillus of tubercle and of cholera, describes him as a man of medium height, thin, gray-haired, with a serious, spiritual countenance. He looks much older than he is—forty-one.

THE DWIGHT INSURANCE CASE.—A telegram from Norwich states that the Mutual Benefit Life Insurance Company of New Jersey, has just paid the two policies of insurance of $5000 each, which were taken out by the late Col. Walton Dwight.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 3 TO JUNE 9, 1884.

THE ARMY MEDICAL EXAMINING BOARD, New York City, is dissolved, to take effect June 14, 1884.

BROWN, JOS. B., *Lieutenant Colonel and Surgeon.*—Upon completion of the business of the A. M. B., directed to comply with S. O. 44, current service, A. G. O., and return to New York City.

CLEMENTS, BENNETT A., *Major and Surgeon.*—Directed to await orders in New York City.

KIMBALL, JAMES P., *Captain and Assistant Surgeon.*—Granted leave of absence for two months and fourteen days, to take effect June 14, 1884, and ordered to relieve, August 28, 1884, Captain Robert H. White, Assistant Surgeon, from duty at U. S. Military Academy, West Point, N. Y.

CAPTAIN WHITE, on being relieved, ordered to report in person to the Commanding General, Department of California, for assignment to duty.

STERNBERG, GEO. M., *Major and Surgeon.*—Relieved from temporary duty in S. G. O., and ordered to assume the duties of Attending Surgeon and Examiner of recruits, at Baltimore, Md.—*S. O. 131, A. G. O.*, June 6, 1884.

FINLEY, J. A., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Stockton, Texas, and assigned to duty as Post Surgeon, Fort Concho, Texas.—*Par. 4, S. O. 69, Headquarters Department of Texas*, June 2, 1884.

MOORE, JOHN, *Lieutenant-Colonel and Assistant Medical Purveyor.*—Ordered to perform, in addition to his present duties, those of Medical Storekeeper, San Francisco, Cal.

JOHNSON, HENRY, *Captain and Medical Storekeeper.*—Relieved from duty at the Medical Purveying Depot at San Francisco, Cal., and ordered to report for duty at the Medical Purveying Depot, New York City, relieving Captain Andrew V. Cherbonnier, Medical Storekeeper.

CAPTAIN CHERBONNIER, on being relieved by Captain Johnson, will proceed to St. Louis, Mo., and report in person to Captain Geo. T. Beall, Medical Storekeeper and Acting Assistant Medical Purveyor, for duty at the Purveying Depot at St. Louis, relieving Captain Beall of his duties as Medical Storekeeper.—*Par. 9, S. O. 128, A. G. O.*, June 3, 1884.

FRYER, BLENCOWE E., *Major and Surgeon.*—Granted leave of absence for one year, from July 1, 1884.—*Par. 7, S. O. 128, A. G. O.*, June 3, 1884.

HALL, JOHN D., *Captain and Assistant Surgeon.*—Granted leave of absence for three months, to take effect on his arrival at St. Paul, Minn.—*Par. 8, S. O. 128, A. G. O.*, June 3, 1884.

HEGER, ANTHONY, *Major and Surgeon.*—Assigned to duty at Fort McHenry, Md., as Post Surgeon.—*Par. 1, S. O. 108, Headquarters Department of the East*, June 2, 1884.

HUNTINGTON, DAVID L., *Major and Surgeon.*—During the absence of the Surgeon-General, directed to take charge of the Office of the Surgeon-General and perform his duties.—*Par. 6, S. O. 129, A. G. O.*, June 4, 1884.

BENTLEY, EDWIN, *Major and Surgeon.*—Assigned to duty at Fort Clark, Texas, as Post Surgeon.—*Par. 1, S. O. 68, Headquarters Department of Texas*, May 31, 1884.

KOERPER, EGAN A., *Captain and Assistant Surgeon.*—Assigned to duty at Fort Keogh, M. T.—*Par. 1, S. O. 58, Headquarters Department of Dakota*, May 27, 1884.

BARNETT, RICHARDS, *Captain and Assistant Surgeon.*—Now on sick leave of absence, is relieved from duty at Columbus Barracks, Ohio, and ordered to report to Commanding General, Department of the East, for assignment to duty.—*Par. 2, S. O. 129, A. G. O.*, June 4, 1884.

CUNINGHAM, T. A., *Captain and Assistant Surgeon.*—Ordered to relieve Assistant Surgeon C. B. Byrne, U. S. A., from duty at Fort Lewis, Col. Assistant Surgeon Byrne, when so relieved, ordered to proceed to Fort Gibson, I. T., and report to the Post Commander for duty.—*Par. 2, S. O. 112, Headquarters Department of Missouri*, June 4, 1884.

BANISTER, J. M., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for one month and seven days, to commence June 13.—*S. O. 22, Headquarters Division of the Atlantic*, June 5, 1884.

MCCREERY, GEO., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for two months with permission to apply to the Adjutant General of the Army for two months extension.—*Par. 3, S. O. 56, Headquarters Division of Missouri*, June 5, 1884.

WILSON, GEO. F., *First Lieutenant and Assistant Surgeon.*—Relieved from temporary duty at Fort Canby, Washington Territory, and ordered to return to his proper station (Fort Walla Walla, Washington Territory).—*Par. 2, S. O. 70, Headquarters Department of Colorado*, May 26, 1884.

OWEN, WM. O. JR., *First Lieutenant and Assistant Surgeon.*—Having reported at these Headquarters in compliance with Par. 5, Department Special Orders, No. 62, current series, will return to, and take station at Fort Stevens, Oregon.

In addition to his duties at Fort Stevens, Assistant Surgeon Owen will perform those of Medical Officer at Fort Canby, Washington Territory.—*Par. 1, S. O. 70, Headquarters Department of Colorado*, May 26, 1884.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL ARTICLES.

A PLEA FOR MORE HEROIC SURGICAL INTERFERENCE IN AFFECTIONS OF THE BRAIN.[1]

BY R. W. AMIDON, M.D.,
OF NEW YORK.

THE question must arise in the mind of one watching the progress of medical science and practice, Why is it that since Broca, in 1871, guided by well-determined anatomical and physiological laws, trephined a paralyzed aphasic over the centre for speech and greatly relieved the symptoms by evacuating a cerebral abscess, Why is it, that in the succeeding thirteen years, similar operations scientifically planned and executed, are so seldom performed, and they hardly reach a score. One answer, perhaps the chief one, lies in this fact, that probably neither before nor since has there been joined in one man such anatomical and physiological knowledge of the nervous system, with such surgical skill and daring as existed in the lamented Broca. He was a man who devoted his time *entirely* to science, study, laboratory work and his hospital service; early every morning he spent hours in his wards at Hôpital Necker, encased in a black cambric gown, ready for anything, followed always by a throng of eager students.

It was he who localized the centre for articulate speech, thus opening up the wonderful realms of cerebral localization; it was he who first accurately pointed out the relations of certain important cerebral convolutions to fixed external landmarks, thus making the brain visible through its opaque envelopes, and it was he whose hand, guided by these scientific data, drove the trephine directly toward a hidden cerebral abscess.

Surgeons may well admire his daring, neurologists his learning. That such an example has almost fallen to the ground in the past thirteen years cannot be attributed to inaction, for, during those years, surgical science has made wonderful onward strides, nor have physiologists allowed the expanse of the cerebral cortex to remain unexplored, but specialism has compelled the surgeon to neglect his study of cerebral anatomy and physiology while the neurologist, even if he possess the requisite surgical skill, lacks the material upon which to test his knowledge. Deplorable indeed is that overfine subdivision of practice which allows *one* physician to cling to obsolete methods, *another* to soar in a cloud of unproven theories, while the poor patient gets well if he can.

Another very serious drawback to the advance of cerebral surgery has been the tenacity with which surgeons have clung to the idea that trephining of itself is a dangerous operation. To prove that penetrating the envelopes of the brain is *not* a dangerous operation, will occupy the first and larger part of this paper, for this proved will remove the greatest objection that can be offered to more heroic cerebral surgery.

The operation of trephining is very old, and is practised by all races. In France, among débris belonging to the neolithic age, with vessels, utensils, and weapons of stone, are found skulls having smooth, oval, and bevelled edged holes, which were undoubtedly made during life and for a special purpose.[1]

For an operation of such extreme antiquity accurate data as to its safety are extremely meagre. Our modern treatises on surgery are surprisingly wanting in statistics. Judging from their figures, the operation is indeed a dangerous one, its mortality varying, according to them, from forty to seventy-five per cent. The deductions one would naturally draw from these statements and figures are fallacious, for the reason that many of these deaths occurred from lesions which antedated the operation, lesions which would of themselves have ultimately caused death. They do not attempt to ascertain in what percentage of cases the operation excites the fatal issue.

The nearest approach to an estimation of the exact mortality of the operation appeared in *St. Bartholomew's Hospital Reports* for 1882, vol. xviii. p. 213. In an article entitled "Is trephining the skull a dangerous operation *per se?*" Dr. Walsham has looked up and analyzed six hundred and eighty-six cases in which, for different purposes, the cranial cavity has been opened or explored, not using the word "trephining" in its strict sense. Of these six hundred and eighty-six, four hundred and seventeen survived, showing thus a mortality of 39.3 per cent. He divides these cases into five classes: First, preventive trephining, in which there were no cerebral symptoms, but in almost all a compound fracture of the skull existed. Here the mortality was 21.9 per cent. Second, immediate curative trephining, in which severe cerebral symptoms existed. Here 48.4 per cent. died. Third, intermediate curative trephining, in which cerebral symptoms were present. Here twenty-seven per cent. died. Fourth, delayed trephining where generally inflammatory symptoms had set in. Here 58.5 per cent. died. Fifth, late trephining, in which 22 per cent. died.

Of the latter class, in which there were not at the time of operating any symptoms liable to prove fatal, there were over eighty cases in which no wound existed in the head at the time; of these 14.4 per cent. died, and of forty cases in which there was a fistulous track leading down to dead bone or a purulent collection within the cranium, only 2.5 per cent. died.

He thus estimates that in one hundred and twenty-two cases of late trephining, in which there was present at the time no condition endangering life, only 10.6 per cent. died.

[1] Read before the New York Academy of Medicine, June 5, 1884.

[1] Prunieres, Bull. de la Soc. d'Anthropol., de Paris, 1878, p. 420.

In a later article (*St. Bartholomew's Hospital Reports* for 1883, vol. xix. p. 127, "On trephining the skull in traumatic epilepsy,") he cites eighty-four cases, of which seventeen died, showing a mortality of 20.2 per cent. But he adds that if we except deaths following too long after the trephining to be attributed to the operation, we would see that here too the mortality would be reduced to about 10.6 per cent.

The fairness of Walsham's deductions no one reading his article can doubt, but favorable as his figures are as compared with those of succeeding writers, I think that his percentage of 10.6 as the mortality of the operation *per se* is too high, and I base my statement on the following fact, viz., that while his tables contain *very many* recent cases, they contain more cases which antedate antiseptic surgery. No one for a moment doubts that since the introduction of Listerism, fatal results follow accidental or surgical traumatism much less frequently than before. Particularly is this the case in wounds involving bone. For this reason Walsham's tables are not exact exponents of the results of modern surgery.

In the last few days I have collected one hundred cases in which trephining or kindred operations about the head have been performed for various causes, taking care to select cases treated and reported since 1879, since Listerism has come into general use. Not, however, confining myself to cases in which the Lister dressing was used.

These cases I have not subdivided into classes, as did Walsham, but have tabulated so as to show the injury or pathological condition present, the prominent symptoms preceding and following the operation, the kind of operation and its findings, the dressing or subsequent treatment of the wound, and the final result. From these data it has been possible for me to arrive at pretty conclusive evidence as to the mortality of the operation *per se* as looked at in the light of modern surgery.

Of these one hundred cases taken just as they came in medical journals, since 1879, twenty-six died. Of these twenty-six, twenty-three presented, at the time of operation, symptoms endangering life, thus leaving only three cases in which the fatal issue could even remotely be traced to the operation.

As this percentage seems extremely low and would render the operation as now conducted practically harmless, it may be well to summarize the reasons for rejecting the twenty-three deaths as independent of the operation.

In six cases symptoms of abscess of the brain declared themselves before the operation was performed. In four a meningitis existed at the time of operation. In four cases shock caused death; one died of hemorrhage from a branch of the middle meningeal artery (not wounded in the operation); one died of hemorrhage from the middle cerebral artery, severed by a stab-wound of the head; one died of hemorrhage from a lacerated longitudinal sinus; one of galloping consumption, which was hereditary; one of extensive laceration of the brain; one of opium poisoning; and three I accept, on authority of the physician reporting them, as not dying from the effects of the operation. The cases in which the operation seemed to cause death being so few, will be mentioned more in detail.

The first was one reported by Sylvestrini.[1]

The subject was a male, of fifteen, who received the kick of a horse in the right temporo-frontal region. Two months after the injury the boy had a temporary right hemiplegia. Five months later paralysis of the right arm and leg and the lower part of the right side of the face came on. This was accompanied by right hemiepilepsy and complete aphasia, incontinence of urine and feces. Sylvestrini trephined over the centres for the upper and lower extremities, and extracted piecemeal a hard, organized clot, three centimetres in diameter by one thick. Death occurred on the fourth day. On autopsy, there was found to have been a purulent meningitis and two abscesses of the brain, one at the foot of the ascending frontal convolution, and one under the inferior extremity of the fissure of Rolando.

There is a doubt as to whether the operation in this case had, after all, much to do with the fatal result. The symptoms preceding the operation were certainly of a very grave nature, and, considering their slow formation, the cerebral abscesses may well have existed before the operation, in which case the facial paralysis and aphasia could very easily be accounted for, and the fatal issue explained. Still, in the operation of removing an organized clot from an otherwise healthy brain, sufficient violence might have been done the parts to excite the fatal suppurative inflammation.

The second case in which the operation may have caused death is reported by Briddon.[2]

The subject was a male, of sixty-one. A brick fell on his head, causing a compound depressed fracture, four centimetres long, a little to the right of the vertex. The depressed bone was removed, and the margins of the wound were smoothed with a rongeur. The wound was dressed with *proof spirit*. On the third day after the operation the patient had a chill, fever, headache, and photophobia. On the sixth day vomiting and stupor occurred. On the eighth day the dura mater was incised, and a little pus and blood evacuated. On the ninth day there was a chill, with involuntary evacuations, twitchings of the face, and death. On autopsy, there was found a false membrane adherent to the left hemisphere, and an accumulation of greenish pus in the arachnoid.

The fatal issue, if it did not arise from natural and unavoidable causes, *might* have come from the surgical dressing in this case. But the injury itself—so apt to excite fatal intracranial inflammation—may alone be responsible for the fatal result. Certainly the operation, promptly, neatly, and judiciously performed, did not cause death.

The third case is that reported by Noyes.[3]

A male of nineteen received the entire breech-pin of an exploding gun in his right orbit. The breech-pin was afterward found to have projected four centimetres through the roof of the orbit into the right frontal lobe of the brain. The boy was insensible four days, but soon recovered almost perfectly, with the exception of

[1] Bull. de l'Acad. de Méd. de Paris, 1883, 439.
[2] N. Y. Med. Journ., 1879, xxix. 309.
[3] Amer. Journ. Méd. Sci., 1882, lxxxiv. 45.

a destruction of the right eye, and a fistulous track which led down to the foreign body. It was not dreamed then that it had penetrated the brain. The foreign body was found and much force was required to dislodge it from the roof of the orbit and brain.

Sixteen days later, left hemiparesis and other symptoms led to trephining about 7.5 centimetres above the right external angular process of the frontal bone, the supposition being that a secondary abscess had formed there. About twenty cc. of dark purulent matter were evacuated by an aspirator needle. A probe and drainage-tube were passed through the brain to the opening in the roof of the orbit. This was syringed out with a four per cent solution of boracic acid. On the twenty-seventh day there was double optic neuritis (tendency to choked disk having been previously noticed). On the thirty-seventh day the finger was passed eight centimetres through the roof of the orbit, and the brain found badly disorganized. Death occurred on the thirty-ninth day after the operation, and the sixth month after the injury.

On autopsy there was found an immense cavity in the right frontal lobe, but neither this nor the external wounds communicated with the subdural cavity.

There was a basilar meningitis, or, as the author puts it, "a sero-purulent, yellowish-green exudation into the meshes of the pia mater, most abundant over the medulla oblongata, pons, interpeduncular space, and inner parts of the fissures of Sylvius. This exudation is as much on one side of the brain as the other, and does not extend to the convexity."

In this very interesting case the surgical interference probably hastened the fatal issue. It was stated in the history of the case that one day there was discharged from the orbital opening a membrane which had doubtless formed an encapsulating sheath for the part of the foreign body which projected into the brain. For this reason, and because of the absence for so long a time of any cerebral symptoms, it is possible that this boy might have lived for years. It would seem, however, that the basilar meningitis was entirely independent of the operation because of the inability of any injected fluid, or any discharge from the cerebral abscess, to gain access to the base of the brain. This patient took daily from 120 to 150 centigrammes of quinine, and there is a possibility that that *may* have had something to do with the fatal issue.

These three cases show the tremendous difficulty of determining with exactness the part operative interference has in the production of death. But, to recapitulate, a careful review of the cases collected shows that, of one hundred unselected cases, twenty-six died; but that in twenty-three, there existed, at the time of operation, symptoms which of themselves endangered life, thus leaving for the operation *per se* a mortality of 3 per cent. This certainly should rob the operation of its terrors.

The introduction of three interesting cases at this point may show what extensive injury to the cranial bone may be recovered from.

In a case of syphilitic necrosis there was removed the frontal part of the frontal bone, the roof of both orbits, the cribriform plate of the ethmoid, parts of both superior maxillæ, the palate, and left greater wing of the sphenoid, without any untoward symptoms occurring.[1]

[1] Norton, Trans. Clin. Soc. Lond., 1880, xiii. 48.

McCutcheon[1] narrates a remarkable case in which he trephined five consecutive times.

The patient, an adult male, received a blow near the occipital protuberance. Six weeks of blindness supervened, which disappeared after trephining. Later, after the wound had all healed, symptoms of compression came on, which yielded to a second operation. Epilepsy appeared after a period of apparent cure. The third operation was successful. Atrocious headaches soon led to a fourth operation; while later, necrosed bone necessitated a fifth and last operation.

A man had his head caught between the timbers of a bridge and the boiler of a steamboat going at a rapid rate. The frontal bone was torn off at its lower border and raised up five centimetres. It could be raised and lowered like the lid of a box, the scalp and coronal suture acting like a hinge. The anterior lobes of the brain were elevated 1.5 centimetres. The bones of both orbits and upper part of the nose were crushed; one piece was driven into the brain, which was much lacerated. Seven fragments were removed, including the roof of both orbits, the septum between the eyes, and some of the nasal bones. A portion of the right temporal bone was crushed in, and there was a compound depressed fracture of the left parietal bone four centimetres long. Much lacerated cerebral substance was lost. Clotted blood and débris were removed, the frontal bone was adjusted, and drainage secured. Convalescence was marked by an immense discharge of serum and pus. Recovery was perfect as regards mental and physical condition, but there remained impairment of vision in the left eye, diplopia, impairment of hearing in the left ear, and a total loss of the sense of smell.[2]

The reluctance of the surgeon to open the cranium seems avidity as compared with his hesitation in piercing the dura mater. The protection afforded by antiseptic precautions has long since thrown down the barrier of other serous sacs, and now every day closed serous or synovial cavities are invaded for diseases not immediately endangering life. Not so with the sac surrounding the brain. The dura is not very vascular, nor does it easily take on ordinary inflammatory processes.

Vessels prone to dilate and allow transudation and exudation are just as readily made to contract by local or systemic treatment. The same readiness of the pia mater to become acutely inflamed, also renders it peculiarly sensitive to prophylactic or remedial measures.

Of the hundred cases which I have collected, the dura mater was opened in thirty-three. In twenty-three the dura was lacerated by the traumatism, of these nine, or 39 per cent., died. In ten cases the dura was purposely opened during the operation, and of these four, or 40 per cent., died.

This would seem to indicate that opening the dura mater led to fatal results in 39.3 per cent. of all cases, but when we pause to consider that opening of the dura during the traumatism is in most cases accompanied by laceration of the brain, hemorrhage, and often the introduction of foreign bodies, and that intentional exposure of the brain is seldom resorted to until dangerous inflammatory processes are already at work, we will find that this explorative

[1] New Orleans Med. and Surg. Journ., 1881, ix. 259.

[2] Palmer, Trans. Med. Assoc. of Wisconsin, 1880, xiv. 59.

procedure is, if not harmless, at least not fatal in 39.3 per cent. of cases.

Of the nine fatal cases in which the dura was opened traumatically, four died of extensive laceration of the brain and shock, two died from hemorrhage, one from the middle meningeal, one from the middle cerebral artery, and one died from opium. Of the four fatal cases in which the dura was intentionally opened, three already presented lesions of diffuse or circumscribed suppurative inflammation. In *one* case only, that of Sylvestrini, did the membranes, healthy when first opened, subsequently take on a fatal inflammation. Thus we see that of the thirteen fatal cases, in only one could death be traced to exposing the brain. This reduces the mortality of the operation to 7.6 per cent.

It is exceedingly exasperating that Sylvestrini neglects to state what dressing he employed or whether he did or did not conduct the operation with antiseptic precautions.

The surgeon who boldly trephines the skull, and then hesitatingly and after mature deliberation opens the dura, will generally draw back, lay down his instruments and refuse to go further when he reaches the brain. It is not because he considers it such a vital organ, for he knows full well that large areas of the brain are less essential to life than are the less noble organs, the heart, lungs, liver, and kidneys. Neither is it because he thinks it incapable of sustaining shock or taking on reparative processes, because he has seen it entirely recover from tremendous traumatisms, he has watched it granulate and cicatrize like any other wounded part. The cerebral cortex seems to be a sort of "dead line" inside the prison walls of conservative surgery, across which even the most daring are tempted or the most unwilling are dragged only by sure indications or desperate chances. Let us see how much foundation, in fact, there is for the sacredness in which the cerebrum is held. Leaving one side the older, but remarkable cases, such as the celebrated tamping-iron case of Drs. Harlow and Bigelow, we will cite more recent instances which demonstrate the toleration and reparative power of the brain.

A male, of thirty-one, received a punctured wound from a file which fell some distance, striking him at the posterior superior angle of the right parietal bone. Three days later, headache, delirium, and slight left hemiplegia came on. One month after the injury he was trephined, the dura was punctured and pus escaped in jets. He was discharged cured in two months. Nine months later convulsions and left hemiplegia returned. The old wound was reopened; this operation simply affording relief. Seven months later, headache came on, followed in a few days by convulsions. Speech and vision were impaired. The removal of a small piece of dead bone afforded no improvement. In four months the case came again under notice, with left hemiplegia most marked in the leg and double optic neuritis. Another small piece of dead bone was taken out.

The old trephine hole was enlarged, the dura punctured and pus escaped in jets. About 250 cc. escaped during the night. A director was passed five centimetres into the brain. After the pus was evacuated, the patient walked and moved the left arm and fingers freely, and speech was not so thick. One month after the operation, the headache returned and a convulsion occurred. At the same time the discharge from the wound increased. In fifteen days the wound healed, and in thirty days the patient was discharged cured, two months after the last operation, and sixteen months after the injury.[1]

Bullet weighing 2.5 grammes, entered five centimetres above eyebrows and one centimetre to the left of the median line. Of its own weight, probe went back its whole length toward the occiput. Free drainage was secured and carbolized oil was used as a dressing. The left optic nerve was swollen. On fourth day, when almost well, rigors and violent pain in the wound set in. Pulse 100; temperature 40.5° C. Unconsciousness, wild delirium, vomiting, and slight right facial paresis. Recovery without operation on seventy-fourth day.[2]

A bullet entering at point about four centimetres above the left eye a little to the left of the median line, pierced the first frontal convolution, traversed the brain backwards and a little outwards, and emerged from the upper part of the parietal lobule, where it lay slightly imbedded in the brain. The symptoms were not alarming. The course of the bullet was ascertained by careful probing, and the trephine was applied over the supposed site of the ball. After a short search it was found, and a drainage apparatus composed of horse-hair and catgut passed through the entire track of the ball. The operation was done with antiseptic precautions, and the wounds were dressed with iodoform. Recovery was uninterrupted and complete. The slight weakness of the right hand and loss of memory rapidly disappeared.[3]

The whole of the right parietal, parts of the right occipital, temporal, and left parietal bones being torn away with extensive laceration and loss of cerebral substance, the case was treated antiseptically without operation and recovered perfectly.[4]

A man was struck by the pilot of an engine and his head was cut open from the inner canthus of the left eye to the occiput. A furrow eight centimetres long was cut in the anterior lobe of the left hemisphere. Under cold applications he recovered.[5]

A boy of six years was stepped on by a horse. The left side of the head was crushed in, blood, bone, and brain escaping. Blood and pieces of brain exuded from left ear. It was estimated that sixty-two cc. of cerebral substance were lost. There were three compound fractures. There was a right hemiplegia which disappeared and an aphasia which improved.[6]

A boy of fourteen, was struck on the head by a stone weighing five kilogrammes. A large hematoma formed, which was opened; bone to the extent of 7.5 x 6.5 centimetres was removed, and thirty grammes of clear cerebral substance were saved. A carbolic dressing was used. Later, a large hernia cerebri formed and was cut off. Recovery took place without paralysis.[7]

A man of thirty-nine, fell fourteen metres, causing a slight wound in the right fronto-parietal region. Ten months later, convulsions and paralysis set in. A fissured fracture was found three centimetres long along the Rolandic line. The skull was trephined and the dura opened. Blood and cerebro-spinal fluid escaped, and the cortex was found disorganized over a considerable extent for a depth of many millimetres. Recovery with disappearance of the paralysis supervened.[8]

Adding to these traumatic cases the numerous instances in which immense hemorrhages, large areas of softening, stupendous and multiple abscess cavities, and rapidly growing neoplasms compress or usurp the place of parts of the brain without disturbing the vital functions and often without destroying life, we must conclude that the brain shows a remarkable tolerance of injury and a tremendous reparative power.

The chapter in cranio-cerebral topography which will be found of most utility for clinical and experimental purposes, is the part dealing with the relations borne by individual convolutions, not to the denuded skull, but to the external landmarks demonstrable on the living head. To this part special attention will be paid, the facts being chiefly drawn from Broca, Féré, and Turner.

To make all observations uniform, the head must have a constant position. This position is that which is assumed by a skull, without the inferior maxilla, resting on its alveolar processes and occipital bone. This is called the alveolo-condyloid plane, and forms the basis for all future measurements. A perpendicular from this line passing through the external auditory meatus, intersects the vertex at a point called the bregma. This is called the auriculo-bregmatic line. The most important landmark in the brain is the fissure of Rolando. Its upper extremity lies 4.5 centimetres behind the bregma (Broca, Féré, etc.). Its lower extremity falls about 0.5 centimetre behind the auriculo-bregmatic line, and a little above a line Féré draws through the head parallel to the basal plane, passing through the apex of the lambdoidal suture and the superciliary ridge of the frontal bone. (See figure.) This would bring the lower end of the fissure of Rolando about 6 centimetres above and a little behind the external auditory canal.

Having thus located the fissure of Rolando, enables us to map out the neighboring convolutions, which are to-day held to be of the greatest importance, as they are supposed to contain the psycho-motor centres of the opposite half of the head, body, and extremities.

The ascending parietal convolution will, of course, underlie the surface of the head just behind this region, while the ascending frontal is just in front.

The first or superior frontal convolution will be found commencing about 2·5 centimetres behind the bregma, and passing forward near the median line toward the orbit. The second frontal convolution will occupy a similar but more lateral position, while the third frontal convolution lies wholly in front of the auriculo-bregmatic line, and on a plane 5 centimetres above the external auditory meatus. Its folded or central part is about 2.5 centimetres in front of the auriculo-bregmatic line, or about 2 centimetres behind the external angular process of the frontal bone.

The tip of the sphenoidal lobe is 1 centimetre behind the external angular process of the frontal bone, hence at this point the fissure of Sylvius commences.

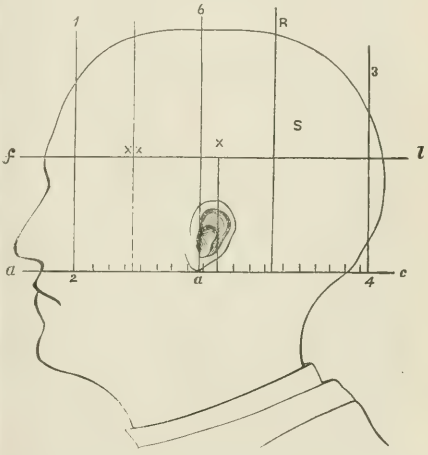
The middle or horizontal part of the fissure coincides pretty nearly with the squamo-parietal suture, and hence falls near the fronto-lambdoidal line. The termination of the fissure is in the lower posterior parietal region, and this would bring the supra-marginal convolution under the parietal eminence (Turner) and the angular gyrus below and a little behind the same.

The occipital fissure varies very little from the commencement of the lambdoidal suture, a point pretty easily made out in most heads. The relations of the fissure of Rolando to the antero-posterior diameter of the brain as determined by Féré are interesting. Its superior extremity is in the average 11.1 centimetres from the frontal extremity (range from 9.5–12.5 centimetres) and 4-9 centimetres from the occipital extremity.

The lower extremity of the fissure is 7.1 (6.4–8.2) centimetres from the frontal extremities, and 8.9 centimetres (7.2–10) from the occipital extremity of the brain.

With such data as are contained in the above paragraphs at our disposal, we can see the convolutions, so to speak, through the scalp, skull, and meninges.

FIG. 1.



Outline of head, reduced one-third, on which a modified system of Féré's lines is drawn. *AC*, alveolo-condyloid; *AB*, auriculo-bregmatic line; *FL*, fronto-lambdoidal line; 1, 2, frontal limit; 3, 4, occipital limit of the brain; *R*, posterior extremity of the fissure of Rolando; *X*, anterior extremity, same; *XX*, location of the middle fold of the third frontal convolution, a little below and in front of which lies the tip of the sphenoidal lobe; *S*, the posterior extremity of the fissure of Sylvius, and the intersection of the lines 3, 4, and *FL*, locates the occipital fissure.

Of cerebral localization as bearing on this subject, much might be, but very little need be, said. Neurologists are sure that there are certain regions of the brain which when irritated, compressed, or destroyed, give rise to perfectly unmistakable symptoms.

To recapitulate:

We have trephining, an operation proving fatal in only three per cent. of published cases:

Opening the dura mater, fatal in only 7.6 per cent. of published cases:

We have the brain, an organ tolerant of injury and ready to take on a reparative process:

We are possessed of a knowledge which enables us to tell when certain parts of the brain are diseased; and we also have anatomical data which tell us just where to pierce the envelopes of the brain to reach a certain definite part of its convexity. We have all the elements of safety and anatomical accuracy, why should cerebral surgery not advance with pulmonary, renal, intestinal, and ovarian surgery?

My allotted time and space are exhausted, and I close with a few practical remarks suggested by the subject in hand.

The substitution of the dental engine and a burr or drill cutting on the side for the ordinary trephine strikes me as advantageous. It has been used and advocated by Dorr[1] and Roberts.[2] Its advantage over the trephine is principally that with it you can cut away as much or little bone as you please, and make an opening of any shape you please. It is especially useful in trimming down the edge of overriding bone to allow the elevation of depressed fragments.

Let the operation always be done with antiseptic precautions. Try and secure only approximate coaptation of the flaps. Provide the freest possible drainage. Use cold antiseptic dressings, without much compression. Enjoin the strictest quiet in a posture facilitating drainage. Simple diet, and a slightly loose condition of the bowels. On the slightest rise of arterial tension or temperature, give jaborandi or aconite to the production of physiological effects. Quinine and alcohol should, I think, be given only in tonic doses. An anodyne is often indicated, and it is my advice never to use opium, or any of its preparations or derivatives. To ease pain, quiet delirium, or induce sleep, use the hydrate of chloral in small repeated doses (.60–1, every ten or fifteen minutes). Quinine and alcohol in large, and opium in *any* dose, aggravate intracranial inflammation when present, and, I think, may excite it.

These suggestions apply equally well, or with still greater force, to cases in which the dura mater or brain is accidentally or intentionally invaded.

A few words as to what I consider good indications for opening the skull.

An injury of the vault, however slight the marks of external violence, provided there be coma, aphasia, hemiplegia, or hemispasm of the lower part of the face, of the arm, or leg, or all three, constituting hemiepilepsy; whether accompanied or not by chills, fever, headache, and vomiting. General epileptic convulsions do not constitute so good indications for operation. Every case of compound fracture of the skull whether there be cerebral symptoms or not. Cases in which, after the lapse of months or years even, unmistakable cerebral symptoms follow an injury to the head. Atrocious and incurable headaches, particularly if localized, aphasia, monoplegias and monospasms, hemiplegic or hemiepileptic seizures or general epileptic attacks, if they have an aura pointing to a localized lesion. In addition to the bone, the dura mater should be opened; in all cases in which exploration with a hypodermic needle discloses the products of purulent inflammation or a great deal of fluid blood under it. In all cases in which a serious lesion of the brain is suspected, but cannot be otherwise proven.

In addition to the bone and dura mater the brain should be explored, delicately with a probe, in all penetrating wounds of its substance, punctured, lacerated, or gunshot. Its mass should be invaded, even when superficially intact, by a fine, blunt exploring needle, when the presence of foreign bodies or hidden collections of pus are suspected, and, for the extraction or evacuation of such, larger openings should be made with a dull instrument.

Finally, accessible neoplasms of the brain, which have resisted medicinal treatment, and which continue to grow and threaten life, should be removed for the reason that they are generally single, seldom have secondary deposits, are surrounded by an inflammatory zone of demarcation, and *always* kill by pressure.

SUCCESSFUL RESECTION IN PSEUDARTHROSIS OF HUMERUS.

BY A. C. GIRARD, M.D.,
CAPTAIN AND ASSISTANT SURGEON, U. S. A.

THE result of unusual operations ought to be reported to the profession, whether successful or not. These reports are the data on which our statisticians base their papers, and the fear of accusation of self-laudation should not deter physicians from publishing successful cases, if they improve statistics, and thereby are an encouragement for surgical interference to restore full usefulness to an otherwise maimed limb.

In this spirit, the following case is submitted to the profession, with a skeleton history, omitting anything that does not pertain to the surgical treatment, but recording what has given the writer much concern to bring the result to a favorable issue.

In June, 1883, the patient, F. R. T., sustained a simple fracture in the upper third of the humerus. He was admitted to the hospital, and treated, during my temporary absence in the East, with felt splint, apparently making a good recovery; but eight months afterwards, having during all that time eluded an examination, he appeared before me, because his term of enlistment was soon to expire, and he desired reënlistment, and feared he could not pass the examination which would then be made. I found a pronounced pseudarthrosis about the indention of the deltoid muscle; an attempt to raise the arm first lifting the upper fragment, and the remainder of the arm after the limit of mobility had been reached. Even in this condition there was considerable power, and no soreness. T. being a married soldier, and of somewhat intemperate habits, I came to the conclusion that, being too soon discharged from the hospital, anxious to help his wife, and perhaps subjected to occasional falls, he had prevented ossification by the imperceptible strains brought to bear on the seat of fracture.

Time being of paramount importance, the question

of exciting ossification by the usual means had to be disposed of in the negative, and T. nursed himself up to the ordeal of an operation which was appointed for January 14, 1884. A. A. Surgeon J. C. Martin, U. S. A., ably assisted.

Chloroform being administered, and Esmarch's bandage applied, a longitudinal incision, about five inches long, was made in the space between the insertion of the deltoid and median vein. A large callus was reached, and incised likewise, to find the exact location of the pseudarthrosis; a circular incision divided this at the juncture of the fragments, but this incision had to be carried through skin and part of the deltoid to obtain room enough. Considerable difficulty was experienced in dividing the remote parts of the arthrosis, owing to the close proximity of the brachial artery; but finally the bones were everted, and their face (after scraping back about one-quarter of an inch of periosteum) sawed off the same distance. The bones then came almost into exact coaptation, and holes were drilled into them for two strong silver-wire sutures, which were twisted and cut off long enough to facilitate removal. Esmarch's bandage being removed, copious venous hemorrhage ensued, which was stopped partly by elevation and partly by compression in the wound and over the axillary artery to lessen the blood supply.

During the latter part of the removal of bone, my assistant being busy keeping the soft parts retracted, and the chloroform entrusted to a convalescent, I happened to look up, and found that the patient had ceased to breathe. Being prepared for such mishaps, I dropped his arm, seized his legs, and swung them over my shoulder, meanwhile ordering amyl to be applied to the nostrils, artificial respiration established, and vigorous slapping over the region of the heart to excite its action. The impediment soon passed off. I mention this in support of my advocacy, in other papers, of the safety of chloroform, if properly handled.

The parts were then brought together with interrupted sutures, dressed with a Lister dressing, and put on a wooden splint. Considerable oozing took place for two days, for which the surroundings of the wound were packed with marine lint.

On January 22, eight days after the operation, the wound being covered by boracic ointment, spread over lint, a plaster-of-Paris bandage was applied, covering the arm from the shoulder to midway between elbow and wrist, and encircling chest and opposite shoulder. The arm part of the splint was strengthened by perforated tin strips between the layers of bandage. A large fenestra was then cut to dress the wound.

In two days, owing to the lack of support of the splint, the lips of the wound receded, and gaped widely open; they were brought and held together with button sutures and silver wire, which were removed in a few days, and found to have accomplished their task successfully.

From that time, the case progressed without drawback. The suppuration was moderate. One of the silver wires holding the bones appearing loose, it was removed with the edge of the bone, about the size of a millet-seed. The other wire, being shorter, had slipped under the tissues, and was removed six weeks after the operation, as it happened to appear in sight. As the tissues receded, and the plaster splint caused painful pressure on the different bony eminences, the fenestræ were cut and padded.

On the fifty-sixth day after the operation, the plaster splint was removed, when the operation found to have been entirely successful, the arm being straight and solid. Neither shoulder nor elbow-joint seemed to have suffered from the enforced inactivity, and to-day, March 22, I found the arm freely movable, and the plan of fracture only discernible by the callus.

I made this history longer than the gravity of the case seems to warrant. The works on surgery, however, being very incomplete in advising how the different phases of such an operation should be met, especially on advanced notions, I believe my experience in this case may prove useful as a clinical guide to operators who, like me, encounter this operation for the first time in their practice.

In conclusion, I might state that the patient's temperature was practically normal after the first reaction. A solution of bichloride of mercury was used for all purposes of ablution, and gave me great satisfaction in this as well as in other surgical cases, since I have discarded the carbolates in consequence of the researches of Dr. Sternberg, U. S. A., on the relative value of antiseptics.

FORT KEOGH, M. T.

MEDICAL PROGRESS.

ON THE DIGESTION OF RAW AND OF BOILED MILK.—DR. N. A. RANDOLPH, at a recent meeting of the Academy of Natural Sciences, of Philadelphia, referred to certain profound changes produced in milk by boiling. In this operation the casein is not coagulated, but there is an evolution of sulphuretted hydrogen (Schreiner), a diminution in the gaseous constituents of the fluid and a change in the amount of ozone present.

The most striking difference between raw and boiled milk lay in the respective responses to rennet, acids and alkalies.

At the body-temperature the firm coagulation of raw milk occurred almost immediately upon the addition of a neutral rennet solution, whereas boiled milk, under the same conditions, did not clot for a far longer period, and the coagula were not firm. On the other hand, dilute or strong acids were tenfold as active upon boiled as upon raw milk. Some time after making these experiments Dr. Randolph found that, so far as acids and rennet were concerned, similar results had been obtained by Schreiner (*Chem. Centralbl.*, III. Folge, IX. Jahrg.), and he desired to present his observations in these particulars simply as confirmatory of that observer.

Upon the addition of dilute alkalies to boiled milk, the rise of cream was much more rapid and complete than in raw milk under the same conditions.

Artificial digestions showed that milk was more readily digested when raw than when boiled. This was further confirmed by a comparative examination and weighing (in over fifty cases, and in which he was aided by Dr. Roussel) of the contents of the stomach

after raw and boiled milk had been, in different individuals, undergoing actual gastric digestion. In these cases the residue found in the stomachs of those persons receiving boiled milk was greater than the similar residue found in the stomachs where raw milk had been undergoing digestion for the same length of time.

These results are confirmatory of those of Jessen, who made several observations on one healthy individual. In the studies of Drs. Randolph and Roussel, the sources of error arising from individual peculiarities were eliminated, inasmuch as the experiments were conducted upon eight healthy men.

Treatment of Leucorrhœa.—Dr. Fruhauf uses the following method in cases in which the ordinary treatment fails: He commences by disinfecting the vagina by injecting into it a solution containing 1 to 100 of carbolic acid and 4 to 100 of boracic acid. Then, with a speculum, he introduces three or four oakum tampons, each as large as a walnut and containing grs. iss to iij of iodoform, and each having a string attached for ready removal. These are left *in situ* for two or three days. If there is an ulcer of the cervix, he cauterizes it with a solution containing equal parts of acetic acid and distilled water. Of course, in some cases general treatment must be resorted to. For this, Fruhauf prefers the phosphate and lactate of iron.—*Journ. de Méd. de Paris*, March 8, 1884.

Litholapaxy.—Surgeon P. J. Freyer, of the Bengal Medical Service, reports a series of 57 cases of litholapaxy performed in 1883. During the year, 107 cases of stone came under his observation. Of these, 6 were cases of urethral calculus, all of which were successfully operated on by urethrotomy. There were 40 cases in male children or boys under the age of fifteen; these were all operated on by lithotomy, with 1 death. In the remaining 61 cases, all of which occurred in adult males, with the exception of 3 instances, in female children, litholapaxy was attempted; but, for various reasons, in 4 of the cases the operation could not be performed. Of the 57 cases, 2 were fatal; 1 from peritonitis, evidently by extension of inflammation from the neck of the bladder; the other died of pyæmia, the result of cystitis. Freyer suggests a new method of diagnosis by means of the aspirator. In one case a most careful search was made by means of sounds of various kinds, but no calculus could be detected till the aspirator was employed, when a distinct click was at once felt during exhaustion of the water from the bladder, and due to the calculus being carried with force against the eye of the canula by the outward stream. He has now performed 79 litholapaxies, with only 3 deaths.—*Indian Medical Gazette*, March, 1884.

Splenectomy.—Mr. Knowsley Thornton removed a spleen, at the Samaritan Hospital, on April 22, by the median abdominal section. All its lower part was hollowed out into a multilocular cystic cavity, and it weighed two pounds. The patient, a single girl aged nineteen, had been known to have a tumor for two years, but latterly it had grown fast, and given much pain. During the tying of the pedicle, the shock was very severe, but she revived directly the tumor was cut away and the drag taken off the pedicle. She is progressing satisfactorily. The specimen will, we understand, be shown and further progress reported at the Pathological Society.—*Lancet*, April 26, 1884.

Benzoate of Soda in Infantile Diarrhœa.—Dr. R. Guaita (*Rivista Italiana di Terap. e Igiene*, Gennaio, 1884) thinks the summer diarrhœa of infants is for the most part a zymotic disease, and due principally to a special ferment (microbe), which either comes from without, or is developed during the process of digestion from certain kinds of food. It occurred to him, therefore, that benzoate of soda, recommended by Kapuscinsky and Zilewicz, would prove valuable in these cases, being antifermentative; it may be administered alone, or in combination with bismuth.

This treatment was tried in 53 cases, the children being from six months to two years old. In 35 cases the affection had lasted from 24 to 30 hours, in the remaining 18 from 6 to 14 days; in the 35 cases, the cure was complete in from 4 to 8 days; in the 18, the average time was 21 days. The treatment is preceded by an efficacious purge—calomel or jalap; this having acted, the soda treatment is commenced.—*Gazz. degli Ospitali*, March 30, 1884.

Pistol-ball in the Brain.—In October, 1882, Dr. Sonlonwiae saw a boy, five years of age, who had received a pistol-ball in the head. Its point of entrance corresponded to the third convolution of the left anterior frontal lobe. The boy was unconscious for forty-eight hours. At the same time a hernia cerebri appeared. For five days there was complete aphasia, but this gradually disappeared. Paralysis of the left arm then appeared, which lasted for fifteen months. There has been no encephalitis at any time, and the boy is now, to all appearances, well.—*Gazz. degli Ospitali*, March 30, 1884.

Ligature of the Subclavian and Common Carotid for Innominate Aneurism.—Dr. Julius Rosenstern reports a successful case of this operation, performed on a woman æt. 42 years. The aneurism dated for two years. The patient was out of bed in about five weeks. At present there is hardly a trace of the tumor, though the pulsation has not yet entirely disappeared.—*Pacific Med. and Surg. Journ.*, March, 1884.

Vaginal Extirpation of the Uterus.—Professor Peruzzi performed this operation on April 8, in the hospital at Lugo. The patient was thirty-four years old, and had cancer of the sub-vaginal cervix uteri with supra-vaginal infiltration, but without infiltration of the uterine body. Billroth's operation was performed with antiseptic precautions. On April 18, the patient was without fever and was rapidly improving.—*Gazz. degli Ospitali*, May 7, 1884.

Nephrorrhaphy. — Prof. Andrea Ceccherelli performed this operation in February, at the Surgical Clinic in Parma, for painful movable kidney. Kahn's method was employed. There were no untoward symptoms, and after thirty-six hours there was no fever.—*Gazz. Medica di Torino*, March 25, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, JUNE 21, 1884.

SUPRAPUBIC LITHOTOMY.

THE operation of suprapubic lithotomy seems to be undergoing a revival of interest at present. So short a time as ten years ago, it was rarely spoken of and hardly ever performed. Now it has ardent advocates in this country and tolerant critics in Great Britain, while in France it is being most enthusiastically championed, and in Germany it has just been put as the alternative for rapid lithotrity. In a recent paper in the *Wiener med. Wochenschrift*, (1884, Nos. 3–11), PROF. V. DITTEL discusses "The Relation of Litholapaxy to Suprapubic Lithotomy," and indicates a manifest preference for the latter method of cutting for stone, in cases in which crushing is not applicable. His article is long and contains a report of a number of cases operated upon by each method. In regard to the merits of Bigelow's operation, Dittel is in accord with most modern surgeons. In regard to the cutting operation, he is in advance of the majority. He states the often repeated arguments, founded on anatomical considerations, in favor of suprapubic lithotomy, and gives a number of indications for its performance in preference to litholapaxy. The objections to it, he maintains, would disappear if it were more used. He thinks it would bring lithotomy to perfection, if it were possible to conduct the after-progress of the wound as safely as can nowadays be done in the case of other wounds of the periphery. He further seems to think that such an end is not unattainable, for he urges it as a duty that every surgeon, whose position and reputation bring him a large clientèle, shall cultivate this method, so that its success may overcome the objections often urged against it.

In occupying this position, Dittel agrees with those surgeons who think that Bigelow's method of lithotrity is likely to eliminate from stone operations all the calculi which have heretofore proved the most amenable to perineal lithotomy, and leave those in which this has proved very hazardous; in other words, the stones which are best suited for removal through the hypogastrium. Such being the case, it seems timely to make some remarks on the claims and present status of the suprapubic method.

It is claimed for this method that it is scientific, exact, free from a number of hazards attaching to perineal operations, easy of execution, and satisfactory in its results. These claims, however, are not universally admitted. On the contrary, the prevailing opinion and practice still treat this method as if it were more hazardous than others. Yet it is to be observed that those who have most carefully studied the subject, have an enthusiasm for suprapubic lithotomy which appears to be in a definite ratio to their familiarity with its actual history and achievements, while those who, in our day, oppose it, usually indicate by their arguments, a bias against it, and an imperfect acquaintance with what has been done for it by act and pen, especially during the past ten years. Before that time the operation may be said to have fallen almost into oblivion. It is true that in Germany Günther had, in 1851, published a valuable monograph, containing reports of 260 cases, in which he refuted many of the objections urged against it, and recommended it for general adoption. But the light his labors shed upon its merits, which had done much to save it from being thought as ill of among his countrymen as elsewhere, was fading even there, while it never penetrated to France, England, or America until it had almost gone out at home.

Twenty-five years after Günther's effort, Dr. Dulles published in the *American Journal of the Medical Sciences*, for July, 1875, as the first of a series of papers on this subject, an elaborate article in favor of the general adoption of suprapubic lithotomy, founded upon a number of cases so large (four hundred and seventy-eight) that we find Prof. Dittel, in the article before us, casting some doubt upon their credibility. Dr. Dulles argued that the dangers of the suprapubic operation had been much overrated, and that the fears of it were founded upon common belief, not on facts. He emphasized the disadvantages under which it had labored, and developed the remarkable conclusion that its results, in spite of these disadvantages, were almost as good as those of lateral lithotomy for all stones above an ounce in weight, and progressively better for all those weighing more than two ounces. The operation he declared to be simple, easy of execution, and safe, if applied to cases in which any method could be considered to be safe.

In the same year Prof. Dittel did his first operation of this sort, and expressed considerable enthusiasm over the result. A number of American operations also followed, with such success as to make the operators hearty endorsers of the method. In 1879 Dr. Flury published, in Tübingen, a monograph in which the statistical work of Günther was taken up and carried on, from 1850 to the former date. In the same year Prof. Van Goudoever, of Utrecht, advocated at the International Medical Congress at Amsterdam, the more general employment of this method, reporting fourteen successful cases. In 1880, Prof. Petersen, of Kiel, suggested, as an improvement in the *technique*, to raise the bladder out of the pelvis by distending a colpeurynter placed in the rectum, and reported some successful operations done in this way. The next year Langenbuch, of Berlin, proposed a curious method of doing the operation *en deux temps*, and Anger presented at the International Medical Congress at London, a set of thermo-cautery instruments, which he thought would eliminate some of its dangers. The same year Dr. Lange, of New York, did two suprapubic operations in which he secured union of the wounds by the first intention. About this time M. Charles Monod, of Paris, took the subject up, and, in a report to the Surgical Society of Paris, declared that this method is relatively easy of execution, that the dreaded wounding of the peritoneum can be almost infallibly avoided, and that the operation is too much neglected by our contemporaries. Within the last ten years a number of surgeons in Germany, Austria, and France, have been practising and advocating it, among them Ultzmann, Albert, Dittel, Petersen, Guyon, Perrier, and Bois, while its most recent literature includes a valuable thesis by M. Ch. Broussin, published in Paris, in 1882, and a monograph of more than 250 pages, published in 1883, by E. Bouley.

From this it may be seen, as stated above, that the operation of suprapubic lithotomy is having a decided revival at the present time. In Europe this revival has reached a large number of surgeons on the Continent, although it does not seem to make much headway in England, where a number of authors still rest their opinions of it on the imperfect table of Prof. Humphrey, containing 103 cases and published in the same year that Günther published his 260, being apparently ignorant of other work of the same sort, while at the recent meeting of the American Surgical Association, the discussion on a case reported by Dr. Tremaine disclosed an equal lack of information as to what has been going on in regard to it, in this country and in Europe, during the past ten years. The only one of the Fellows who seemed to be aware of the increase of interest in this subject made a prediction which was the more astonishing from the fact that his hearers were utterly unprepared for it, namely, that in ten years this would be the operation in common use. This prediction may be regarded as somewhat sanguine, but it seems at least to be more in keeping with the reasonable prospects of suprapubic lithotomy than the adverse opinions which have come down from previous generations. It would, indeed, appear as if Prof. Dittel had good reason for intimating, in the article we have referred to, that the future of stone operations belongs to litholapaxy and suprapubic lithotomy.

COLLECTIVE INVESTIGATION OF DISEASE VERSUS THE INFECTIOUS NATURE OF PNEUMONIA.

IN our issue for May 24 we discussed some views on the origin and nature of pneumonia, elicited at the session of the recent Congress of German Physicians, which tended to show the infectious nature of the disease. Moreover, we find that they involve statements which are at variance with others contained in the preliminary report on acute pneumonia of the British Collective Investigation Committee, and therefore, call for further consideration.

Jürgensen, in the paper referred to, says that three-fifths of all cases of pneumonia occur between the 1st and 14th years; and of the remaining two-fifths, the number of cases after 45 is double that between 14 and 44; in other words, two-fifteenths of all cases occur between 14 and 44, and four-fifteenths after 44—the object being to show that the older notion that acute pneumonia occurs during the period in life of greatest vigor, is erroneous.

From the report of the British Committee, we learn that 269 cases occurred between 10 and 60 years of age, of which 195, or about two-thirds, were between 10 and 40, the distribution in decades being, 70 between 10 and 20; 70 between 20 and 30; and 45 between 30 and 40; this leaves 74, or one-third, between 40 and 60. Now, although the periods of time comprehended are not identical, they are sufficiently so to permit the comparison with Jürgensen's statistics, which exhibits a marked discrepancy, the observations of the British Committee showing that acute pneumonia is more prevalent between 10 and 40. As Jürgensen does not furnish the data on which his results are founded, and those of the British Committee are based upon a system entirely independent of any conclusions to be proved therefrom, we are inclined to attach the greater weight to the latter.

Again, Jürgensen states that only 4 per cent. of all cases originate in cold, the remainder being doubtful or independent; also that in Tübingen, when the rainfall exceeded the mean, the cases were fewer than under opposite circumstances; and Edlefsen makes the same statement with regard to Kiel. The British Committee inform us that more than one-half the total number of cases arose when the weather was damp or wet, and even a larger number when it was

cold, the combination of cold and wet being particularly favorable to the development of the disease.

In the matter of the sanitary surroundings of the cases there is less discrepancy, these being reported by the British Committee "indifferent" or "bad" in 170 out of 342 cases, and doubtful in 8; and of 341 districts in which pneumonia was prevalent, 168 were "indifferent" or "bad," and 173 good.

Again, according to the British Committee's report, premonitory symptoms were present in about 270 cases, absent in 80; *rigor occurred at the onset in 241* cases, and was absent in but 39; catarrhal symptoms preceded the attack in 40, and cough in 29. The frequent occurrence of rigor is significant, compared with the statement of Jürgensen, with which it is not in accord.

In the matter of communicability, on the other hand—in regard to which Jürgensen furnishes no direct data—the British Committee refer to a striking instance in which a husband is supposed to have taken the infection from his wife, another of a wife from a husband, one of a child from its companion, and another in which four members of a family were attacked in succession. In all these instances the sanitary surroundings were good. Three epidemics of pneumonia were also reported. No facts are furnished in the British report on the subject of Friedlander's pneumonia-coccus, the observations having been made prior to its discovery.

As to treatment, the British reports show the greatest diversity, but tend to prove that the disease runs a definite course, let the treatment be what it may. More unanimous, however, is the verdict in favor of alcohol and cardiac stimulants, than toward any other line of treatment, the tendency to death being mainly from cardiac failure; and in this respect the observations of the German and English physicians are in entire accord. Quinine, digitalis, and aconite were much used, but the extreme antipyretic measure of the German school —the application of the cold bath, was not employed in a single case by the English. Counter-irritants, poultices, blisters, and leeching were frequently used, but only *one case of venesection is reported;* "a solitary instance," says the author of the British report, "of the one measure which, a generation ago, would have been adopted in every case without hesitation." Of the 350 cases, 282 recovered, and 68, or 19.4 per cent., died; of males, 18.7 per cent.; and of females, 20.8 per cent. Would this mortality not have been less had venesection been more frequently performed?

As might be expected from the above statements, the conclusion of the British Committee was that the evidence before them was insufficient to support the doctrine that pneumonia is a specific fever, whose chief local manifestation is in the lung.

From the above, too, some idea may be obtained of the value of the collective investigation of disease, although the report on pneumonia is much less striking in this respect than some others, and we are glad to see that the Medical Society of the State of Pennsylvania has taken steps which are calculated to test its value in this country.

EPILEPSY AND PREGNANCY.

THE relative effects of epilepsy and pregnancy have been occasional subjects of professional discussion; and while there has been general agreement that the pregnancy is not, as a rule, injuriously affected by the epilepsy, there has been not a little difference of opinion as to the effect of the former upon the latter.

Having recently had charge of an epileptic who became pregnant, and was delivered at full term of an apparently healthy, well-developed child, we watched the case with great interest. Her epileptic attacks were not modified as to frequency, or as to severity, either during pregnancy, or after labor.

In a recent monograph by DR. BÉRAUD, upon epilepsy in its relations with pregnancy and labor, the subject is quite well studied, the author having analyzed forty-six cases. One of his conclusions is that while in some cases of epilepsy, pregnancy is without any effect upon the disease, in others it has an injurious effect; in a number slightly greater than these two classes, its influence is beneficial. But in cases favorably affected, the modification is only temporary, and, as a rule, it ceases with gestation.

THE S. D. GROSS PROFESSORSHIP OF PATHOLOGICAL ANATOMY.

WE call attention to the appeal, in another column, for establishing this memorial chair. Such a movement cannot fail to receive the cordial endorsement, and the earnest help of the profession of the entire country. Not only this, but physicians should endeavor to influence the liberal-minded and the generous-hearted among the laity in its favor. The fame of Dr. Gross gave honor to the American name in all enlightened countries, and his memory should be perpetuated in the mode proposed by a common contribution from the American people. It should not, therefore, be left to his own profession alone to erect this suitable monument to his memory, but the coöperation of the public should be obtained. By acting thus in concert, and by acting promptly, the work may be accomplished within a brief period.

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

ELSEWHERE we publish a brief account of the arrangements which have been made for the Copenhagen Congress, to be held in August next. The programme is very full, and the subjects announced

for consideration, over two hundred in number, are diversified in scope and extremely attractive in character. We regret to note that no American is among the names announced for addresses in the General Sessions; for this, however, the Organizing Committee is not responsible, since neither of the gentlemen from this country whom they invited felt able to accept the honor.

The Congress will receive a formal invitation from a committee of the American Medical Association to hold its next session in Washington, in 1887, and we know that we represent the sentiment of the profession in saying that, if it is accepted, our foreign colleagues may feel assured of a most cordial reception on this side of the Atlantic, and that every effort will be made to secure a pleasant and profitable meeting in the Capital of the United States.

SOCIETY PROCEEDINGS.

MASSACHUSETTS MEDICAL SOCIETY.

One Hundred and Third Anniversary, held at Boston, June 10 and 11, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 10TH—FIRST DAY.

IN the morning the Fellows of the Society were invited to visit the Massachusetts General, City, Children's and Lying-in Hospitals, where members of the medical and surgical staffs were in attendance.

Several interesting operations were performed, among them a case of litholapaxy, by Dr. H. J. Bigelow, and an operation for the radical cure of hernia, by Dr. J. C. Warren, at the Massachusetts General, and ligature of the femoral for a large aneurism of the calf of the leg, by Dr. Charles D. Homans, at the City Hospital.

At noon the Society met at the new building of the Harvard Medical School, to listen to a communication by DR. H. P. BOWDITCH, on

METHODS OF INSTRUCTION AND RESEARCH IN PHYSIOLOGY, WITH DEMONSTRATIONS.

Dr. Bowditch, in welcoming the Society, said: "Mr. President and Gentlemen: The Massachusetts Medical Society has been invited to assemble to-day in the lecture-rooms of the Harvard Medical School, in order that the members may have an opportunity to examine for themselves the methods here employed in giving instruction in anatomy and physiology, and to inspect the appliances used for original investigations in these departments."

The arrangements of the physiological laboratories and lecture-rooms were then explained, and a large number of original experiments and sets of apparatus in working order were exhibited and explained. Dr. Bowditch was assisted by Drs. J. S. Warren, Garland, Putnam, and Ellis.

The effect of irritation of the vagus nerve on the blood-pressure of the dog, vaso-motor nerves of the cat and frog, studied by means of the plethynmograph; effect of temperature on the rate of heart-beat of frog; the force of ciliary motion, as illustrated by the power of a piece of ciliated mucous membrane of the frog to carry a load up an inclined plane; subjective complementary motion produced by a revolving spiral figure, and the reaction time studied by means of the pendulum myograph were shown. The animals used in these experiments were under the influence of large doses of ether or morphia.

DR. ERNST exhibited his

APPARATUS FOR THE CULTIVATION OF THE TUBERCLE BACILLUS,

together with specimens obtained by cultivation and inoculation, the fourth generation from the primary culture being shown.

DR. THOMAS DWIGHT then received the Society in the anatomical lecture-room, and spoke on

MODERN METHODS IN ANATOMY.

He referred to the duty that the holder of a professorship in a university owes to the profession or the community, and of their right to expect from him an account of his views and plans of instruction. He spoke of the great anatomical museums of the old world and the names of the great anatomists that are associated with them. Connected with the Medical School is the Warren Museum, founded by the late Dr. John C. Warren, professor of anatomy and surgery. This museum was greatly enlarged and improved by the many years of patient labor of the late Dr. J. B. S. Jackson, but though it contains a considerable collection of normal anatomy, it is essentially a pathological museum.

The science of anatomy still has a future, though one sometimes hears the contrary opinion expressed. It is true that the component parts of man are still the same as formerly, and that they have been fairly well described, but the methods of study are constantly undergoing changes for the better, the relations of embryology and comparative anatomy to normal anatomy are better understood, and the advance of topographical anatomy marks an era in the science. The method of study and demonstration by means of frozen sections is a great aid to other methods, though it can of course never take their place.

It is only within a few years that the position of the stomach has been correctly described, that is to say, with its lesser curvature nearly vertical instead of horizontal; the idea of the liver has also been changed by the researches of His, who describes it as it exists in the body with a posterior surface, and to-day the position of the ovaries is still a subject of dispute. The relations of the pharynx, mouth, and œsophagus are shown by Braune to be materially different from those pictured in the older, and even in some of the best recent anatomies.

Dr. Dwight then showed a series of thin sections of bones, illustrating their structure, and various frozen sections of different parts of the body. A series of corrosion preparations, including colored ones of wax and resin made by himself according to Rüdinger's directions, and others in fusible metal prepared by Dr. Mixter, assistant in anatomy, were shown. These give a clear idea of the extent and distribution of the vascular system of different organs as well as the shape and capacity of cavities, such as the air-cavities of the head,

the ear, etc. The wax and resin preparations possess the advantage that the different systems, where two or more are shown in the same specimen, can be made of different colors, while the fusible metal is much less brittle, is not in danger from changes in temperature, and the injection can be made even finer than with wax. (The alloy used is that known as Wood's fusible metal: Seven parts of bismuth, four parts of lead, two parts of tin, one part of cadmium. The tissues are destroyed by a saturated solution of caustic potash).

At three o'clock the Society met in Huntington Hall to listen to a paper by DR. GEORGE W. GAY, of Boston, on

THE PLASTER POSTERIOR SPLINT IN THE TREATMENT OF FRACTURES OF THE LEG, WITH ITS PRACTICAL APPLICATION.

He exhibited several patients wearing the splint, and applied one before the Society. The method is as follows: The leg is first enveloped in cotton batting, and a piece of crinoline is cut so as to envelop the limb from the toes to above the knee. The edges of this piece should be about an inch apart, along the front of the leg. With this as a pattern, six or seven similar pieces are cut, rubbed with plaster mixed with warm water and placed around the limb. A roller bandage is applied while the plaster is setting, and is then removed. This splint is especially adapted to simple fractures of the leg without extensive injury to the soft parts, and where there is not great tendency to displacement. As a fenestrated dressing it may also be used in certain cases of compound fracture. It is of especial value in children. Its advantages are that it holds the fragments firmly in position, cannot strangulate the limb, allows of easy inspection, and is very comfortable. This splint has given great satisfaction at the Boston City Hospital, where it has been in constant use for some years.

The reader spoke of the difficulties in the treatment of Pott's fracture, which gives more trouble than almost any other form of fracture of the leg. The patient should be confined for a long time, not less than three months in case of a patient of one hundred and fifty pounds, and longer for heavier persons.

This dressing is of great service in cases of ununited fractures of the leg, the patient being allowed to go about on crutches. Enough irritation at the seat of fracture seems to be produced to cause union in the majority of cases.

AN ADJOURNED MEETING

of the Society was held at four o'clock. At a previous meeting it had been held that the Society had no power to institute by-laws, the councillors alone having that power. After an animated and somewhat heated debate this ruling was not sustained by the Society, and on motion of DR. H. I. BOWDITCH the meeting voted so to amend the by-laws as to

ADMIT WOMEN TO THE SOCIETY

on the same terms as men. The motion was carried by a vote of about two to one. A concurrent vote of the councillors being necessary to render the measure operative, a committee was appointed to bring the matter before that body in the evening.

A STATED MEETING OF THE COUNCILLORS

was held at 7.30 o'clock. The action of the Society as regards the amendment of the by-laws was concurred in by a vote of sixty-three to forty-seven. This finally decided the question that has so long agitated the Society.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Charles D. Homans, M.D., of Boston.
Vice-President.—A. C. Deane, M.D., of Greenfield.
Treasurer.—Frank W. Draper, M.D., of Boston.
Corresponding Secretary.—Charles W. Swan, M.D., of Boston.
Recording Secretary.—Francis W. Goss, M.D., of Roxbury.
Librarian.—E. H. Brigham, M.D., of Boston.
Orator.—Frank K. Paddock, M.D., of Pittsfield.
Annual Chairman.—Robert Amory, M.D., of Boston.

WEDNESDAY, JUNE 11TH—SECOND DAY.

The 103d annual meeting was called to order at 9 o'clock, THE PRESIDENT, DR. ALFRED HOSMER, of Watertown, in the chair.

After the routine business had been transacted, the following medical papers and communications were presented.

F. NICKERSON, M.D., of Lowell, read a paper entitled

A CASE OF CHYLOUS DEPOSIT IN THE ABDOMEN.

The patient, a previously healthy, hard-working man of forty-five, was attacked with sudden pain followed by swelling of the abdomen. When seen the next day, a well-defined tumor was discovered in the lower part of the abdomen, and two quarts of a milky fluid were drawn off by aspiration. This fluid was found to contain a large quantity of albumen, fat soluble in ether, a little cholesterine, molecular granules, and lymph corpuscles—no urea was found. At varying intervals, during more than two years, similar attacks occurred, sometimes accompanied by vomiting of a milky fluid, and once, according to the statement of the patient, a quantity of the same was passed by the rectum. The tumor was aspirated several times, always with the same result, though the quantity of fluid became less. It is now eighteen months since the last attack, and the patient seems to have fully recovered.

In searching for the probable cause of the tumor, the reader considered all the forms of chyle- or lymph-containing growths, and concluded that it must be due to a rupture of some large lymph duct. Noteworthy features of the case are its sudden appearance, its long duration, the continued loss of lymph, and the final recovery of the patient.

L. HUNTRESS, M.D., of Lowell, read a paper entitled

THE PITCH OF THE PERCUSSION SOUND.

The reader spoke of the importance of this sign in physical diagnosis and the varying statements that are made concerning it in works by the well-known writers on the subject. A careful examination had been made of over two hundred healthy persons by the reader, to determine the normal condition in this respect. It is found that different parts of the same healthy chest may give a percussion note of varying pitch, and that the two

sides, in a large proportion of cases, present a marked difference. Hence, difference in pitch does not necessarily mean disease. Much confusion also exists as to the pitch of the tympanitic percussion note. This is probably due to the fact that the pitch depends on the volume of air in the cavity, the tension of the walls, and whether or not there is a communication between the cavity and the open air, as through an eroded bronchus.

J. F. A. Adams, M.D., of Pittsfield, read a paper entitled

SANITARY FOREST CULTURE.

The reader spoke of the three-fold influence of forests: 1. On the flow of streams. 2. The moderation of the climate. 3. The prevention of malaria. Streams are found to be much more regular in their flow when they arise in forests, these acting as reservoirs for the storage of moisture and preventing the too rapid melting of snows, and hence, heavy spring freshets. Many rivers are now subject to variations from overwhelming floods to an almost dry bed, that formerly, before the forests of their water-sheds were cut away, were much more regular in their flow.

It is a well-recognized fact that in many places malaria now exists, where before the removal of the forests it was unknown; and also, that the planting of trees in malarial districts may have a most beneficial effect. States should pass laws protecting forests, taking control of them if necessary; should encourage a knowledge of forestry by the establishment of schools, and plant large tracts of what are now waste lands, with timber.

J. Seaverns, M.D., of Roxbury, read a paper entitled

WEIGHT AS AN INDICATION OF THE CHARACTER OF RISKS FOR LIFE INSURANCE.

The reader discussed the value of the present standard of weight as compared to height, as generally accepted by life insurance companies, and from a careful study of a large number of recorded deaths, concludes that the margin of twenty per cent. above or below this standard, which is the customary allowance, is not correct. The limit should be fifteen per cent. for those under normal standard, while it may be increased to twenty-five for those above.

THE ANNUAL DISCOURSE

was delivered by Dr. John Crowell, of Haverhill.

He spoke of the need of a better education of the public mind on sanitary and hygienic topics, and referred to the advance that had been made in the past few years in this direction. Much remains to be done, however, and in no place, probably, is there greater room for sanitary reform than in country and seashore resorts and in country farm houses, to all of which physicians too often send their patients, without inquiring whether the most simple sanitary rules are complied with. Another great source of ill-health, among the people of this country, is poor cooking. Here we should take a lesson from the French, who seem to be able to produce better results from much scantier means. An idea of the contagiousness of diphtheria and kindred diseases, and the methods of preventing their spread, should be taught. Public funerals in cases of death from diphtheria, are still allowed.

Massachusetts is behind her sister States in laws to regulate the practice of medicine, and quackery is unhindred. The disgrace of a chartered bogus diploma-mill cannot, however, be repeated, laws having been passed in consequence of the discoveries of two years ago.

The reader closed with an appeal for better nursing among the people, for better ideas of feeding children, and a more earnest endeavor so to train the coming generation of the poor, that the present amount of misery may be materially lessened.

THE ANNUAL DINNER

was held in the Clarendon Street Skating Rink, nearly eight hundred Fellows being present.

Among the distinguished guests were His Excellency Gov. Robinson, Dr. Mackie, of New Bedford, Surgeon-General Holt, the Rev. Frederick Courtney, Samuel Eliot, Dr. George C. Shattuck, Dr. Henry I. Bowditch, Mr. H. O. Houghton; the president-elect of the Society, Dr. Charles D. Homans; the retiring president, Dr. Alfred Hosmer; Dr. S. A. Green, and Dr. H. P. Walcott, of the State Board of Health.

Dr. George B. Shattuck, the Anniversary Chairman, after dinner, called the meeting to order, and in a few well-chosen words congratulated the Society on its past and spoke of the second century of its existence on which it had now fairly begun, and which promises to be even richer in good work than the first. He introduced the newly elected president, Dr. Homans, as one who, from his associations and descent, should be able to prognosticate the future of the Society.

Dr. Homans spoke of the growth of the Society from 1789, when there were 68 members, against 1520 in 1884. More new members had been added during the past year than constituted the whole Society at the first-named period. At this rate of increase the Society would be a somewhat large body at the end of its present century.

Governor Robinson, on being introduced, was received with great enthusiasm. He welcomed the Society in the name of the people of the Commonwealth. With his education and skill, the physician is much to the community and to the State. No man educated to the practice of medicine has done his whole duty when he has taken care of the sick, reaped his profits, and settled down to the results. Ideas gained ought to stimulate to greater good, and to the discussion of great questions relative to the people at large. His relation to the science of "State medicine," the care of the poor, the insane, and the great questions of water supply and drainage, is an intimate one, and to him must the State look largely for guidance. The Governor then congratulated the Society on the step taken the day before in the admission of women, spoke of his desire to have only sound men appointed to the positions of medical examiners soon to be vacant, and closed with good wishes for the future of the Society.

Dr. Hosmer spoke of the recent establishment of the long-needed code of ethics, of the duty that each member of the Society owed to the Society and to the community, and of the self-respect that each must have to be a physician deserving of the name.

Remarks were made by Rev. Mr. Courtney, Dr. Crowell, Mr. Justice Field, and others. Adjourned.

MAINE MEDICAL ASSOCIATION.

Thirty-second Annual Meeting, held at Portland, June 10, 11, and 12, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 10—FIRST DAY.

THE meeting was called to order at 10.30 A.M. by THE PRESIDENT, DR. O. A. HORR, of Lewiston.

After prayer, the Association proceeded to the transaction of routine business.

THE TREASURER'S REPORT

presented a gratifying view of the financial condition of the Association. It was referred to an auditing committee.

DR. S. LAUGHTON, of Bangor, presented a report from

THE VISITORS TO THE MEDICAL SCHOOL OF MAINE,

which embodied a detailed review of the work in each department, and the school was, as usual, highly commended; it recommended the creation of two additional chairs, one of Histology, the other of Ophthalmology; also an increase of the course from a term of sixteen weeks to one of eighteen.

Favorable comment was made upon the new departure of having formal graduating exercises.

DR. S. P. WARREN, of Portland, presented an interesting paper, based upon an experience with

TWO UNUSUAL COMPLICATIONS OF LABOR.

Case I. Labor at term, complicated with acute pulmonary œdema, causing death.—Patient 35, multipara, gestation feeble, indefinite preceding history of "rheumatic fever" years ago. Bronchitis, probably subacute, began two or three weeks before expected confinement; slight œdema of extremities; spurious labor for two days prior to Friday evening, when dilatation began; pains were feeble through night, and dilatation little, requiring digital assistance. Morphia and chloral had no particular effect in checking cough or assisting labor. Cough increased as labor advanced, and was the immediate cause of inefficient contractions. Interference demanded to check growing suffocation and empty uterus. Before forceps could be applied, ergot quickened contractions and feeble female child born unaided. Little hemorrhage. Cough immediately increased; continued until patient was moribund from exhaustion and suffocation from long exudation. Large quantity of pinkish froth expectorated. Rallied under hypodermatic injections of whiskey and the use of digitalis and ammonia, warmth, etc. Death twelve hours post partum from probable heart clot.

Case II. Labor at seven months, complicated with fibroid uterus; eclampsia; septicæmia from sloughing fibroid; death on ninth day.—Patient 40, and first pregnancy; married seventeen years. Fibroma and probable pregnancy diagnosed four months before delivery. Eclampsia preceded by amaurosis and œdema; twelve convulsions; hypodermatic injection of morphia, a quarter of a grain, at lengthened intervals; digital dilatation and forceps extraction of stillborn male, weighing five pounds. Fibroma closed uterine canal and placenta being above it was extracted by hand above fibroma; no post-partum hemorrhage; no convulsions after dilatation of cervix was begun; urine boiled solid in test-tube; no casts; delirium previous post partum; conscious forty-eight hours after delivery; bichloride of mercury (1–2000) injections, quinia and stimulants every four hours; septicæmia on seventh day; death in uræmic coma on ninth day. Autopsy: Right Fallopian tube enlarged and inflamed; ovaries normal; acute peritonitis over right fundus uteri and in right iliac fossa; four ounces of pus in right periuterine sinuses; subperitoneal fibroid two inches in diameter on right cornu; three mural fibroids from two to four inches in diameter; cavity four inches long, filled with submucous fibroid, its mucous surface sloughing; uterine cavity empty; kidneys enlarged, pale, and showed lesions of chronic interstitial nephritis.

DR. T. A. FOSTER said that he believed that difficult labors might oftener find their cause in fibroids than was supposed, and advocated early relief.

In answer to the inquiry of Dr. Warren as to how many cases of œdema of the lungs had been observed by members, four were reported, and he believed the cause to be a dilated right heart.

APPLICANTS FOR MEMBERSHIP,

thirteen in number, appeared before the Board of Censors, and, on their recommendation, were elected to membership.

The Committee on Banquet reported that it was advisable to take no action this year, and asked to be discharged. After hearing a report from the Auditing Committee, the Session adjourned to 3 P.M., when, notwithstanding a rainy day, it was found that the attendance was greater than for many years.

AFTERNOON SESSION.

A Nominating Committee was appointed. Drs. F. A. Howe, of Newburyport and J. T. G. Nichols, of Cambridge, were introduced as *Delegates from the Massachusetts Medical Society;* they presented greeting from that Society, then in session in Boston.

DR. O. A. HORR, of Lewiston, the retiring President, then read his

PRESIDENTIAL ADDRESS.

After congratulating the Association upon its continued prosperity, he presented a retrospect of the work during its existence, and of measures accomplished by legislation for its own and the public good. Historical data valuable to the members of to-day, were recited, and the origin of many reforms which have been only recently accomplished, were noted; for example, the passage, by the Legislature, of the present anatomical bill. Members were urged to keep up the organization of the County Society, and suggestions were made for a nearer relation between them and the State Association. The removal of the Medical School of Maine, to Portland, was urgently pressed upon the Association, and the appointment of a committee to confer with the Trustees and the Alumni Association recommended.

Words of regret were expressed at Maine's backward position in matters of public health, but this is through no fault of the profession. A committee was subsequently appointed to consider the recommendations of the address, and, upon their suggestion, a Conference Committee was appointed to secure the removal of the Medical School to Portland.

DR. F. H. GERRISH read two papers:

A NEW METHOD OF RECORDING CASES.

The method provides for immediate notes in the presence of the patient, upon slips of paper, which are conveniently and easily filed, with such prescriptions as may be ordered, in envelopes, and then alphabetically laid away in pigeon-holes over the office-table, where they are always accessible. The system is claimed to be "complete, yet simple, easy to follow, inexpensive, convenient, labor-saving, protective against accidents in prescribing, capable of indefinite extension, and facilitates reference."

SOME NOTES ON ETHERIZATION.

DR. GERRISH stated that the notes presented had been prepared after the session of 1882, when Dr. Gordon, of Portland, stated that, by using two or three thicknesses of an old coarse towel well capped up over the face, with ether poured in small quantities upon the outside, he could in ninety per cent. of cases thoroughly etherize patients in three minutes. This at the time caused some incredulity among members, and he at once began a series of observations at the Maine General Hospital, in which were noted in 61 cases during the service of Dr. Gordon and others, with ether administered as proposed, the following data:

Longest time required, the shortest, the average time, and, incidentally, facts relative to the amount of ether used, and the behavior of the patient during and after.

The result in figures is—whole number,	61
Number etherized in 2½ minutes,	2
" " " 3 minutes or less,	5
" " " 4 " "	11
" " " 5 " "	13
" " " 6 " "	22
" " " 7 " "	27
" " " 8 " "	37
" " " 9 " "	45
" " " 10 " "	47
" " " 15 " "	55
Over 15 minutes,	6
" 20 "	2
" 30 "	1

Shortest time, 2½ minutes.
Longest time, 32 minutes.
Average time, 8.5 minutes.

Some statistics were submitted relative to the administration of ether after preparation by previous administration of bromides or some form of alcohol, and after no preparation.

In 23 cases after bromide preparation:

The average time was	13.6 min.
The shortest time was	8 "
The longest time was	30 "

In only 8 of these was there vomiting, during the administration of ether, or during or after the operation.

Per cent of cases vomiting at time of ether,	12.6
Per cent. vomiting,	34.7

In 16 cases after the alcoholic preparation:

Average time required,	8.1 min.
Shortest time required,	5 "
Longest time required,	20 "
Number vomiting at same time was	9 "
Percentage vomiting,	56.2 "

In 27 cases, after no preparatory treatment:

Average time required,	8.4 min.
Shortest time required,	4 "
Longest time required,	15 "
Number vomiting at same time,	17
Per cent. of cases vomiting,	62.9
Average time required for etherization in 127 cases,	9.3 minutes.

Dr. Gerrish was requested by the Association to further pursue his investigations on the administration of ether, and report at the session of next year

DR. H. E. HILL, of Saco, read a paper, reporting

SIX CASES OF OVARIOTOMY.

All were successful except one, death occurring from shock in four days. The heaviest tumor was forty pounds, the lightest twenty pounds. The highest temperature reached was 101½°. All the cases but one, and that the fatal one from shock, were operated upon by the Lister method. A special point made, was that these were from the practice of a general practitioner and not from that of a specialist.

DR. S. H. WEEKS stated that his best results in ovariotomy had been in private practice, notwithstanding the fact that his hospital experience was attended by arrangements for convenience and cleanliness surpassed nowhere.

The report of Dr. C. E. Webster, *Delegate to the Massachusetts Medical Society*, was received and read.

EVENING SESSION.

Dr. D. O. King, *Delegate from the Rhode Island Society*, was introduced and responded briefly.

PHOSPHORUS NECROSIS OF THE INFERIOR MAXILLA

was the title of a paper read by DR. WEEKS, of Portland, illustrated by exhibition of half of an inferior maxilla and the patient from whom it was removed. The appearance of the diseased bone suggested that the disease had obliterated the inferior dental artery, thus cutting off the blood supply to the bone.

Early and extensive operation was urged as the only certain means of cure, while general supportive measures and antiseptic washes were by no means to be neglected. Local irritation was regarded as the primary cause of the difficulty, and the constitutional suffering as secondary to it.

DR. WEEKS also read a paper on

OÖPHORECTOMY,

outlining the steps of the operation, the indications for its performance, and some facts bearing upon the results of these operations. It was regarded as a *dernier ressort* on account of its difficulties, dangers, and doubtful results. The writer believed that this operation would be less frequently called for in the future, just in proportion as we perfect our knowledge in the management of uterine and nervous diseases. A case was cited, the operation having averted impending insanity. The ovaries were found diseased. The right, cystic and of the size of an English walnut. The left, twice its natural size.

DR. GORDON believed, with the means of operating now at our command, that either Tait's or Battey's operation was safe. From his experience with a large

number of cases, he felt that the results certainly justified the operation. He preferred abdominal section, and before judging the results, time ought to be given to recuperate from the long nervous depression always existing.

DR. S. LAUGHTON, of Bangor, read a paper on

MICROORGANISMS,

based upon experimental study. The writer was evidently thoroughly convinced of the truth of Koch's theory, and cited a case in his own practice in which he had seen, by daily examination of sputa, the bacilli made to disappear by antiseptic inhalations. The sentiment of the Association seemed to be that the question is still *sub judice*.

WEDNESDAY, JUNE 11TH—SECOND DAY.

MORNING SESSION.

DR. SARAH ELLEN PALMER, of Portland, read a paper on

THE INDUCTION OF PREMATURE LABOR IN ALBUMINURIC RETINITIS.

The conclusion drawn was that although highly albuminous urine, dropsical effusion, and threatened convulsions may give way to recovery, yet the absence of these complications may only preclude death, when the only symptom has been loss of vision. Should not, then, this symptom be also a warning; and why may not labor be induced to save the mother's sight, when, from a series of reported cases, the unfavorable indications of this sudden blindness are so well established?

DR. J. A. SPALDING, of Portland, presented a supplementary paper, detailing the ophthalmoscopic appearance of the eyes in the case of Dr. Palmer's patient.

Dr. C. W. BRAY, of Portland, reported a case of

APOPLEXY IN A GIRL THIRTEEN YEARS OF AGE.

The autopsy revealed a recent clot in the middle lobe of the left cerebrum, and in the corresponding lobe on the right side a cavity filled with dark, urine-colored fluid. A microscopical examination demonstrated this to be an apoplectic cyst. It had no communication with any of the cavities or vessels of the brain, nor were there any tubercular deposits.

DR. J. A. DONOVAN, of Lewiston, reported

THREE SURGICAL CASES,

the first of special interest. A lad, ten years of age, was caught by a belt and whirled about a pulley some forty times, causing a fracture of the left parietal bone, a comminuted fracture of the left femur, with compound lower epiphyseal separation; the condyles of the right femur were denuded, and protruded through an extensive rent in the popliteal space about four inches; the left femur was fractured just below the trochanter major, the condyloid epiphysis separated, and the intervening shaft comminuted. Notwithstanding such extensive fracture the skin was not broken. The popliteal laceration was so extensive that the inner hamstring tendons were stripped of their investment, the saphena was exposed, and the artery displaced. The condyles were removed, when the shaft of the femur came into apposition with the knee-joint—certainly an unusual occurrence. The boy and exsected condyles were exhibited to the Association. There is good movement at the knee, and the growth of the limb is keeping pace with its fellow. The extensors of the leg are paralyzed from laceration of the nerve trunks, otherwise the boy did not seem to have seriously lost by his injury.

The second case was one of death from meningeal inflammation having its origin in chronic non-suppurative inflammation of the middle ear.

The third, an abdominal tumor having its origin behind and from the left kidney, resulted in death.

PROF. ALFRED MITCHELL, of Brunswick, presented a paper on the

PREVENTIVE TREATMENT OF PERINEAL LACERATIONS.

The points made were: 1st. Lengthening of the vaginal canal by bringing the perineum forward and downward by well-directed pressure. 2d. Keeping the centre of the arc described when the head passes through the vulva, well forward against the pubis.

DR. GORDON believed that the auxiliary forces of the abdominal muscles had much to do with causing parturient injuries; he did not allow them to be voluntarily exerted.

DR. O'BRIEN, of Bristol, said he wished to protest against the advice given by teachers to use several folds of a napkin for cleanliness to the hand; besides being a hinderance to the proper use of the hand, it wiped away the natural lubricant which kept the perineum moist, and soon proved itself, "like self-righteousness, a filthy rag."

DR. MERRILL, of Portland, exhibited a patient having a *Tumor in front of the Larynx, of Obscure Origin*, but apparently connected with the trachea.

AFTERNOON SESSION.

The Society proceeded to the

ELECTION OF OFFICERS,

with the following result.

President.—Dr. T. A. Foster, of Portland.

First Vice-President.—Dr. S. Laughton, of Bangor.

Second Vice-President.—Dr. Abial Libby, of Richmond.

Corresponding Secretary.—Dr. S. W. Johnson, of Dixmont.

Recording Secretary, Dr. Charles D. Smith, of Portland.

Board of Censors.—Drs. George H. Cummings, of Portland; B. F. Sturgis, of Auburn; E. Adams, of Litchfield; H. E. Hill, of Saco; A. L. Hersey, of Oxford.

DR. A. L. HERSEY, of Oxford, then delivered a scholarly oration, mainly a *resumé* of

MODERN MEDICAL THEORIES.

Many of them were regarded as far from proved. There has been far too much of the theoretical and too little of the practical; but now the old questions are reasserting themselves. The proper education of the people in sanitary and hygienic reforms should originate in the public schools. No physician can be too highly educated. Dr. Hersey is the first physician, himself not an instructor in a medical school, from the Maine Medical Association, to denounce the education of medical students in any other way than by thoroughly graded courses of study in medical preparatory schools. The address was received with marked interest, and a copy requested for publication.

A voluntary paper on *Carcinoma of the Breast*, was presented by Dr. Charles R. Crandall, of Portland.

DR. S. C. GORDON, Necrologist, reported the deaths during the year, of Drs. J. T. Gilman, of Portland; J. S. Goodwin, of Portland; C. W. Whitmore, of Gardiner, and Wm. Swasey, of Limerick; and presented by title an obituary notice of Dr. Whitmore.

EVENING SESSION.

DR. S. H. WEEKS presented a paper upon a case of injury to the eye resulting in

MONOCULAR DIPLOPIA.

The injury was a slight blow upon the bridge of the nose from a bat; slight injury was also inflicted over the right eye.

The patient was a boy twelve years of age. Although the eye was somewhat swollen, there was no apparent inflammation, and on the same evening he attended a public entertainment without any trouble from his eye; on the day following, he read continuously; on the third day he had photophobia. Three weeks from the date of injury, there were great photophobia, pain through the temple, and double vision limited to the right eye. The query arose, was it due to some change in the meridian of the cornea, or was it caused by displacement of the lens? The retinal vessels were congested; the fundus somewhat indistinct; the appearance of the retinal vessels and optic disk was apparently due to irregular refraction of the rays of light. The conclusion was that the irregularity of refraction depended upon a displacement of the lens. Astigmatic glasses had no effect upon the diplopia in any possible meridian of their axes. There are two important questions to be considered.

1. If due to displacement of the lens, why did not double vision immediately follow the injury?

2. Why, also, if displaced, did not the lens become opaque?

The Doctor's opinion was, as to the first query, that from a laceration of a portion of the attachment of the ciliary muscles, the lens was gradually displaced by the irregular action of the ruptured muscle of accommodation. As to the second query, it is known that, if the capsule be not ruptured, a lens may be displaced for months without becoming opaque.

There was never any inflammation of cornea, iris, or lens, and the media were always transparent. The treatment was early leeching of the temple, and the application to the eye night and morning of a solution of atropia, four grains to the ounce, with a view not only of dilating the pupil, but of putting at rest the muscles of accommodation. Tonic measures were also prescribed. After the relief of the disturbed condition of the eye, the diplopia still persisted, and was only relieved by the use of stenopæic glasses with a wide slit. The diplopia has never entirely disappeared, the original injury having been received in April, 1883.

DR. SPALDING considered this case one of great rarity. There were no changes in the media or fundus of the eye; it was doubtful whether the blow with the bat had excited so-called coarse alterations in the brain. He believed that in Dr. Week's case there must have been some cerebral commotion or hemorrhage excited by the blow. If extensive hemorrhage into the brain sometimes causes diplopia and death, why might not slight hemorrhage cause diplopia alone, which would disappear when the clot became absorbed? Simulation may be excluded, for so young a patient would not be likely to have heard of so rare a symptom as double vision; and hysteria is altogether improbable.

DR. WEEKS, in reply, said that the absence of any cerebral symptoms precluded the idea of cerebral hemorrhage, neither did the diplopia suddenly appear.

In reply to a query as to the position of the misplaced lens, Dr. Weeks said that the strong atropia solution used had put the ciliary muscle at rest, and allowed the fibres to heal; and thus the lens had been gradually drawn back into place, the rupture of these fibres not having been complete.

A paper by Prof. Weeks on *Ligation of the External Iliac Artery for the Relief of Femoral Aneurism*, was presented by title.

PROF. I. T. DANA then spoke upon

UNDEVELOPED TYPHOID FEVER,

taking the ground that, whereas in former years typhoid fever was definitely and typically developed, it has now, in the greater part of our State, become of less severity, not so well developed—in fact, "atypical."

DR. J. T. G. NICHOLS, Delegate from Massachusetts, said that in Cambridge there had been a steady decrease in both the frequency and severity of typhoid during the past twenty-five years. This he attributed to the improvement of sewerage and water supply; still it was a fact that in Boston and some other localities in Massachusetts, it had raged with frightful severity.

DR. HORR, the President, stated that while in most parts of Maine typhoid fever was infrequent, yet it was a fact that Lewiston, a large manufacturing city, was rarely entirely free from it, even in the cold winter months, yet it was surprisingly mild in type. Many other gentlemen took part in the discussion, and opinion seemed about equally divided as to the question of incomplete or undeveloped typhoid.

DR. O'BRIEN, of Bristol, reported that in his town typhoid had for years been of a very mild type, yet one of his families had removed to Provincetown, Mass., having a convalescent with it, and had there started an epidemic of remarkable severity.

DR. DANA feared that the disease was only quiescent, and would again appear with its old-time severity.

JUNE 12TH—THIRD DAY.

CLOSING SESSION.

Dr. Alonzo Garcelon, of Lewiston, presented a report as Delegate to the American Medical Association.

On motion of PROF. S. H. WEEKS, a committee of five was appointed to consider the propriety of extending an

INVITATION TO THE AMERICAN MEDICAL ASSOCIATION

to hold its meeting in 1886 in Portland. If that event ever takes place, the profession will take care of the Association, and furnish it with such accommodations for meetings as it has not had for ten years. Our hotels are numerous and first-class, and city and State pride would leave nothing undone. This was the universal sentiment.

Resolutions of congratulation at the success and prosperity of the Maine General Hospital were passed.

A committee was appointed, consisting of Dr. William Wood, I. T. Dana, and S. H. Weeks, to draft suitable resolutions on the

DEATH OF DR. JOHN T. GILMAN,

Ex-President of the Association, and the "father" of the Maine General Hospital. Dr. Gilman occupied a high place in the esteem of the profession of this State, and was widely known as an upright, learned, and public-spirited physician and citizen.

After the usual votes of thanks the Association adjourned, to meet in Portland on the second Tuesday in June, 1885.

The meeting was one of unusual interest; the attendance was larger than for many years. Twenty-three new members were added to the roll, and the work was uninterrupted by any elements of discord. In years past the Association meetings have been attended by representatives of various drug and surgical instrument firms, to whom was allotted space for exhibits. Circumstances of location have rendered these exhibits impossible during the past two years, and greatly to the benefit of the meetings. There are no outside attractions now to draw members from the hall to the ante-rooms and corridors, and members have made a business of attending the meetings. The sentiment of the Association strongly condemns a return to the old order of affairs, and the change is agreeably appreciated. The Maine Medical Association by no means objects to exhibits during its meetings, but much prefers them apart from its meetings.

MEDICAL SOCIETY OF NEW JERSEY.

One Hundred and Eighteenth Annual Meeting, held at Cape May, June 10 and 11, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 10TH—FIRST DAY.

THE one hundred and eighteenth annual meeting was convened in the Stockton Hotel, Cape May, on June 10th. The Convention was called to order by THE PRESIDENT, DR. S. WICKES, of Orange. After prayer by the Bishop, the Committee on Organization made its report, from which it appeared all the District Societies had paid their dues, and had returned a list of delegates as required by law. An unusually large attendance of delegates and invited guests was present. All the district societies, excepting Bergen, were represented by delegates.

DR. JAMES MECRAY, in welcoming the Society, said: There are many things of which we feel justly proud, our magnificent beach affording perfectly safe bathing by its very gradual descent, and regular, hard, smooth surface, with the fast land coming down to the very edge of the water. Our excellent, well-planned sewer system, laid down in almost every one of our streets, having sufficient fall to carry off all effete matters far away from the town, giving such a sanitary condition that the mortality of both city and county is the lowest of any in the State. This is not a thing in prospect, depending upon companies to complete, but "un fait accompli," and that by our own efforts. Our State Board of Health, through its Secretary, has expressed unqualified approval and commendation of our system.

Our water supply is in most excellent condition, furnishing about one million gallons daily, and distributed through all the most thickly settled portions of the town, giving an abundant supply of pure, fresh water, not from surface springs, but drawn from the very bowels of the earth, and stored in three large tanks, and from them distributed through mains to every part of the city.

We will not consume your time by mentioning facts relative to our humidity, temperature, and prevailing winds, but would refer to a very able report of Prof. Smuck, Assistant State Geologist, well worth perusal by all seeking healthful, pleasant resorts either summer or winter. Some remarkable facts are brought to light in this report, giving us the advantage over all other seaside resorts in equableness of climate in this country with the single exception of Key West.

His Honor, the Mayor of Cape May, followed in a pleasing address, cordially welcoming the members of the Society to the hospitality of the city.

The Committee appointed at the last annual meeting to

AUDIT TREASURER'S ACCOUNTS,

reported a balance of $1644.22, of which $1550 are invested in United States four per cent. bonds, $182.81 in cash remaining in the Newark Saving Institution, and $88.99 in the hands of the Treasurer.

As directed by the Society, the Treasurer has furnished a bond to the amount of $5000, which is now in possession of the Secretary.

The report was adopted, and the Treasurer was instructed to exchange the United States four per cent. bonds for United States registered bonds.

EVENING SESSION.

The Corresponding Secretary presented his report.

THE TREASURER'S REPORT.

The Committee on Treasurer's accounts subsequently reported the amount to be correct, and they recommended that the assessment of the District Societies for next year be $1.50 per capita.

The report was adopted and Committee discharged.

THE PRESIDENT, DR. STEPHEN WICKES, of Orange, in his annual address, took for his theme

LIVING AND DYING, ITS PHYSICS AND PSYCHICS.

He described the various modes of death by the head, by the heart, and by the lungs. He delineated the various symptoms occurring in each mode, and drew attention to the importance of the physician fully appreciating the meaning of the symptoms and recognizing the dangers, in order that he might be more effective in warding them off. He then described these different symptoms more definitely, as well as the signs of impending dissolution and of actual death.

THE REPORT OF THE STANDING COMMITTEE

was then presented by DR. T. J. SMITH, Chairman.

In review of the reports of the county societies, the medical history of the year may be epitomized as follows:

First. A diminished amount of disease throughout the State. *Second.* Epidemics have not prevailed to any great extent, and were of diminished intensity. *Third.* Diseases of the respiratory organs, though common, were observed in less severe forms, and were

more than usually amenable to treatment. *Fourth.* An extraordinary freedom from diseases of the intestinal canal. *Fifth.* Less scarlatina, diphtheria, and other cases of contagious disease, except measles, which was unusually prevalent. *Sixth.* Fevers, which always call for a large share of professional attention, have nowhere shown a marked fatal tendency.

In therapeutics the committee note a tendency to use quinia in large doses. The salicylates and aconite are widely recommended in rheumatism. A case of congestive chill relieved by venesection to twelve ounces was reported by Dr. Morris.

The use of digitalis in teaspoonful doses of the tincture is recommended in typhoid fever; such medication causing relief from delirium and favoring sleep. The observer who reports its use has seen none of the cumulative effects of the drug.

From Essex are reported two cases of rectal anæsthesia. In these cases all the reputed advantages were apparent, but in both cases were followed by serious symptoms of intestinal irritation.

Dr. Dorms reported a case of omental encephaloid disease not diagnosticated ante-mortem, but associated with cerebral symptoms. Dr. Carll reported two cases of abscess in the neighborhood of the colon, discharging by the rectum, and another of abscess between the liver and diaphragm, discharging by the lungs.

As items of professional interest, were noted the establishment of a course of instruction in the Newark Eye and Ear Infirmary by Dr. Kipp. The publication of the *Archives of Pediatrics*, by Dr. W. P. Watson, of Jersey City. The establishment of the Burlington County Hospital, and of the Newark City Hospital. St. Barnabas Hospital is also to be enlarged.

The prevalence of malaria at the Newark Reform School, and its apparent connection with a polluted supply of drinking water, is reported by Dr. Whitehorn.

WEDNESDAY, JUNE 11TH—SECOND DAY.

THE SPECIAL COMMITTEE ON EDUCATION

presented the following:

Resolved, That this Society approve and adopt the recommendations of the Special Committee on the curriculum of preparation to be required of persons contemplating the study of medicine in this State, as contained in the report presented at the last annual meeting of this Society.

That to carry out the recommendation of said report in regard to a censorship, as therein contemplated, this Society is of opinion that two Boards of Censors be appointed by the Standing Committee, each year, consisting of five members of this Society, one for the northern and one for the southern part of the State; to whom should be presented for approval the credentials of all persons proposing the study of medicine, and in case of the insufficiency of such credentials to examine the applicant in the branches of science and learning indicated in the report of this Committee.

That the Standing Committee prepare and report to the Society for its adoption, such amendments of its by-laws as are necessary to carry out these plans and recommendations of this Committee.

That the Corresponding Secretary communicate the action of this Society on this subject to the district medical societies in this State, with instructions to adopt such regulations as shall effectually secure the observance, in their several localities, of the measure adopted by this Society.

That the Corresponding Secretary communicate the action of this Society on this subject to the State medical societies of the several States of the Union, and respectfully request their coöperation with us in this effort to elevate the standing of medical education throughout the country.

The resolutions, after considerable discussion, were adopted.

On motion of DR. E. M. HUNT, the following resolutions were adopted:

Resolved, That the Special Committee on Education be continued, and be requested to report next year to the Society, what is feasible to be done to test the competency of graduates of various medical colleges who hereafter seek to settle in this State.

On motion of DR. HUNT, it was

Resolved, That a committee of three be appointed by the President, to report this afternoon, what in its judgment can or ought to be done by county medical societies or by local officers, to prevent unlicensed persons from practising in this State. The following were announced as the committee: Drs. Parrish, Pennyton, and Welch.

A REPORT ON MEDICAL JURISPRUDENCE

was presented by DR. GARRISON. The report urged the necessity of having expert witnesses, recognized as such in the eye of the law, and also urged that expert witnesses be employed by special selection.

After some discussion, the report was referred back to the Committee on Amendments.

In connection with this subject, DR. E. M. HUNT offered the following, which was adopted:

Resolved, That this Society recognize the importance of some legislation as to the best modes of securing expert witnesses.

The Committee on

ARMY MEDICAL MUSEUM AND LIBRARY

of the Surgeon-General's Office, presented the following:

Whereas, It is the opinion that the Medical Museum and the Library of the Surgeon-General's Office at Washington, D. C., have been largely instrumental in the advancement of sound professional and scientific knowledge, and that they give promise of still greater usefulness in the future, and

Whereas, It is learned with regret, that both these collections are in great jeopardy from fire or accident through the insecurity and unsuitableness of the building in which they are now stored; it is

Resolved, That Congress be respectfully urged to provide suitable indestructible quarters for these invaluable treasures, to secure them against any possible contingency of loss or damage.

Resolved, That it is the sense of this meeting, that the management of these national collections has been eminently successful in the past, and that any change of administration would not only be injurious to these interests, but would cast an undeserved stigma upon the office of the Surgeon-General of the Army.

Resolved, That we again respectfully petition Congress

to provide suitable annual appropriations for the increase and preservation of the Museum and Library, and also for carrying on the valuable *Index Catalogue* of the Surgeon-General's Office.

Resolved, That a committee of three be appointed by the Chairman of this Society, to prepare a suitable memorial, which shall be printed and sent to each of our Representatives in Congress.

The following committee was appointed by the President: Drs. B. A. Watson, H. G. Taylor, and E. M. Hunt.

DR. PARRISH, on behalf of the

COMMITTEE ON LUNACY

in the State of New Jersey, made a full report, and recommended the following, which were adopted:

Whereas, The Legislature of the State of New Jersey having, at its session of 1883, passed an Act entitled, "An Act to create a Council of State Charities and Correction," it is deemed of sufficient importance to the health and well-being of the people as to call for congratulations by the Medical Society of New Jersey; therefore,

Resolved, That the Medical Society of New Jersey, in annual meeting assembled, at Cape May, June 10th and 11th, 1884, welcome the appointment by the Governor of the State of a Council of State Charities and Correction, as an additional and coöperative factor with the Medical Society in correcting the neglects and abuses to which the insane poor of the State are subjected, especially in the County Almshouses throughout the State;

Resolved, That in congratulating the community upon the existence of such a Council, the Medical Society of the State, the District Societies in the different Counties, and individual physicians in their respective homes, will cheerfully coöperate with said Council in all suitable and legitimate plans to secure the results contemplated by law.

DR. C. J. KIPP, Third Vice-President, then read an essay on

THE PREVENTION AND TREATMENT OF PURULENT CONJUNCTIVITIS.

He said that the treatment which he had found most useful in the purulent ophthalmia of the new-born, consists of cold applications to the lids, and frequent cleansing of the eyes with tepid water, to which may be added boric acid, carbolic acid, permanganate of potash, the bichloride of mercury, or other disinfectants. He has found simple water as efficacious as the solutions named. Nothing else is done till the swelling of the lids has somewhat subsided, and they can be everted without difficulty; the conjunctiva has ceased to be smooth and lustrous, and is succulent and relaxed, and the discharge is no longer serous and of a straw color, but is decidedly thick and creamy. When this stage has arrived, he begins with daily applications of a one per cent. solution of the nitrate of silver, and if this is not followed by severe reaction, and the discharge continues profuse, he substitutes a two per cent. solution for the weaker one. As a rule, one application in twenty-four hours is sufficient, but in cases in which the discharge is very profuse, and the swelling of conjunctiva excessive, the solution is applied every twelve hours, until a marked improvement is apparent; after that the application is again made once every day, and later a one per cent. solution is again substituted. Under this mode of treatment the author has not lost a single case that came under his care during the first days of the disease. After describing the affections of the cornea which are found in cases which have been neglected or maltreated, he advised the use of atropia and eserine in addition to the nitrate of silver application, which should be continued, whether affections of the cornea are present or not, as long as the discharge is copious.

With regard to prophylaxis, the author thinks that inoculation can be prevented by carefully wiping the eyelids of the infant immediately after birth, and by thoroughly cleansing the conjunctival sac with plenty of clean tepid water in cases in which the mother is known to have a vaginal discharge. He advocates the dissemination of knowledge among the people as to the causes and the curability of this disease under proper treatment, and the great danger of hopeless blindness from neglecting this disease. He thinks that the State Board of Health should take hold of this matter.

Gonorrhœal conjunctivitis he has treated in about the same way as the ophthalmia of the new-born, and, in addition, has often in the first stages of the disease applied leeches to the temple. In severe cases he has also scarified superficially the conjunctiva immediately after the cauterization. To relieve the pressure of the lids, he has divided the outer canthus by means of scissors. Corneal affections arising in the course of the disease do not, in his opinion, contraindicate the use of caustic. Infiltrations in the cornea call for atropine, and deep ulcers for puncture of the floor of the ulcer and the pressure-bandage. Although the caustic treatment does not by far give as good results in this form of purulent conjunctivitis as in ophthalmia neonatorum, it is superior to every other mode of treatment which the author has tried. In cases in which one eye was affected at the time the case came under treatment, the author formerly sealed up the sound eye with a pad of cotton-wool and adhesive plaster; more lately he has made use of Dr. Buller's shield of mackintosh with a hole in the centre, in which is inserted a watch-glass, to enable the patient to see. With intelligent and cleanly patients, there seems to be but little need for such protection, as is seen from the fact that in all (nine) cases of gonorrhœal conjunctivitis of one eye only which he has treated in the last few years, the disease did not attack the other eye, although no other precaution was taken than to warn the patient and the nurses against inoculating the sound eye. To show that these cases were not mild ones, it is stated that in only one of them did the cornea remain intact; in five the cornea was totally destroyed; and in the other three it was seriously damaged.

DR. GEORGE T. WELCH then read an essay on *Many Drugs and Few Remedies*.

Drs. Thomas Addis Emmet and Isaac E. Taylor, of New York, having been duly recommended by the committee, were elected

HONORARY MEMBERS

of the Society.

A MEDICAL SOCIETY IN CAPE MAY.

A petition from the physicians of Cape May, asking for a commission to organize a medical society in that county, was received, and on motion it was ordered that a commission be granted.

Drs. Wickes, W. P. Watson, and E. M. Hunt were appointed the Committee on the "Fellow's Prize Essay," and they were instructed to select a subject for the essay, and publish the same in the medical press.

The following were then elected

OFFICERS FOR 1884:

President.—P. C. Barker, M.D., of Morristown.

Vice-Presidents.—Drs. Joseph Parrish, C. J. Kipp, and J. W. Ward.

Recording Secretary.—Dr. Wm. Pierson, of Orange.

Corresponding Secretary.—Dr. Wm. Elmer, Jr., of Trenton.

Treasurer.—Dr. W. W. L. Phillips, of Trenton.

Standing Committee.—Drs. T. J. Smith, E. J. Marsh, and D. C. English.

It was voted that the next annual meeting of this Society be held at Long Branch, on the second Tuesday in June, 1885.

Dr. H. H. James was appointed *Essayist* for the next meeting.

THE PRESIDENT appointed the following *Committee of Arrangements* for the next annual meeting: Drs. S. H. Hunt, H. R. Baldwin, D. M. Forman, W. H. Shipps, and Henry Mitchell.

After the adoption of the usual votes of thanks, the Society adjourned.

OHIO STATE MEDICAL SOCIETY.

Thirty-ninth Annual Meeting, held at Columbus, June 10, 11, and 12, 1884.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, JUNE 10TH—FIRST DAY.

THE Society convened in Lyndon Hall, and was called to order at 2 P.M., by the PRESIDENT, C. P. LANDON, M.D., of Westerville.

Rev. Colonel Anderson opened the session with prayer, after which THE PRESIDENT, in a short and appropriate address, thanked the members for the honor of his election, and called attention to the important questions which would come before them for discussion.

THE SECRETARY, DR. COLLAMORE, of Toledo, presented his Annual Report, from which the unwelcome fact is learned, that twenty of the auxiliary societies have abandoned their organizations. It is, however, fair to state, that many of these have been defunct for several years, and that some are replaced by other organizations acting in harmony with the State Society.

DR. SHARP, of London, introduced the following resolution concerning the establishment of a

STATE BOARD OF HEALTH,

the discussion of which and kindred resolutions, occupied more than one-half the working hours of the meeting.

Whereas, There are now pending in the two houses of the Legislature of Ohio, different bills, having for their purpose the establishment of State boards of health and medical examiners; therefore, be it

Resolved, That a committee of five be appointed, to which these several bills shall be committed for revision, and which shall report such revised bill for adoption by this Society, on Wednesday morning.

The committee was composed of Drs. Sharp; Weaver, of Dayton; Reed, of Hamilton; Gill, of Cleveland; and Baldwin, of Columbus.

REPORT OF DELEGATE TO THE AMERICAN MEDICAL ASSOCIATION.

DR. DUNLAP, of Springfield, made a verbal report, dwelling chiefly upon the work of the Section on Obstetrics and Diseases of Women. His remarks led to the discussion of the treatment of the pedicle, in the removal of uterine and ovarian tumors, and was participated in by Drs. Reeve, of Dayton and Sutton, of Pittsburg, Pa. The latter spoke upon invitation, and was subsequently elected to honorary membership.

The session was closed with a paper on *The Races*, written in blank verse, by Dr. Wark, of Ontario.

EVENING SESSION.

The Society was called to order by VICE-PRESIDENT, DR. E. SINNETT, of Granville.

By special action of the Committee of Arrangements, this session was devoted wholly to the subject of

MEDICAL LEGISLATION AND EDUCATION.

DR. SHARP opened the discussion with an able and convincing written argument in support of the following resolution, of which he was the author.

Resolved, That the public good and the higher interests of the Medical Profession would be promoted by the establishment of a State Board of Medical Examiners; that such Board shall be independent of all Medical Schools, and be empowered to examine and pass upon the moral fitnesss and literary and medical attainments of all applicants for admission to the practice of medicine, and to grant license to practise medicine in the State of Ohio, to such only as shall have passed a satisfactory examination before said Board; that Medical Schools shall continue their functions of teaching and conferring degrees of M. D. only, with no powers whatever to grant license to their graduates, admitting them to the practice of medicine.

The discussion gradually drifted into a comparison of the several bills now before the Legislature. The debate was generally participated in by the members, and consisted largely in a repetition of the stock arguments on such occasions. The session closed without reaching a vote.

WEDNESDAY, JUNE 11TH—SECOND DAY.

MORNING SESSION.

Discussion was continued upon Dr. Sharp's resolution for the establishment of

A STATE BOARD OF MEDICAL EXAMINERS,

until finally, a vote being taken, it was carried by a large majority. Immediately following this vote, the Special Committee appointed to report back a medical bill which should harmonize all interests, submitted the fruits of their work.

The bill provides for the appointment by the Governor of a State Board of Examiners of nine reputable physicians, graduates of legal medical colleges, and who have practised medicine for not less than ten years, but none of which shall be connected with any medical school or college. Each of the State societies, representing the different schools of medicine, submits fifteen names, from which the Governor selects the nine composing the board. Of these nine members, three serve in the first organization for three years, three for four, and three for five years. At the expiration of the terms fixed above, all appointments shall be for a term of five years. The board shall examine all applicants, irrespective of diplomas, for license to practise medicine or surgery in this State. The bill makes no provision for a State Board of Health.

The bill as reported by the Committee is essentially the same as that now before the Legislature, and generally known throughout the State as the Scott Bill. It has already been endorsed by many local societies.

A hot discussion at once began. The bill was opposed for many reasons, the more prominent ones were that the appointing power being vested in the Governor the Board would speedily degenerate into a political machine, and because of the proviso which excludes members of medical college faculties.

DR. REAMY, of Cincinnati, took the ground that the members of the Board of Examiners should also be examined in order to determine their competency to discharge the duties of State Examiners, and offered the following amendment to the report of the Committee:

Provided, That no man shall serve on said Board until he has won his position by a competitive examination made by a committee appointed by this Society; said examination to be conducted orally and in public, at the capital of the State.

Amid considerable excitement the report was laid upon the table, not because a majority were opposed to it, but simply because the patience of the members was exhausted by the length of the discussion.

DR. KINSMAN, of Columbus, then read a report upon

TUBERCULOSIS.

The following conclusions were stated: Tuberculosis may be communicated by inoculation, ingestion, or inhalation of tuberculous matter. Tubercular processes in man and animals are identical. It seems proved that the bacillus tuberculosis is the active infectious agent. It is probable that we are acquainted with two forms in the life-history of this parasite, the rod and the spore, and the injection of either will produce bacillar lesions. The capacity for aërial infection seems to be the only test for *true* tuberculosis. For the occurrence of tuberculosis in any given case two factors are necessary, the proper soil and the infectious agent. The first, which we call predisposition, is either hereditary or acquired. By conceding the bacillus as a factor, we are not logically required to address our treatment to this factor alone, but, as heretofore, we must use all means to extinguish the predisposition. For the present, the only means at command, in the treatment of the second factor, is to regard every patient as a focus whence contagion may arise, and by the systematic collection and destruction of his bacillus-bearing excreta, prevent the access of the germ to other persons who are predisposed to consumption.

AFTERNOON SESSION.

THE PRESIDENT delivered his *Address*, which fully met the expectations of his many friends. The several live medical issues of the day were ably and eloquently discussed.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—J. C. Reeve, M.D., of Dayton.

Vice-Presidents.—E. B. Pratt, M.D., of Mt. Sterling; B. W. Davis, M.D., of Marion; C. R. Merriman, M. D., and J. F. Baldwin, M.D., of Columbus.

Secretary.—G. A. Collamore, M.D., of Toledo.

Assistant Secretary.—C. E. Brush, M.D., of Zanesville.

Treasurer.—T. W. Jones, M.D., of Columbus.

In the *Committee on Admissions*, the two vacancies were filled by the election of Drs. Reed, of Hamilton; and Fowler, of Delaware.

Committee on Publication.—Dr. Conklin, of Dayton, was elected to fill the vacancy.

Dr. Reed, of Mansfield, to the *Committee on Ethics;* and Dr. Herrick, of Cleveland, to the *Committee on Medical Legislation.*

Upon invitation of the Montgomery County Medical Society, Dayton was named as the *place of meeting in 1885.* The *date* was subsequently fixed on the first Wednesday in June, 1885.

DR. BEACH, of London, offered a resolution of sympathy for Dr. John B. Thompson, of Columbus, one of the charter-members of the Society, who is prostrated by sickness with little hope of his recovery. The resolution was passed unanimously.

THE COMMITTEE ON ETHICS

now made its report, sustaining the charges of unprofessional conduct against Dr. E. C. Lewis, of Canal Dover, and recommending his expulsion from the Society. One of the charges upon which the Doctor was found guilty, was that of procuring an insurance, in his own name, on the life of a patient at that time under his care with cancer of the uterus. The finding of the Committee was accepted without discussion.

DR. W. J. SCOTT, of Cleveland, then read an interesting report upon *Impurities in Drinking Water.*

DR. S. F. FORBES, of Toledo, presented a paper on

THE NECESSITY FOR THE RADICAL OPERATION IN EMPYEMA.

He urged the importance of early operation, and maintained that a large proportion of the unsuccessful results were due to delay in operating. He makes a free incision in the chest-wall, and washes out the cavity with a weak solution of carbolic acid. In cases operated on early, he believes the employment of the drainage-tube generally unnecessary, and occasionally leading to the formation of troublesome fistulæ.

ENTERTAINMENTS.

In the evening the members were elegantly entertained by Drs. Starling, Loving, and J. W. Hamilton, at their respective residences.

THURSDAY, JUNE 12TH—THIRD DAY.

MORNING SESSION.

Immediately after the reading of the minutes

THE IRREPRESSIBLE MEDICAL LEGISLATION QUESTION

again came up, and on motion of DR. X. C. SCOTT, the report of the Special Committee was taken from the table.

On motion of DR. WEAVER, the amendment of Dr. Reamy was stricken out, and, amid much applause, the report as originally presented was adopted.

THE PRESIDENT promptly appointed the following Committee to look after the interests of the bill and urge its passage by the Legislature:

Dr. X. C. Scott, of Cleveland; Dr. J. J. King, of Bing Hill; Dr. J. M. Weaver, of Dayton; Dr. H. J. Sharp, of London; Dr. W. H. Phillips, of Kenton; Dr. C. A. L. Reed, of Hamilton; Dr. D. N. Kinsman, of Columbus; Dr. J. F. Baldwin, of Columbus; and Dr. G. T. Franklin, of Chillicothe.

THE COMMITTEE ON FINANCE

reported the accounts of the Treasurer correct, and a balance in the treasury of $800.82. The Committee fully exonerated Dr. J. F. Baldwin from the anonymous charges made against him some time since in one of the Columbus papers. The charges were investigated at the request of Dr. Baldwin, although the action of the Society in keeping him in office was sufficient refutation, without the formality of an investigation.

DR. H. P. ALLEN, of Columbus, then read a carefully prepared paper on

THE PUPILS AS A FACTOR IN DIAGNOSIS AND ETIOLOGY.

He entered quite lengthly into the anatomy and physiology of the optic nerve tracts and the pupils. He illustrated fully the well-known proposition, that all conditions which cause pressure on the brain are attended with dilatation, and that all irritative conditions cause contraction of the pupils.

DR. R. HARVEY REED followed with a paper on

IRRITATION OF THE PROSTATE.

The author described three forms of irritation, congestive, catarrhal, and nervous, each of which is not manifested by the constitutional disturbunces, or destructive changes in the gland, such as characterize acute prostatitis on suppuration. The causes of irritation of the prostate were given as masturbation, excessive sexual indulgence, venereal diseases, exposure, and traumatisms. It frequently results in impotency.

The treatment is tonic, alterative, and sedative, with such local applications as the condition may suggest.

Dr. J. W. Craig, of Mansfield, read an interesting paper, based on a large personal experience in the *Treatment of Varicose Veins*.

DR. W. M. BEACH'S report on *Milk Sickness* was an exhaustive study of the subject. The author has had large experience in this rare disease, and ranks as one of the authorities upon it. His views are already familiar to the profession through former articles, especially the paper before the American Medical Association in 1883.

AFTERNOON SESSION.

Owing to the fact that but a few hours yet remained before the final adjournment, the following papers were read and referred, without discussion, to the Committee on Publication.

DR. JOSEPH RANSOHOFF read a paper on

SANGUINEOUS CYSTS OF THE NECK.

The paper was based upon a case of which a photograph and specimen were presented. The tumor was of fourteen years' growth, and extended from the mastoid process to the sternum. It was of the size of two fists. Fluctuation distinct. Subdivided into two parts by the sterno-mastoid muscle. Did not disappear, nor was it reduced in size by pressure. Aspiration yielded almost pure blood. Extirpation was practised and the patient made an excellent recovery. Examination of the cyst showed it to be thin-walled and lined in many places with flat endothelium. The internal surface was smooth in places, and in others presented trabeculæ like the chorda tendinæ of the cardiac ventricles. Valve-like folds were also present. The author believed this tumor to be a primary sanguineous cyst. Where extirpation can be practised, he preferred it to aspiration or incision. The former is not devoid of danger and rarely successful, and incision often leaves fistulæ which fail to close.

Dr. Landon now presented DR. REEVE, PRESIDENT-ELECT, to the Society, who in a few well-chosen remarks returned thanks for the honor, and proceeded to read a paper entitled,

HISTORICAL AND CRITICAL NOTES ON THE MANAGEMENT OF THE THIRD STAGE OF LABOR.

Apologizing for occupying attention with a subject apparently so trivial, he found necessity for reconsidering it in recent practices. Papers had appeared in the journals within a year advocating removal of the placenta immediately after birth of the child, and at Strasburg they had lately been pursuing the plan of allowing it to remain until thrown off by the natural process. Both plans had been practised in the past, as shown by extracts from writers of the last century: both had been abandoned on account of disastrous consequences. The influence of delivery of the after-birth in causing inversion of the uterus was treated of at length, and the fact emphasized that uterine inversion as a spontaneous act of the organ itself, was not sufficiently recognized by the profession. If delivery of the placenta ever contributed to inversion of the uterus, as it certainly did, the now popular mode of expression known as Credé's method, was equally, if not more, liable to cause the accident than the vulgar midwife's plan of pulling at the cord. Dissatisfaction with Credé's method was shown by quotations from recent writers. Finally, no management of the third stage of labor could be scientific, which was limited to a single plan, and that did not, above all, take into consideration the character of the preceding stage of labor.

DR. W. J. CONKLIN, of Dayton, next presented a paper on

THE REMOTE EFFECTS OF CONGENITAL PHIMOSIS.

The author stated that ordinarily no bad consequences result from this deformity, but exceptionally it is the

initial factor in the causation of many grave local and constitutional disturbances. Disturbances of the genito-urinary organs are frequent sequelæ of a neglected phimosis. The irritable penis was considered to be a characteristic feature of a pathogenetic phimosis. Perhaps the most interesting portion of the paper was that which referred to the disorders of the nervous system which are occasionally associated with and dependent upon a neglected congenital phimosis. Cases of convulsions, incoördination of muscles, chorea, and paralysis were related, which had been promptly and permanently relieved by circumcision.

A case of chorea and total paraplegia, recently under the care of the writer, deserves a more extended notice. A boy of eleven years was afflicted with a fully developed but severe chorea, limited to the lower extremities. In a few days, the muscles of the face and arms were involved. Soon after, he became paraplegic. His penis was undeveloped, the prepuce elongated, and the preputial opening barely large enough to admit the smallest probe. Circumcision was advised and refused. For twelve weeks he did not walk a step or stand upon his feet. His parents, finally alarmed at his condition, consented to the operation. The chronic manifestations ceased immediately after the circumcision, and in forty-eight hours he walked without the slightest impairment of muscular power. The author strongly urged the necessity of closely examining the penis in all obscure nervous and bladder troubles in young children.

The next paper was by DR. N. P. DANDRIDGE, of Cincinnati, on

FOREIGN BODIES IN THE URETHRA.

The paper recited the histories of two cases in the writer's practice. In the second case, a bullet was extracted from the urethra, thirteen years after a gunshot wound in the groin. The patient came to the hospital complaining of a stricture. Exploration revealed a foreign body behind the peno-scrotal angle, which was removed by external incision, and proved to be the bullet. The statistics of gunshot wounds of the bladder, given by Bartels, and the cases found in the *Surgical History of the War*, were briefly analyzed. The treatment was thus summed up: An attempt should be made, in all cases, to extract the foreign body through the meatus. If not successful, and the body is in the deep urethra, it may be gently pushed into the bladder, provided it is not too hard for the lithotrite to crush. If stricture exists, a bougie should be passed, if possible, and allowed to remain for some hours, and often the stone will escape when it is withdrawn. If the introduction of the instrument is not possible, all strictures in the anterior portion of the canal should be cut by internal urethrotomy, but in the deeper part external urethrotomy alone should be practised. Finally, an incision is necessary when the above means fail, and should always be resorted to when the body has been impacted for a long time, for fear that ulceration of the urethral wall should occur, and lead to infiltration of urine.

DR. C. A. L. REED, of Hamilton, read a paper on

DISEASES OF THE FEMALE URETHRA.

The treatment recommended for follicular urethritis was division and subsequent cauterization of the urethro-follicular septum, thus practically obliterating the follicles of Skene, the seat of the disease. Several cases of granular urethritis were cited, and their treatment by the curette, or curette-forceps, and subsequent application of mild astringents advised. Urethritis depending upon adenomata and neuromata was treated by removal of the adventitious growths. The buttonhole operation of Emmet was successfully practised where the disease was due to prolapsus of the membrane. Kolpocystotomy was looked upon as the essential element of successful treatment in cases of simple urethritis of long standing, associated with infiltration and induration of the periurethral cellular tissue. The removal of this latter condition is best secured by copious intraurethral injections of hot water.

Dr. H. Z. Gill, of Cleveland, read an interesting report on *Restoring the Ruptured Perineum.*

DR. D. W. GREENE, of Dayton, presented a paper on

THE USE OF BOROGLYCERIDE IN THE TREATMENT OF SUPPURATIVE EYE AND EAR DISEASES.

The antiseptic properties of this new remedy were illustrated by its use in surgery and gynecology. The author from personal experience spoke favorably of its use in granular and catarrhal conjunctivitis, ophthalmia neonatorum, and ulcer of cornea.

He further endorsed it as a valuable remedy in suppurative inflammations of the middle ear. Nothing in the author's experience so promptly removed the fector of the discharges. A fifty per cent. solution in glycerine was the strength ordinarily advised.

After passing the usual complimentary resolutions to the officers, the Society adjourned to meet in Dayton on the first Wednesday of next June.

NEWS ITEMS.

BALTIMORE.

(From our Special Correspondent.)

THE ACTION OF CARBOLIC ACID, ATROPIA, AND CONVALLARIA ON THE HEART OF THE FROG AND TERRAPIN.—From some very interesting experiments with carbolic acid, atropia, and convallaria on the heart of the frog and terrapin, made at the Johns Hopkins University, DR. H. G. BEYER, U. S. N., has been able to draw some very important conclusions, of which we will here give a short summary:

I. *Carbolic acid* acts as a cardiac depressant from beginning to end, and is in no way a stimulant to the heart, as has been supposed by some. A steady stream of highly oxygenated blood being supplied to the heart, it takes a very considerably larger dose of the drug before its characteristic poisonous effects are produced than when only moderately oxygenated blood is used, apparently showing the great importance of keeping up the respiratory activity in cases of carbolic acid poisoning. Any effects produced by carbolic acid other than depressant are due to other causes, probably to primary stimulation of the respiratory centre in the medulla.

II. *Atropia.* So far as atropia is concerned, Dr. Beyer has added strong additional proof of the powerfully stimulant influence which is exerted by this drug over the action of the heart, which action, he thinks, has

hitherto not been sufficiently insisted upon, nor been so generally recognized as it deserved. This stimulant action is particularly well shown in one of the experiments in which the auricular portion of the heart was from the beginning in an atonic condition, and both auricles, therefore, remained almost completely passive, though distended with blood, while the ventricle was actively contracting. After atropinization both auricles commenced to work admirably, expanding fully and contracting completely; consequently the total amount of work done by the heart was double that which it was under normal blood. This experiment, in which the heart was kept under observation for seven hours and thirty-five minutes, includes nine atropinizations, each with the same result, namely, of inducing the passive and over-distended auricles to resume work in the most perfect manner, and thus increasing considerably the total amount of work done by the entire heart. Dr. Beyer has furthermore investigated the physiological antagonism supposed by Prof. Bartholow and Dr. A. C. Post, of N. Y., to exist between atropia and carbolic acid, and has found that, after the heart had been completely or almost completely paralyzed by carbolic acid, it resumed its normal activity in much less time, when allowed to recover under the influence of atropinized blood than under normal blood. This antagonistic action between these two drugs is more particularly well shown in the manometric tracings on the drum taken during the recovery of the heart under these two different conditions, so that the physiological antagonism between atropia and carbolic acid may be regarded as an established fact, so far as the heart is concerned.

III. *Convallaria.* From the large number of experiments with convallaria on the heart, Dr. Beyer formulates his conclusions somewhat as follows, viz.:

1. It increases its rate.
2. Slightly increases its work done.
3. Raises intracardiac and aortic pressure.
4. Arrests both auricles and ventricle in systole.
5. Large doses arrest the heart at once.
6. Produces its results most probably by its direct action on the muscular substance of the heart.
7. Has a very decided cumulative action, acting much slower than digitalis, and being much more persistent after the heart has once been brought under its influence.

From these conclusions, and from a close study of a number of clinical observations made by a great many observers, Dr. Beyer does not seem to take sides with those who deem the drug indicated in all kinds of cardiac disease without exception, as, for instance, Prof. Sée would have it, nor with those who would, on the other hand, have it condemned entirely. He thinks that we possess in convallaria a very powerful cardiac remedy, and that the uncertainty, lack of uniformity, and inconstancy in the results hitherto obtained by clinicians is mainly owing to the fact that the morbid conditions under which convallaria might be used with advantage or disadvantage are not yet thoroughly understood. From its decidedly destructive action on the muscular substance, Dr. Beyer concludes that it is certainly and decidedly counterindicated in very far advanced cases of cardiac disease of whatever nature, and also in cases in which the muscular substance of the heart has undergone degeneration or suffered any material structural change from long and exhausting disease. On account of the cumulative action of the drug, he recommends that only one or two full medicinal doses should be administered during the twenty-four hours, and that preference should be given to the administration of convallarimin rather than to any other of its preparations.

WASHINGTON.

(*From our Special Correspondent.*)

THE GARFIELD MEMORIAL HOSPITAL opens this week, June 18th, for the reception of patients. It is located on the corner of Boundary and Tenth Streets, in the extreme northern portion of the city. Dr. H. M. Cutts is resident physician.

PITTSBURG.

(*From our Special Correspondent.*)

PROFESSIONAL FEES IN PITTSBURG.—A little over a year ago, Dr. R. S. Sutton performed enterotomy on a lady of this city. He removed four inches of the small intestine, united the ends by suture, and left the intestine in the cavity of the abdomen. The lady recovered and is still living. Her husband was reported to be wealthy. Dr. Sutton charged a thousand dollars for the operation and twenty-two days' attendance. He refused to pay, and Dr. Sutton brought suit. The action closed before the jury on the 28th of April, and they returned a verdict for three hundred and thirty dollars for the services rendered. Some of the learned jury, we are informed, thought that ten dollars would be a fair price for the operation, and one of them thought that as he had once paid a doctor thirty dollars for an operation, that this sum would be about right. They each put down the amount they would allow, and divided the aggregate sum by twelve, and fixed that amount as the verdict.

HEIDELBERG.

(*From our Special Correspondent.*)

HEIDELBERG SURGERY.—The methods of surgery fluctuate with time, with the conceptions of the operator, and with new discoveries. The surgery at Heidelberg is, probably, typical, and represents the best methods of German surgery. It is conducted by Prof. Czerny, who was the assistant of Billroth, of Vienna, some dozen years ago. He operates and lectures at the same time for an hour and a half daily. He will operate some days for four or five hours.

Heidelberg and its surroundings produce an incredible number of patients. Club-foot, diseased joints, cancer, lupus, and tumors constitute the bulk of the surgery. He often operates for ovariotomy. In club-foot, he seldom performs tenotomy, but forcibly straightens the foot, and retains its position by means of a plaster-of-Paris bandage. Much plastic surgery is done, *e. g.*, covering erosion from lupus or epithelioma, or building a nose, by removing healthy integument from the forehead. The results are excellent, and sloughing is rare. Almost absolute cleanliness and disinfection are the remarkable features of the clinic. The German who exclaimed at the International Congress, "Mein Gott, Listerism is todt," did not strike the truth. Disinfection is practised in every department in detail, *e. g.*, in the resection of the elbow-joint, the part is well soaped and

shaved, and washed with a one to three per cent. carbolic solution; then, Prof. Czerny, with well-disinfected hands and instruments, cuts down on each condyle of the humerus, removes the dead bone, washes out the wound with bichloride of mercury solution (1–2 to 1000), and sews it up; then he introduces some bone drainage-tubes, packed round with gauze holding powdered iodoform; this is put up in bags of wood-wool, disinfected with carbolic or bichloride solution; the whole is then bound with disinfected bandages. The joint is then put to rest, and not disturbed for ten days, unless pain, bleeding, or fever indicates it. Infrequent dressing is a strong feature of his clinic. In major operations—ovariotomy, large joint-openings, etc., he uses the spray. The therapeutic measures employed are, essentially, cleanliness, carbolic acid and bichloride disinfecting solutions, quinine in large doses, and the liberal use of powdered iodoform. His results are naturally very good, as he attends religiously to the minute details of all neatness.

Prof. Czerny is a man about forty-five years of age, with dark hair and broad shoulders. He has an energetic twinkle in his eyes, and is genial and good-humored. He is a demonstrative instructor, a man who talks to the point, and an original operator. His fame rests mainly on successful and original abdominal surgery. He is very kind and instructive to foreign doctors, and speaks good English.

THE INTERNATIONAL MEDICAL CONGRESS. — The Organizing Committee of the International Medical Congress, to be held at Copenhagen, August 10th to 16th, have just issued a pamphlet containing the rules and programme.

The Congress will be held under the patronage of H. M. the King of Denmark. Prof. P. L. Panum is President and Prof. C. Lange Secretary-General of the Organizing Committee.

The Congress will be formally opened on Sunday, August 10th, and will end on Saturday, August 16th. The work of the Congress will be divided into fourteen Sections, which will meet daily, from 10 A. M. to 12 M., and from 1 P. M. to 3 P. M. The general meetings of the Congress will be held daily, from 4 P. M. to 5.30 P. M. The official languages of the Congress are French, German, and English.

The following addresses will be delivered in the general meetings: On Metaplasia, by Prof. Virchow, of Berlin. On Morbific Microörganisms and Vaccinia Matters, by Prof. Pasteur, of Paris. International Collective Investigation of Disease, by Sir William Gull, Bart., of London. The Natural Production of Malaria and the Means for Making the Malarial Countries more Healthy, by Prof. Tommasi Crudeli, of Rome. The Neoplastic Diathesis, by Prof. Verneuil, of Paris. On Investigations of Food Rations for Men in Health and Disease, especially in Hospitals, Infirmaries, and Prisons, by Prof. Panum, of Copenhagen.

The Sections are as follows: 1, Anatomy; 2, Physiology; 3, Pathology; 4, Medicine; 5, Surgery; 6, Obstetrics and Gynecology; 7, Ophthalmology; 8, Pediatrics; 9, Dermatology and Syphilis; 10, Psychiatry and Nervous Diseases; 11, Laryngology; 12, Otology; 13, State Medicine; 14, Military Medicine.

Among the more important papers to be read we notice the following:

On the Morphological and Physiological Variability of Pathogenic Bacteria, by Dr. R. Koch, of Berlin. On a Uniform Nomenclature of Auscultatory Sounds in the Diagnosis of Diseases of the Chest, by Prof. Austin Flint, of New York. On the Antipyretic Treatment of Acute Infectious Diseases, by Prof. Liebermeister, of Tübingen. On the Antiseptic Treatment of Acute Infectious Diseases, by Prof. Bouchard, of Paris. The Etiology, Diagnosis, Prognosis, and Treatment of Tuberculosis, as Influenced by Recent Experiences in Pathological Anatomy and Experimental Pathology, by Prof. Ewald, of Berlin. Operative Opening of Pulmonary Cavities, by Dr. Edw. Bull, of Christiana. Is Acute Pneumonia an Infectious Disease? by Prof. Jürgensen, of Tübingen. The Most Important Methods of Antiseptic Treatment of Wounds, by Prof. Lister, of London; Prof. Mosetig-Moorhof, of Vienna; M. Schede, of Hamburg; Prof. Paul Bert, of Paris; Prof. Esmarch, of Kiel. Resection of the Stomach and Intestinal Tube, by Prof. Gussenbauer, of Prague. Trephining in Localized Diseases of the Brain, by Dr. Lucas-Championnière, of Paris; Prof. Ferrier, of London; and Prof. Mollière, of Lyons. The Treatment of Strictures of the Œsophagus, by Prof. Studsgaard, of Copenhagen. Antiseptics in Laparotomy, by Prof. Mikulicz, of Cracow. Oöphorectomy as a Remedy Against Nervous and Mental Sufferings, by Prof. Hegar, of Freiburg. Vaginal Excision of the Cancerous Uterus, by Prof. Schroeder, of Berlin. On the Operative Treatment of Extrauterine Pregnancy, by Prof. Litzmann, of Kiel. Cæsarean Section and its Modifications, by Prof. P. Müller, of Berne. The Treatment of Syphilis with Mercurial Injections, by Dr. Liebreich, of Berlin; Prof. Lewin, of Berlin; Prof. Neumann, of Vienna; and Dr. Martineau, of Paris. The Prognostic Significance of the Severe Local Manifestations Observed in Tuberculosis of the Larynx, by Dr. Solis-Cohen, of Philadelphia. Treatment of Goitre, by Dr. Morell Mackenzie, of London. The Operative Removal of Foreign Bodies and Pseudoplasms from the Air-passages, by Prof. Voltolini, of Breslau, and Dr. Geo. M. Lefferts, of New York. The Singing Voice: *a*. Its Proper Method of Training, by Dr. F. H. Bosworth, of New York; *b*. Its Cultivation Facilitated by Photography of the Larynx, by Dr. Lennox Browne, of London. The Antiseptic Treatment of Wounds in Time of War, with Particular Regard to the Employment of Safe, Efficacious, and Simple Requisites, as to Adapt them Particularly for Military Surgery, by Prof. Esmarch, of Kiel; Sir Wm. MacCormac, of London; Dr. Neudörfer, of Vienna; and Dr. Strube, of Berlin.

THE SAMUEL D. GROSS PROFESSORSHIP OF PATHOLOGICAL ANATOMY.—At a meeting of the medical profession of Philadelphia, held June 9, Drs. D. Hayes Agnew, Samuel Ashhurst, W. B. Atkinson, Roberts Bartholow, J. M. Barton, J. Solis-Cohen, J. M. Da Costa, R. J. Dunglison, Nathan L. Hatfield, I. Minis Hays, P. J. Horwitz, Wm. Hunt, Joseph Leidy, R. J. Levis, J. Ewing Mears, S. Weir Mitchell, G. R. Morehouse, Andrew Nebinger, M. B. Musser, Theophilus Parvin, W. H. Parish, Wm. Pepper, Wm. Thomson, Laurence Turnbull, W. S. W. Ruschenberger, H. H. Smith, Alfred

Stillé, Wm. H. Walker, and James C. Wilson, were appointed a committee to issue the following appeal:

"American surgery has had no better exponent than Samuel D. Gross, none so honored abroad and at home by institutions of learning, none more revered by his associates and his pupils.

"His long and brilliant professorial career deserves the perpetuation of his name in close association with medical tuition.

"In furtherance of this object the Alumni Association of Jefferson Medical College has inaugurated a movement to secure in some medical school the endowment of a *memorial professorship*, to be designated 'THE S. D. GROSS PROFESSORSHIP OF PATHOLOGICAL ANATOMY.'

"The profession at large, the personal friends of the late Professor Gross, and others interested in the advancement of medical education, are cordially invited to participate in this graceful recognition of conduct and services which have largely helped to establish the high standard of excellence to which surgery has attained throughout the United States, and to dignify the repute of American medicine."

Contributions may be sent to Dr. R. J. Dunglison, Lock-box 1274, P. O. Philadelphia, and will be acknowledged in the columns of THE MEDICAL NEWS.

D. Hayes Agnew, M.D., Chairman.

THE ILLINOIS MEDICAL PRACTICE ACT.—Recent decisions in two cases, one under the Act to Regulate the Practice of Medicine in Illinois, the other under the Dental Surgery Act, sustain the right of the Board of Health to determine the status both of a college and of a practitioner. Under the latter Act, the Supreme Court refused the petition of Isaac N. Sheppard for a writ of mandamus to compel the State Board of Dental Examiners to issue him a certificate or license, based upon a diploma of the Indiana Dental College. The Board refused the license, on the ground that the college was not a "reputable" institution.

It was argued that the law constitutes the Board judges of the standing of a college, and that there is no power of review vested in any other body. "If the Board should arbitrarily or unreasonably abuse their discretion, and refuse a license without any reason therefor, there is a remedy for such abuse of a discretionary power." But there was no ground for claiming that this was the case in the present instance. The Board, in its judgment, had decided that the curriculum of study and the requirements for graduation of the Indiana Dental College were not such as to entitle it to be classed as a "reputable dental college;" and there is no power in the law given to any person or body to review and set aside, or confirm the exercise of the discretion by the Board. The petition for a mandamus was denied.

In the case of the State Board of Health against C. Buel Rice, of Cincinnati, a graduate of the Medical College of Fort Wayne, tried in the Sangamon County Court, the defence set up the plea that, being a graduate of a "legally chartered medical society in good standing," the defendant was entitled to the certificate of the Board; and that it was not competent for the Board to inquire into the moral or professional character of such graduates. On the part of the prosecution it was shown that charges had been presented to the Board, alleging that Rice was in the employ of, and associated with, the "K. and K. Surgeons," a firm of advertising quacks, and that in various ways connected therewith his conduct was unprofessional and dishonorable, within the meaning and intent of the Medical Practice Act. Upon these charges the Board had refused to issue Rice a certificate until he had disproved the same. Instead of making any attempt at such disproof, Rice continued to practise, whereupon he was arrested for practising without the necessary certificate. The facts were admitted by the defence, but, as already stated, the court was asked to dismiss the suit on the ground that it was obligatory on the Board to issue its certificate to the possessor of a genuine diploma of any "legally chartered medical institution in good standing," regardless of the moral or professional status of the individual. This the court declined to do, but found the defendant guilty, and assessed a penalty of fifty dollars fine, and costs.

MEDICAL COLLEGE OF OHIO.—The Faculty of the Medical College of Ohio has decided to hold a preliminary examination of all candidates for admission to the lecture classes, in the absence of a diploma or other evidence of sufficient literary training. A chair of hygiene has also been added.

YELLOW FEVER VACCINATIONS.—DR. DOMINGO FREIRE, of Rio Janeiro, the discoverer of the so-called microbe of yellow fever, writes to the New York *Evening Telegram*. "I still continue the vaccinations: four hundred and six persons have been already inoculated without the slightest disadvantage. Yellow fever is now raging here in Rio. As soon as it is over I will write, giving the results respecting those vaccinated. For the present I can only say that the exemption is confirmed. In about two months I hope to be able to publish a full report of all my researches in regard to yellow fever."

MR. LAWSON TAIT, we are informed, intends visiting this country during this summer. He will sail for New York on August 9th, and on August 25th, he will deliver an address on Abdominal Surgery, before the Canada Medical Association at its meeting in Montreal.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 10 TO JUNE 16, 1884.

MIDDLETON, PASSMORE, *Captain and Assistant Surgeon.*—Leave of absence extended three months on surgeon's certificate of disability.—*Par. 3, S. O. 134, A. G. O.*, June 10, 1884.

BARNETT, RICHARDS, *Captain and Assistant Surgeon.*—Assigned to duty as Post Surgeon, Mount Vernon Barracks, Ala.—*Par. 2, S. O. 113, Headquarters Department of the East*, June 9, 1884.

GARDNER, EDWIN F., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Walla Walla, Washington Territory, and assigned to duty as Post Surgeon, Fort Canby, Washington Territory.—*Par. 1, S. O. 75, Headquarters Department of Columbia*, June 3, 1884.

PORTER, J. Y., *Captain and Assistant Surgeon.*—From Fort Ringgold, Texas, to Fort Brown, Texas, as Post Surgeon.—*S. O. 73, Headquarters Department of Texas*, June 9, 1884.

MADDOX, T. J. C., *First Lieutenant and Assistant Surgeon.*—From Fort Clark, Texas, to Fort Ringgold, Texas, as Post Surgeon.—*S. O. 73, Headquarters Department of Texas*, June 9, 1884.

BLACK, C. S. *First Lieutenant and Assistant Surgeon.*—From Fort Concho, Texas, to Fort Clark, Texas.—*S. O. 73, Headquarters Department of Texas*, June 9, 1884.

ORIGINAL LECTURES.

A CASE OF SUPPOSED PROGRESSIVE PERNICIOUS ANÆMIA.

An Abstract of a Clinical Lecture delivered in the Philadelphia Hospital.

BY EDWARD T. BRUEN, M.D.,

DEMONSTRATOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

GENTLEMEN: The history of this case is as follows: Mary L., æt. 47, has been from her youth subject to irregular menstruation and menorrhagia, and yet until three years ago she never suffered from any marked attack of illness. At that time she was admitted to the Episcopal Hospital to be treated for a metrorrhagia, and she partially recovered after six months' treatment. Her health, however, continued to decline, and a year ago she had presumably an attack of malarial fever, from which she convalesced, but her general health failing, she was admitted to this hospital during last fall. It is proper to add that she has led a fast life, and a specific taint may be suspected, though it cannot be established. Her condition has not materially changed since her admission, and with these data I commenced the investigation of her case February 1st, when I assumed the care of the wards. It is obvious that intense anæmia is present. The tongue, the mucous membrane, and the skin, all present an extremely blanched appearance, the latter is also of a yellowish hue. Digestion is impaired, and the motions of the bowels irregular. Physical diagnosis reveals that the splenic dulness is increased, the spleen measuring four inches transversely, by five in the vertical direction. Over the heart there is a bruit which, upon the usual inferential reasons, is probably functional or hæmic. The examination of the retina is negative. A diagnosis in this case can be most certainly reached by exclusion. The enlarged spleen, the blanched appearance of the patient, and the progressive character of the symptoms suggest leucocythæmia, but since the disease has existed for three years, the possibility of an incipient splenic leucocythæmia antedating a leucocytal excess, cannot be entertained. In leucocythæmia enumeration by the hæmacytometer should show not only the white corpuscles increased, but the red corpuscles diminished. Usually when the disease is established the proportion of white to red is greater than 1 to 20. For example, instead of 500,000 red corpuscles per cubic millimetre, there may be only half so many or less; and the white may be increased from 15,000, the normal average, up to several hundred thousand per cubic millimetre. The red corpuscles are usually normal in appearance, sometimes unduly pale; the leucocytes are often both larger and smaller than normal, and reagents develop several nuclei. No such increase has been found in this case, consequently further investigation must be made.

Hodgkin's disease is a process which may be defined as a more or less widely spread enlargement of the lymphatic glands, accompanied frequently by enlargement of the spleen and by progressive anæmia. The pathological feature of this process, viz., the lymphatic hyperplasia, is absent, so this disease must be laid aside.

The question of progressive pernicious anæmia in this case has been one of deep interest to me, and is my reason for bringing the case before you. The pathology of this disease is obscure, lesions in the medullæ of the bones, the spleen, and the supra-renal capsules, have been described, but its course is indicated by the terms pernicious, malignant, progressive, idiopathic.

The blood lesion in this case has been studied for me by Dr. Wm. E. Hughes, Medical Registrar of the University Hospital, with the hæmacytometer with the following report: "600,000 red and 3000 white corpuscles to the cubic millimetre. That is, the red are reduced to about one-ninth of their normal number, while the white are very slightly decreased, less than one-half. The red corpuscles are, most of them, larger than normal, some as large as white corpuscles; a few of them are very small. They are well colored, but some are tailed and otherwise irregularly shaped. The white are probably a trifle increased in size." This appearance of the blood is believed to accord with the lesions of this tissue in pernicious anæmia. In an idiopathic anæmia the appearance of the red corpuscles would not be so ill-shaped; they would be paler than normal, and also smaller. The exact changes of the blood in what may be termed symptomatic anæmia, such as in malaria, syphilis, tuberculosis, or albumenoid disease, etc., cannot be said to be positively established. Dr. Hughes, in his note, observes that in his experience in malarial anæmia the number of red cells is above 1,500,000, and the white not less than 50,000. Syphilitic anæmia would present the same characteristics as malarial anæmia with respect to red cells, but the white would be about 5000 in the cubic millimetre. Dr. Hughes has examined the blood from a large number of cases, and his observations are entitled to attention.

I believe, however, that deductions from physical signs should be made only after an analysis of the sum of the clinical history and the symptoms. The malarial element must be excluded from this case because the attack occurred only a year since, and the symptoms of this patient antedate this time. The syphilitic hypothesis is also insufficient because there are not distinct evidences of syphilitic lesions in the past or present history of the case. The circumstance that this patient always suffered from irregular menstruation and hemorrhages at the monthly periods, is of consequence, and it seems to me that she may suffer from a form of anæmia allied to the chlorotic. In other words, the depreciation of the patient's nervous vitality united to the history of menorrhagia has exercised a specially depreciating influence upon the blood-making function, which has resulted in a reduced elaboration of the corpuscular elements of the blood. It is, however, possible that the malaria has acted as an accelerating causative

complication, and perhaps this attack of malaria may account for the enlargement of the spleen.

With the above views, viz.: that in this case the excessive blood destruction depends upon insufficient activity of the blood-making functions in the economy, the line of treatment should be purely alterative and stimulant to the nutritive functions, and also tend to supply the essential elements of nutrition.

As an alterative, I believe no remedy will prove more signally useful than the continued use of mercury in some form. Small doses of bichloride of mercury, ranging between the $\frac{1}{50}$th and the $\frac{1}{100}$th of a grain, so that without salivation the stimulant influence of this drug as an alterative tonic may be kept up. Small doses of calomel, $\frac{1}{50}$th to $\frac{1}{100}$th of a grain, are sometimes equally useful. This treatment must be maintained for many weeks, or even months, but after a six weeks' course of the mercurial, iron, which previously may not have produced any good effect, can be used with advantage. While using the mercurial I shall order small doses of Fowler's solution at meal-time, and the mercurial in the intervals, three times daily. Occasional laxatives or digestive stimulants, such as strychnine or pepsine, form suitable adjuvants to this plan of treatment. To supply the essential elements of nutrition I shall order a liniment, composed as follows:

℞.—Lin. Saponis,
Ol. Morrhuæ, ... āā ℥vi.—M.

A tablespoonful or more shall be rubbed into the thighs and abdomen night and morning.

Much careful thought should be bestowed on diet. I shall recommend the Gluten Food, prepared by the American Health Food Company, and Murdock's Liquid Beef, as especially useful.

NOTE (March 28, 1884).—At this date the patient's health is obviously improved. There is a tinge of red around the lips and tongue, and the strength is increased. Dr. Hughes reports that the examination of the blood showed 1,305,000 red corpuscles, which is a very decided improvement on the condition when first examined. The size and shape of the corpuscles, however, are very little changed, most of them being larger than normal, and many of them still irregularly shaped.

REMOVAL OF FOREIGN BODIES FROM THE AUDITORY CANAL.

BY H. B. HEMENWAY, A.M., M.D.,
OF KALAMAZOO, MICH.

ABOUT four years ago, one Monday morning, I met an old acquaintance and successful surgeon at the depot of a small village in Illinois. He asked me if I could meet him that morning, to assist him in a small, but bothersome, case. He gave me the following history. I made no records of the case, except in my mind, and, hence, must relate the events from memory.

The evening before (Sunday), Mrs. T., the wife of a lake captain, brought her little boy, about five years old, to the office of Dr. B., to have him remove "something from his ear." She said he had been playing that afternoon with the other children. In his play, he got à "lemon-stone" into his ear, and could not get it out. It gave him but little pain, but affected his hearing. Upon examination, the doctor could easily see the stone, not very far back, probably at the most contracted portion of the canal. He placed the child's head on one side, and tried to dislodge the stone by jarring. It did not come. He still regarded it as a simple case, and took his forceps; but, in trying to get hold of the stone, he pushed it further in. Then, though several times he seemed to have a good hold, the stone would always slip from his grasp just as he thought it was coming out. He tried the use of wire and silk snares, but with the same result. He tried to hold it by tenacula, but could not. He worked until his patience was about used up, if his patient was not, and the ear was in a worse condition than when he began. He then told the mother to take the boy home, and he would come around the next morning, and give him chloroform. He explained that he could see better in the daytime, and that the pain in the ear was so great that the little fellow would resist his efforts, unless he should be under the influence of an anæsthetic.

Meanwhile, the doctor endeavored to invent some new method to try. He searched his books for some suggestion, but to no purpose. After his relation of the above history, remembering a hint which my old professor of anatomy, Dr. R. L. Rea, had given us as to the shape of the auditory canal, I asked the doctor if he had tried an ear-spoon. He replied "no;" he had none, and if he had, he could not see how that would help the matter very much. I explained the *rationale*, and offered the spoon from my pocket-case.

We found the patient in a very good condition. There was considerable inflammatory action, and, hence, sensitiveness and pain in the auditory canal. With the spoon, we could feel the stone, and found it now impacted, the swelling of the tissues helping to keep it firmly in place. Equal parts of chloroform and ether were given. After working some time, without making any progress, the doctor was about ready to give up the attempt, when I managed to turn the stone over. Slowly, but surely, we then drew it along the canal. My ear-spoon is of the common style—ear-spoon and groove-director combined. After the stone was turned, our chief trouble lay not so much in the slipping of the spoon from the stone, as in the fact that we could not get a firm enough hold on the spoon with our fingers. We need a cross-bar or loops for the fingers on the handle. When, finally, we brought the stone to the concha, we found that it was not a lemon-seed, but a cherry-stone.

I have given the history of this case thus fully, for it well illustrates how much trouble one may have with a very simple matter. With an ear-spoon in the first place, Dr. B. could easily have removed the stone in a few minutes, but, after the swelling took place, it was very difficult.

What is the *rationale* of the removal of foreign bodies from the auditory canal? The canal extends from the concha, inwards, forwards, and downwards,

being slightly bent, the convexity of the curve being upwards and backwards. The canal has its smallest diameter near its centre. A cross-section of the canal shows it to be ovoidal in shape, the longest diameter being vertical, except at the inner end, where it is nearly horizontal. The foreign body is likely to lodge in the contracted portion of the canal. The use of forceps (which, with a general practitioner, is the first instrument tried in such cases) is almost sure to push the body back beyond the constriction, and thereby increase the difficulty. If used at all, the operator must remember that there is more room above and below than at the side of the foreign body. An ear-spoon, however, can almost always be passed *over* the body far enough to get a good hold. The spoon is so shaped that it takes very little more room than the foreign body, when applied like the blade of the obstetric forceps. When the body lies against the membrana tympani, remember that there is more room in front, or behind, than above the body. It is better to pass the spoon behind the body; for, if passed in front, the pressure upon the body would tend to push it through the membrana tympani. On account of the shape of the canal, too, the foreign body is more likely to lie against the anterior than the posterior wall of the canal. Inasmuch as the surgeon will want his instrument above the foreign body, when it nears the contracted portion of the passage, it will generally be best to pass it neither directly over, nor exactly behind, but above and behind the object to be removed. In this position, on account of the relation of the parts, the tip of the spoon will simply be passed along the wall of the canal and the membrana tympani, until in position for traction. In the case related above, the instrument was easily passed into position, and but for the partly macerated and badly swollen condition of the parts, extraction would not have been very difficult. It was the most difficult case of the kind I have ever seen, and well illustrates the fact that a surgeon had better leave a case entirely alone, unless he is fully prepared to treat it.

Other modes of extraction. Forceps may do very well for many cases, but in those in which the doctor is the most perplexed, they generally avail but little. Of course, the foreign-body forceps of the aural surgeon are to be preferred to any other form; but few general practitioners possess such an instrument, and even if they did, in many cases it would be found useless. A snare oftentimes may be of great assistance; but it is very difficult to make it stay on a hard, smooth, round body like a cherry-stone. The syringe will frequently remove objects that have not passed the constricted portion, and may assist in the removal of small objects from the vicinity of the membrana. When used upon a large object that is located beyond the constriction, and which nearly fills the canal, it only macerates the tissues.

While in other modes of manipulation, the position of the head is important, it is especially so in the use of the syringe. With the head of the patient thrown a little back and toward the affected side, if the operator, pulling the pinna auris upward, and a little backward, throws a *gentle, steady* stream of *lukewarm* water along the superior wall of the canal, the momentum of the current reflected from the membrana tympani against the mass, together with the action of gravity, will quickly accomplish the desired result, if this method will succeed at all. Much force must not be used.

A little hot wax or glue on the end of a stick has been recommended, if the body has not passed the constriction. It seems to me that this is to be condemned as being less efficient and more dangerous than any of the other methods. In some cases, the foreign body may be dissected and removed in pieces. If, however, the object is as hard as a cherry-stone, it would probably be less harmful to leave it in than to attempt to break it. In a few cases, a tenaculum may be used, but care must be taken that harm be not done by its slipping.

SEROUS CYSTIC TUMORS OF THE ORBIT.[1]

BY L. WEBSTER FOX, M.D.,
OPHTHALMIC AND AURAL SURGEON TO THE GERMANTOWN HOSPITAL; CLINICAL ASSISTANT, EYE DEPARTMENT, JEFFERSON MEDICAL COLLEGE HOSPITAL.

IN vol. xii. No. 2, *Archives of Ophthalmology*, Dr. J. L. Thompson described one case of cystic tumor of the orbit, removed by electrolysis. I wish to place on record four cases treated by a different method, resulting in permanent relief.

CASE I.—W. M., aged eighteen years, consulted me relative to a small growth projecting from the left upper eyelid, situated below the orbital ridge to the nasal side. Vision, both eyes $= \frac{20}{L}$; refraction myopic. No lesion in fundus oculi. Mobility of eye not interfered with. The elevation was round, glistening, and translucent; the skin over it quite thin, somewhat tense; it had attained the size of an almond. As its contour could be changed by manipulation, I suspected a sac filled with fluid, which was confirmed by making an examination with an exploring needle. The fluid escaping was clear yellowish, of about the consistency of honey. The tumor was detected when the patient was five years of age.

CASE II.—Miss B., aged fifteen years, a well-developed girl, was brought to me in October, 1881, by her mother, with the following history: When the patient was six years old the mother detected a small, soft growth, about the size of a pea, under the skin of the right upper eyelid, nasal side. The family physician was consulted. He advised non-surgical interference at this time. The tumor has slowly increased in size; barely discernible to an observer's eye, but distinctly felt by fingers. There has been no pain. The exploring needle revealed fluid. No lesion in fundus oculi. Vision, both eyes $= \frac{20}{XX}$. Family history irrelevant.

CASE III.—James C., aged twenty-four years. At the age of ten years, a small tumor was noticed below the nasal end of the eyebrow, about the size of a bean. The patient was seen by me, for the first

[1] Read before the Philadelphia Ophthalmic and Aural Book Club Association, February 18, 1884.

time, in April, 1882. The tumor at this time was about the size of a shellbark, buried in the tissues of the orbit, displacing slightly the inner third of the ciliary margin of the upper eyelid, but not interfering with the movements of the eyeball—hence no diplopia. In October, 1881, the tumor was opened by a surgeon, nothing escaping but an oily fluid. The tumor collapsed; the wound was dressed and healed rapidly. In about two months the cyst had regained its former size and remained so till the patient presented himself to me. The exploring needle proved the presence of fluid. Vision, both eyes $= \frac{20}{XX}$. No lesion in fundus oculi.

CASE IV.—On April 23, 1883, my friends Drs. Miller and Wirgman asked me to examine with them a case with the following history and conditions. H. G. B., aged twenty-six years, a patient of Dr. Miller. At the age of three years, a small tumor, about the size of a split-pea, was detected below the orbital ridge on the nasal side, buried in the tissues of the right upper eyelid. The tumor was of slow growth, for at the time of the operation, twenty-thsee years after its discovery, it had only attained the size of an almond. The tumor, upon digital examination, fluctuated; an exploring needle proved the presence of fluid; no lesion in fundus oculi, and the vision in both eyes was normal. The patient suffered no pain nor inconvenience. The tumor was removed by Dr. Wirgman to relieve the patient from the apprehension that a serious trouble might develop.

Dr. Miller recently informed me that the operation has been successful, as there is no evidence of the cyst returning.

The external appearances of the tumors were strikingly similar. The integument covering had a glistening, pink color, slightly translucent, moderately tense, and not adherent to the tumor. The sizes of the cysts vary; they are not pointed, but oval, in shape, having their greatest breadth immediately below the skin, while the small or pointed diameter lies buried deep in the orbit. Their point of development, apparently, is from the periosteum covering the nasal bone, finding their way to the surface, expanding where there is least constriction from the tissues, are of exceedingly slow growth, never interfering with the mobility of the eyeball nor movements of eyelid. These cysts are detected in early life, and, no doubt, like the dermoid, are developed in the embryonic period. The cyst-walls, which are thin, fibrinous, and elastic, cannot be easily dissected from the adjoining tissues.

The fluid contents of the sac are clear-yellowish, and of the consistency of honey. Microscopic examination revealed an oily fluid filled with fatty, granular masses, large oval cells, similar to mucous cells; no cholesterine crystals, or dermoid *débris*.

Treatment.—The application of irritants externally, puncturing the cyst, injecting dilute tincture of iodine, signally fail to give permanent relief. An incision of not less than six lines was made with a sharp-pointed bistoury, or Beer's knife, into the sac, making the wound in the horizontal direction, and the contents of the tumor emptied by gentle pressure. A point of nitrate of silver was then thoroughly applied to the inner walls of the cyst (great care must be observed to apply the caustic to the lower part of the cavity); by this procedure the inner walls are destroyed, thereby creating two inflamed surfaces which become agglutinated, and the cyst is obliterated. A small pellet of lint is usually kept in the external orifice of the wound for three or four days, to prevent closure, as the destroyed tissues will slough, and a slight discharge make its appearance. For the first six hours after the operation cold dressings are applied; after this, boroglyceride. There is no reaction, the cavity healing rapidly.

1306 WALNUT STREET, PHILA.

MEDICAL PROGRESS.

CORROSIVE SUBLIMATE AND IODOFORM IN THE PUERPERAL STATE.—Valuable information is obtainable from the report of the discussion (in the Fifty-sixth Congress of German Physicians and Naturalists) on Kehrer's paper on "Sublimate Injections" (*Archiv für Gynäkol.*, Bd. xxii., Heft 1). Mercuric chloride is shown to be odorless, and cheaper and more soluble than carbolic acid. Küstner, who obtained the uterine secretions by means of tubes direct from the interior of the womb, discovered that the micrococci, which normally abound in them, disappeared promptly after sublimate injections, but only slowly after carbolized injections. Bardeleben's experiments seem to show that a solution of 1 in 10,000 is sufficiently energetic. Ehrendorfer contributes an important paper, "Ueber die Verwendung der Iodoformstäbchen." He recommends iodoform pencils containing ninety to one hundred and fifty grains of pulverized iodoform, and fifteen grains each of gum-arabic, glycerine, and pure starch, which are easily soluble and flexible; they are thus readily introduced into the uterine cavity, after the genital tract has been irrigated with an antiseptic lotion. The iodoform was only used as an intrauterine pencil in labors which were abnormal, or which were followed by purulent endometritis, etc. He reports in detail twenty-nine cases, nearly all severe, in several of which the patient's condition was rendered desperate by the existence of gangrene, erysipelas, and other serious complications. König has shown that iodoform intoxication is rare when not more than ten grammes (about one hundred and fifty grains) of pure iodoform are applied.—*Medical Times and Gazette*, May 31, 1884.

ACTION OF PAPAYOTIN.—ROSSBACH, in the course of recent studies on this subject, finds that the juice of papaya, and papayotin and papain, can be given internally, by direct intravenous injection and by hypodermatic injection. He also finds that the drug may be used in cutaneous eruptions, for cancerous nodules of the skin, for the removal of diphtheritic membranes, to assist meat-digestion in the stomach and intestines, in dyspepsia and other diseases of the digestive organs, in cancer of the stomach, and for intestinal worms, which papayotin should kill.—*Deutsche med. Wochenschrift*, April 3, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

SATURDAY, JUNE 28, 1884.

INTERMITTENT CHYLURIA.

AN interesting discussion, which took place at the Berlin Medical Society, on this still obscure subject, is published in the *Berliner klin. Wochenschr.* for March 10. PROF. SIGMUND reported an example which elicited the views of VIRCHOW, SENATOR, EWALD, and LITTEN.

The case was that of a German who, excepting a year spent in France during the recent war, had never been out of the fatherland. At the siege of Paris, he had dysentery for two weeks. At the beginning of 1883, he became weak and restless, sweated profusely, and complained of rheumatic pains in the back and thighs, and in the lower part of the abdomen and testicles. His urine was albuminous, and remained turbid after the albumen was separated. The turbidity was found to be due to molecular fat, of which there was 1.038 per cent. present. A power of 900 diameters revealed neither animal nor vegetable organism in the fresh urine. This fatty urine alternated with perfectly normal fluid, quite free from albumen and fat, the longest time during which the urine was free from chyle being seventy-two hours. It was present on an average once in every twenty-four hours, and appeared most frequently between 2.15 and 7.45 A.M. The condition gradually improved, but had not disappeared altogether.

As to the cause of the chyluria, Sigmund thought it could not be due to any disease of the kidneys, or that these organs could even play an intermediate *rôle*. He thought rather that a mechanical defect existed, as the result of which the two streams of urine and chyle commingled somewhere between the pelvis of the kidney and the beginning of the urethra. This view is confirmed by a case reported by Havelburg, and is accepted also by Hoppe-Seyler. It explains the sudden occurrence, but not the intermission in the case reported, for this was found quite independent of the recumbent position, whether in natural sleep at night, or that during the day induced by chloral. While admitting that the cause of the disease had not yet been ascertained, he thought that chyluria, as it prevailed in the tropics and in temperate climes, are not one and the same thing.

Senator had recently met with a case of chyluria, also intermittent, in which a study of the blood by day and at night discovered no parasite, nor did the blood exhibit a fatty character, while it contained, in addition to albumen, hemialbumose, but no peptone, which had been found by Brieger and others, and no sugar. He thought, however, that in his case the phenomenon was influenced by rest and action.

Ewald thought the intermittent occurrence might be explained by the existence of a valvular fistula, which would be kept closed by a sufficient intralymphatic pressure, but which became patulous when such pressure was diminished.

Litten had observed intermittent chyluria in a case of intermittent fever, but had been unable to establish any relation between the chyluria and the pyrexia or apyrexia. The patient averred that he had had both conditions for a long time.

Virchow thought that the fact that the phenomenon appeared in the morning was in direct opposition to the explanation of Ewald and that it was difficult to follow the path the chyle must pursue in reaching the bladder. If the condition is one primary to the lymph vessels, the current must travel backwards, which is contrary to all experience — the absorbed chyle travelling toward the root of the mesentery and receptaculum chyli. On the other hand, the absence of sugar is the more remarkable, since in the analogous phenomenon—elephantiasis lymphorrhagica—sugar is present. One cannot but believe that in the latter condition the chyle passes through the blood to the periphery, and from the blood is passed into the lymph vessels; in a word, that a chylous state of the blood must precede the separation of the chyle. The case is different with chylous ascites. Here we must have an overdistention of the chyle vessels of the intestine and their rupture into the peritoneal sac. In the neighborhood of the pancreas, we also often have an ectasy of the lymph vessels, with colossal cyst formation. Prof. Virchow thought that further observations should be made, and especially that the blood should be examined at different times, with a view to determining the quantity of fat therein.

Senator considered that the experiments of Brieger, by which it was shown that the liberal ingestion of

fat by the patient produced no change in the urine, and especially none in its quantity, were opposed to the view of Ewald.

Ewald thought he had been misunderstood by both Virchow and Senator. He did not claim that the appearance of the chyle in the urine was the result of an increase of chyle in the chyle vessels after digestion, but rather to the opposite condition, such as occurs during fasting, whereby a fistulous communication between the lymph vessels and urinary passages is opened, which is closed by a distended state of these same vessels, just as in certain cases of pneumothorax the opening in the lungs is closed if the pressure within the chest is great, while it is open if the pressure diminishes.

It is scarcely likely that four men could have been found better qualified to explain the phenomena of chyluria, especially as it occurs in temperate climes, than those whose views have just been presented. Yet it is evident that nothing definite was added to our knowledge, although ingenious hypotheses were suggested.

It is almost certain that Sigmund is correct in his explanation as to one mode in which chyluria may occur; for we ourselves know of one instance of chylous hydrocele occurring in the practice of Dr. W. H. Mastin, of Mobile, Ala., in which the weeping lymphatic was actually exposed in a dissection,—appearing as a papular swelling, from the apex of which the lymph was observed to exude. Ligation of the papule was followed by a cure of the condition, whereas simple tapping previous to this operation had been ineffectual in preventing reaccumulation. The portion excised was sent to us for examination, and a cavernous lymphatic structure was easily demonstrated. That Ewald's suggestion would satisfactorily account for the intermittent character of the flow is also true, but difficult to prove, and until proof is adduced, it must be regarded as speculation, and not fact.

MYOCARDITIS.

J. Wickham Legg's "Bradshawe Lecture" on "Cardiac Aneurism," for 1883, and W. H. Welch's paper on the "Pathology of Myocarditis," read at the meeting of the American Medical Association, in May last, indicate a revival of interest in the subject of the non-valvular affections of the heart. These investigations, like others which, since the days of Corvisart, have been from time to time carried on in the same field, are wholly within the domain of pathology. When contrasted with the importance of this group of cardiac lesions, the amount of clinical work brought to their study is surprisingly small, and the results are still more insignificant. It is true that much attention has been bestowed both from the pathological and the clinical standpoint upon fatty heart, the acute parenchymatous degenerations of fever and phosphorous poisoning, and the loss of tone in the heart-muscle which accompanies general debility. Without undervaluing the importance of these conditions, we do not hesitate to say that infrequency of occurrence, gravity of symptoms, and as an immediate cause of death, myocarditis, in its various forms, constitutes an affection not less worthy of attention.

Within recent years Rigal and Jubel-Renoy, in France, and L. M. Petrone, in Italy, have sought to clear up the symptomatology of myocarditis and to establish rules for its diagnosis. But the clinical papers upon this subject may be counted upon the fingers of one hand, and in a majority of the works on diagnosis, myocarditis does not find place even in the index. The causes of this are not far to seek. During the last fifty years, clinicians have been engaged in elaborating and refining the art of auscultation, and in analyzing its signs until the diagnosis of those diseases of the heart which are characterized by coarse alterations in structure is an almost perfect procedure. Meanwhile, the recognition of affections not manifest by specific signs, but by feebly marked deviations from the normal, and by a vague or blurred symptomatology, has been overlooked. At the bedside myocarditis is practically an unknown disease. Even when its presence is suspected, there are, as yet, no means by which a definite diagnosis can be reached. Examinations ending in uncertain results have little attraction for the practical physician. Hence, the unfortunate neglect into which this disease has fallen. We do not believe that the resources of clinical medicine are unequal to the task of recognizing most of the forms of this disorder, or, indeed, to that of tracing out the obscurities of its etiology. We believe it to be simply an untilled field that is rich in promise. The results of laboratory work will accumulate until sufficient data for clinical study are at hand. To arrange, differentiate, exclude, and classify, are processes that await only the accumulation of facts and cases. Already, much has been accomplished. It is now known that neither endocarditis nor pericarditis is a necessary accompaniment of myocarditis.

Welch has found myocarditis in the examination of cases which may be clinically grouped as follows: *First*, when there is no symptom of heart disease. *Second*, sudden death without previous heart symptoms. *Third*, sudden death preceded by one or more attacks of angina pectoris. *Fourth*, after cardiac insufficiency of a few days' standing. *Fifth*, in cases of old heart disease. Jubel-Renoy regards the diagnosis of chronic myocarditis as having attained already some clinical exactitude. He arranges the diagnostic data into three groups: 1. Enfeeblement of the systole, and of the pulse,

with augmentation of the frequency and persistence of regularity. 2. Moderate hypertrophy, varying within considerable limits, which are determined by the amount of dilatation present. 3. The common absence of murmurs; occasionally the occurrence of a soft, systolic mitral murmur, often temporary. Then *bruits de galop*, tricuspid blurring, pulmonary congestion, often unilateral, all coming and going until asystolism, gradually developing, brings the scene to an end.

ALBUMEN OR ALBUMIN.

Albumen spelled with the vowel *e* in the last syllable has been used in the English language, probably for centuries, to indicate a nitrogenous principle which constitutes the chief part of the white of egg, and is found in the serum of the blood, chyle, synovia, serous fluids, etc., and sometimes also in the urine, generally as an abnormal constituent. It was evidently adopted directly from the Latin *albumen*, for white of egg. And the English adjectives, albuminous and albuminoid, have been properly spelled with an *i* in the third syllable, in accordance with the termination of the root, which is formed from the genitive *albuminis*. On the other hand, German writers, particularly physiological chemists and urinologists, have for some years spelled the noun with an *i*. Such is the spelling of Gorup-Besanez, of Hoppe-Seyler, Neubauer and Vogel, Hoffmann and Ultzmann, and others. But that this spelling is not the only one used by Germans is proved by consulting Lucas's Dictionary, German-English part, in which we find the word album*e*n, and album*i*n is not given.

Recently a few English-writing physiologists and urinologists, notably, Foster in his text-book of Physiology, have adopted the German orthography, which may also be said to be the French, although in that language the last syllable is *ine*. Dr. Millard, in his recent work on Bright's Disease, has also used this spelling, and in an article just published, expresses his surprise that English-writing physicians should continue to use the older style, but we think a careful examination of the history of the use of the word fails to justify his emphasis in the matter. The early German writers use the term *Eiweiss* so constantly for albumen that it appears to us not unlikely that albumin was a later introduction from the French, the terminal *e* of the last syllable being omitted. While we admit the desirability of uniformity, we do not see sufficient reason for English writers deviating from the original well-founded spelling of the word.

TUBERCLE BACILLI IN DEEP-SEATED TISSUES.

In some recent studies published in the *Wiener med. Wochenschr.*, March 29th, on tuberculosis, Weichselbaum took pains to look for the bacillus tuberculosis in tubercles most deep seated, and distant from the external air, including the inner membranes of the brain, the thyroid gland, the endocardium, the liver, the spleen, the kidneys, the peritoneum, and the omentum, and in none of these situations did he fail to find them. The number, it is true, varied greatly, and sometimes sections of nodules from the liver and spleen contained but one to three, while in other tubercles, especially the pia mater and peritoneum, including the omentum, the number was so great that even with a low power the places of their accumulation could be easily recognized.

These observations are important, in comparison with those of Formad. Weichselbaum found that with the onset of caseation the number of bacilli diminished materially, and they were confined more and more to the periphrey, or to the giant cells. According to Formad, on the other hand, bacilli are more numerous when the tubercle begins to soften.

Weichselbaum also ascribes the failure of many observers to recognize bacilli, to imperfect staining, of imperfect optical appliances, or to inexperience. He considers an Abbe's illuminator and an oil immersion system essential.

TRANSMISSION OF TUBERCULOSIS.

The presence of bacilli of tuberculosis in the blood, in chronic tuberculosis, has a bearing upon hereditary transmission of tuberculosis, and also upon its spread by vaccination. For if a bacillus can reach the innermost tissues of the economy, why may it not travel also from the blood of the mother to that of the embryo? Why, too, may it not be transferred with the vaccine lymph. The possibility of either event dare not be denied, if Koch's views be acknowledged. At the same time, even admitting such possibility, it is plain that the chances of such an accident are so few, that we need not be influenced in our practice as to vaccination; while natural difficulties in the way of transmission from the blood of the mother to that of the embryo account for the frequency with which the children of tubercular parents escape the malady.

In like manner, it is a legitimate result of these facts, that it is not venereal disease alone which may be communicated from the male to the female in coitus. The man with tuberculosis of the seminal vesicles and urethra may inoculate the woman with whom he has intercourse, and thus produce a tuberculosis of the uterus and Fallopian tubes. Weichselbaum tells us of a case of tuberculosis of the seminal vesicles and urethra, in which the number of bacilli was enormous. A seminal fluid in such cases would naturally be loaded with bacilli, which, carried up

into the cavity of the uterus, might plant themselves in such favorable nidus as happens to be present. It is fortunate, in view of these facts, that tuberculosis of the genital apparatus of the male is as rare as it is, else we would find such mode of transmission more frequent. In the meantime it behooves practical physicians to bear these views in mind and apply to them the test of experience and observation.

SOCIETY PROCEEDINGS.

AMERICAN NEUROLOGICAL ASSOCIATION.

Tenth Annual Meeting, held in New York, June 18, 19, and 20, 1884.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, JUNE 18TH—FIRST DAY.

AFTERNOON SESSION.

THE VICE-PRESIDENT, DR. WILLIAM J. MORTON, read a letter of regret from the President, Dr. Robert T. Edes, of Boston, who was unable to be present, and then offered a few remarks himself, in the course of which he made a defence of specialism, particularly in the field of neurology. The specialists in this department, he claimed, had contributed more to general medical and surgical knowledge than any other class of writers, and this, he thought, justified the neurologist in his subdivision of scientific labor. Neurology is but following the general tendency of the times, and with better right than many other specialties, for it offers to its followers a field for investigations so vast, so fruitful, so impossible of exhaustion, that even if they should desire it they are precluded from equally extended investigations into other branches of medicine. To the sick the subdivision of labor is an advantage, since, other things being equal, this means skilled labor. Clearly, this field for work is all that the neurologist can attend to—it is certainly more than the general practitioner can keep up with. Dr. Martin also gave a retrospective glance over the past work of the Association, and referred briefly to its present condition.

He then introduced the PRESIDENT-ELECT, DR. ISAAC OTT, of Easton, Penna., who delivered the *Annual Address*.

The special subject to which this was principally devoted was a consideration of

THE PATHS OF THE VARIOUS FIBRES IN THE SPINAL CORD.

He said that it was now about seventy years since Charles Bell announced that the anterior roots of the spinal nerves were motor and the posterior sensory. Since then countless experiments had been made, and there had been a gradual increase in the knowledge of the physiology of the cord, which was due principally to improvements in technique. He said that he knew of no more deceptive thing than to assert the extent of disease of the spinal cord without a careful microscopic examination. In regard to the paths of coördination, there had been various opinions up to 1840, when Longet made numerous experiments upon the subject, and announced, as the conclusion, that the anterior columns of the cord were motor and the posterior ones sensory. Prof. Schiff's idea of the spinal cord was that the posterior columns conducted tactile impressions, that the gray matter conducted in all directions afferent impulses which gave rise to affections of general sensibility and such afferent impulses as were concerned in reflex action. Dr. Ott then mentioned various views to show that the facts put forth were greatly in need of correction. After alluding to the experiments and remarks of Finch, Ludwig, Schiff, and others, he said that the observations of Ludwig proved that in the lumbar cord of the rabbit sensory and motor fibres ran in the lateral columns. Afterwards, with the assistance of Dr. R. Smith, he had himself proved the same statement to be true for the cervical segment of the spinal cord of the rabbit. To these experiments the objection was rightly urged that the animal was not permitted to live for a considerable time after the operation. But experiments of his own on kittens which sustained these injuries for several weeks proved that, in addition to the lateral columns, the anterior columns contained voluntary motor fibres. He then referred to a number of experiments on dogs by other observers, and remarked that only one recent authority still defended the theory that the motor and sensory fibres did not lie mainly in the lateral columns. All the later experiments went to show, he said, that the lateral columns are the principal conductors of sensation and motion, that the gray matter does not directly participate, that the anterior columns conduct voluntary motion. In regard to the posterior columns, he could substantiate Prof. Schiff's assertion that, after bleeding a rabbit and dividing the whole cord except the posterior columns, impressions of touch are conveyed by the posterior columns. In conclusion, he said that he should also like to state that decussation of fibres in the central nervous system is quite extensive, that the motor, sensory, vaso-motor, sudorific, and inhibitory (the two latter running in the lateral columns) are over each other.

AN EXHIBITION OF PREPARATIONS

was then made by DR. BURT G. WILDER, of Ithaca. The first one illustrated the *existence and circumscription of the portæ (foramina of Monro) in the adult human brain*, and he said that he was moved to present it, first, because he was not aware that any just such preparation had previously been made; and, secondly, because Mr. Duval had contended that the foramina of Monro did not exist at all in the adult human brain. He then described the manner in which the brain exhibited had been prepared. It was kept in the dura mater, and having been suspended by threads in a, at first, weak solution of alcohol, the infundibulum was removed, and, by means of a canula, alcohol at a temperature nearly of freezing was forced through the arteries for about ten days, by which process it was thoroughly hardened. The specimen plainly demonstrated to the eye the dorsal boundary of the foramen of Monro.

The second preparation exhibited was a portion of the brain of an infant at birth, hardened in the same manner, which showed distinctly *the presence of the crista fornicis*. This feature seemed to be always present in the brain of the cat, as he had examined the brains of hundreds of these animals, and had never as yet found it absent. In the human subject, however, it

disappeared as the child grew older; and, so far as he knew, it had never been observed in the adult. It was presumable that in all mammalian brains it existed at some period of life.

He had of late discovered two additional cases of *absence of the corpus callosum in the domestic cat;* but had, unfortunately, neglected to bring the specimens with him. The number of instances in which he had now found this wanting seemed to indicate that if brains were more frequently examined with proper care this anomaly would be found not to be so rare as had heretofore been generally supposed.

The last specimen which he exhibited showed the *covering of the cerebellum by the cerebrum in a young chimpanzee* whose brain was hardened within the skull. It was one which illustrated very well the necessity of making such preparations with great care. When the orbital lobe was made horizontal, the tip of the occipital lobe was seen to project about a millimetre beyond the cerebellum.

DR. AMIDON then exhibited a *human brain in which the corpus callosum was absent,* and said that he would read the history of the case at a future session.

DR. E. C. SPITZKA remarked that as one proceeded from the lower to the higher orders of animals the cerebrum and cerebellum both became more intricate, and that in the lower monkeys the overlap was much greater than in the chimpanzee and other anthropoid species.

A REPORT FROM THE COUNCIL

was presented, recommending the election of certain new members to the Association, but, as a quorum had not been present at this meeting of the Council, the report was, on motion, laid on the table.

The Association then proceeded to the nomination and

ELECTION OF OFFICERS

for next year, which resulted as follows:

President.—Dr. Burt G. Wilder, of Ithaca, N. Y.

Vice-President.—Dr. Leonard Weber, of New York.

Secretary and Treasurer.—Dr. G. M. Hammond, of New York.

Councillors.—Drs. W. R. Birdsall and W. J. Morton, of New York.

Evening Session.

ELECTION OF NEW MEMBERS.

A report of the Council was read by the Secretary, recommending for membership in the Association Dr. G. Betton Massey, of Philadelphia, and Drs. George W. Jacoby and Sarah J. McNutt, of New York; and these candidates were then duly elected by ballot.

THE REPORT OF THE COMMITTEE ON THE HAMMOND PRIZE ESSAY OF THE AMERICAN NEUROLOGICAL ASSOCIATION

was then read. The subject proposed for the prize essay was, *The Functions of the Optic Thalamus in Man.* Only one essay had been received; but this was a very elaborate thesis, written in German. After giving a minute analysis of its contents, the report stated that it possessed great merit and constituted a valuable contribution to scientific literature, but that it hardly met the requirements demanded in a prize essay on the subject in question, since it treated the functions of the thalamus in a too restricted way, while the part of it relating to the human physiology was scanty and inconclusive. The prize, therefore, was withheld for the present year.

In the discussion which followed the reading of the report of the committee, the opinion was quite generally expressed that the prize ought to have been awarded to the essay described, and the matter was, therefore, on motion of Dr. Wilder, referred back to the committee for further consideration.

DR. BURT G. WILDER, of Ithaca, N.Y., read a paper on

MACROSCOPIC ENCEPHALIC NOMENCLATURE.

His idea was to simplify names in use as much as possible and render them more flexible. There are two sets of terms recommended; the one applicable to toponomy and the other to encephalic organomity. Having alluded to one or two other modes of subdividing the brain, he mentioned that it could be divided into a series of five segments, the principal parts of which were the medulla, cerebellum with the pons, the optic thalami, and the cerebrum (the olefactory lobes being a division of the last). He proposed to take up the different parts of the brain in categories, and separate the heterogenous mass of terms which was now so cumbersome. The technical names which he proposed were brief and composed each of a single word, and monomial technical nomenclature possessed the following advantages: (1) brevity, (2) flexibility, (3) adaptability, (4) capacity for uniform abbreviation. In speaking of the flexibility, he remarked that the names could readily be turned into adjectives. Thus, it was hardly admissible to make an adjective of dura mater or pia mater; but there was no difficulty whatever about the terms dural and pial. The adaptability of the nomenclature was shown by the fact that any single word might be adopted into any language based on the Roman alphabet. Professor Wilder then referred to a list which he had made out for the use of students and others. In it single words took the place of compound ones, as for instance, dura and pia, instead of dura mater and pia mater, alba for white matter, calcar for hippocampus minor, hypocampa for hippocampus major, callosum for corpus callosum, cineria for gray matter, porta for foramen of Monro, and thalamus for thalamus opticus. Then, there are certain abbreviations which are somewhat of the character of nicknames, such as proen. for proencephalon (cerebrum), dien. for diencephalon, epon. for eponcephalon, mesen. for mesencephalon, and meten. or metencephalon ("medulla" as far as the pons). Instead of the Latin word ventriculus (English, ventricle) he uses the Greek κοιλια (English, cele). The ventriculi lateralis thus became the procœlia or procele (first and second ventricles, together with the aula and portæ); the third ventricle, the diacele; the fourth ventricle (its cephalic part), the epicele; the caudal portion of the fourth ventricle, the metacele; and the aquæductus Sylvii, or iter a tertio ad quartum ventriculum, the mesocele.

On motion of Dr. Amidon, the discussion of Dr. Wilder's paper was postponed until the following day.

DR. A. D. ROCKWELL, of New York, read a paper on

A CASE OF TONIC SPASM OF THE DIAPHRAGM (?).

The case had been under observation for a long time, and was believed to be unique in character. For this

reason and because its pathology was so obscure he presented it in the hope that light might be thrown upon it by some of the members of the Association. The patient was a lady, 35 years of age, and the mother of four children, who first began to suffer from the present trouble twelve years ago. The paroxysms which caused her so much distress were substantially the same both in kind and severity then as now, but their recurrence had been marked by uncertain and varying intervals. Before the present year they seldom occurred more than once a year, and sometimes two and three years intervened between the attacks. During the months of April and May past, however, the attacks had been very frequent. For some time they continued every day, and occasionally twice a day; so that her strength was fast becoming exhausted. Formerly no special hour marked the occurrence of the paroxysms; but latterly they had occurred in the morning between the hours of five and seven. They were described as follows: The patient is awakened out of a sound sleep by a vague feeling of pressure and distress, which soon develops into the symptoms now to be described. The pain, or rather distress (for there is nothing about it that even simulates anything of a neuralgic type), is felt about the lower end of the sternum and over the epigastrium, and extends to a corresponding point in the back. It is as if a crushing weight were being applied—as if the front and back were being pulled together. So sure is the patient in her own mind of these subjective phenomena that she has always declared that they could be caused by nothing else than a spasmodic contraction. The recumbent position is impossible; and so she moves about the room partially bent, or leans forward against any support, with short and gasping inspirations, pallid countenance, and with agony depicted in every feature, until the paroxysm subsides, or until the anguish becomes unendurable, and necessitates the administration of an anæsthetic. The pulse becomes weaker and somewhat less frequent, but is not at all irregular. The attack lasts from twenty minutes to three-quarters of an hour, and after passing away leaves the patient much prostrated. From this, however, she quickly rallies; but a bruised and sore feeling remains for many hours.

On one occasion, about two years ago, she awoke in the night with the paroxysm, which culminated so rapidly that before the chloroform, which was immediately resorted to, could take effect, she became quite pulseless and apparently lifeless; and it was only on pushing the anæsthetic that the pulse became stronger and the inspiration apparent. Several repeated administrations of the chloroform were necessary before the attack was finally broken up. For several years, as these paroxysms, were so unfrequent, and the general health continued good, chloroform was almost the only remedy employed, hypodermatic injections of morphia having been found insufficient to cause relief. When they began to occur frequently, however, many efforts were made to prevent their recurrence. Electricity was tried in all its forms, together with a varied internal treatment; but without avail; and it was not until he resorted in despair to the use of the actual cautery that the attacks seemed to be at all controlled. To his great relief, none had occurred since its application, nearly a month before; and, what was also a great source of relief to him, the general health and strength had markedly improved with the rest thus afforded.

That this was a case of spasm of the diaphragm the patient, who was not altogether devoid of anatomical knowledge, was firmly convinced. Having referred to other possible hypotheses in regard to the trouble, such as biliary calculus, disorder of the heart and malaria, and shown them to be untenable, Dr. Rockwell stated that, after years of observation in this particular case, he was himself quite convinced that the symptoms were due to a spasmodic contraction of the diaphragm, notwithstanding the absence of certain objective symptoms, such as expansion and immobility of the lower half of the chest, projection of the epigastrium and closure of the œsophagus, that he had found emphasized in print and speech. In connection with the apparent efficacy of the actual cautery, he referred to a paper which he read some years ago before one of the New York societies, on the use of the galvanocautery, one of the cases reported in which was kindred to and as unique as the one now related. The patient was suffering from a supposed organic stricture of the œsophagus. In consultation with the late Dr. Willard Parker, it was demonstrated that the obstruction to the passage of food was due to spasmodic contraction, excited by the introduction of anything into the tube. This condition had been persistent for several months, and the patient was slowly dying of inanition. Every spasm was associated with severe pain in the dorsal region of the spine. After the examination revealed the true character of the disorder, the actual cautery was applied along the spine over the seat of the pain, and resulted in immediate and permanent relief of the spasm, the patient thereafter being able to swallow solid food without the slightest difficulty.

DR. DANA inquired what reason Dr. Rockwell had for excluding angina pectoris, which was sometimes characterized by much the same symptoms as those described in this case; to which he replied that the seat of distress was so low down and so limited (the pain not being transmitted upward at all) that it had not occurred to him that the trouble might be angina. He had seen a number of cases of the latter affection, and the symptoms had been so different from those met with in this instance, that it did not seem possible to him that the disorder could be of that nature.

DR. BIRDSALL inquired whether he was entirely satisfied that two affections could be excluded, viz., hysteria and hepatic calculus, either of which might possibly offer an explanation of the phenomena noted; to which Dr. Rockwell replied that he was perfectly satisfied in his own mind that the trouble could not be hysteria, but that the matter of hepatic caculus he had not taken into consideration.

DR. DANA then said that it seemed to him a physical impossibility that the diaphragm should be in a state of tonic spasm without the abdominal walls being either tense or protuberant. One could not make any experiment with reference to the diaphragm, either in his own person or in others, without exciting such a condition of the latter. As well might we expect contraction of the biceps without the flexing of the forearm. The ability to swallow, especially solid food, would also seem to exclude spasm of the diaphragm.

DR. ROCKWELL remarked that he would like very much to know precisely what the trouble was in this case. Spasm of the diaphragm had seemed to him to offer the most satisfactory explanation of the symptoms; but that he was not by any means positive in this diagnosis was shown by the fact that he placed an interrogation point after the above designation in the title of the paper. As he had mentioned in his report of the case, there were certain points which seemed to militate strongly against the hypothesis of diaphragmatic spasm, according to the views generally accepted in regard to that rare affection; but it had occurred to him that there might perhaps be possible a slighter form of spasm of the diaphragm, in which the phenomena referred to were either absent or else developed to but a small extent. As regards the matter of deglutition, the patient had always been able to swallow a little whiskey during the paroxysms when the effort was made (which he thought would be possible even if the œsophagus was pressed upon in some degree), but she had never attempted to take any solid food.

DR. SPITZKA said he thought that the absence of protrusion of the abdominal walls during the paroxysms might perhaps be compensated for by a general expansion of the thorax; but Dr. Rockwell stated that he had never noticed that there was any such expansion. The only external phenomenon that he had observed was a slight fluttering appearance over the epigastrium. Dr. S. G. Webber having inquired where the cautery was applied, he stated that it was applied all along the spine, from the neck to the waist.

THURSDAY, JUNE 19TH—SECOND DAY.

AFTERNOON SESSION.

DR. WM. A. HAMMOND, of New York, explained that he thought the committee on

THE PRIZE ESSAY

were perfectly justified in excluding the thesis that had been presented to them, notwithstanding its very great merit, on the ground that it contained very little original research in regard to the functions of the optic thalamus in man (which was the point that was regarded essential in order to secure the prize).

On motion of DR. WILDER the minutes were amended by the striking out of so much of the motion which he had made at the previous session as referred the matter of the prize essay back to the committee for further consideration.

ELECTION OF MEMBERS.

The Council reported that they had unanimously recommend for associate membership, Dr. Danillo, of St. Petersburg, whose name was proposed by Dr. Wm. J. Morton. At a later session he was duly elected, and Dr. J. Leonard Corning, of New York, was elected an active member.

The discussion of Professor Wilder's paper on

ENCEPHALIC NOMENCLATURE

was then declared in order.

DR. WILDER begged leave to present a portion of his manuscript which, owing to the lateness of the hour, he had omitted to read at the preceding session. He said he desired to offer, as a basis for discussion, the three principal arguments which had been urged against the adoption of the nomenclature which he proposed. The first of these was that some of the terms now in use were *indicative*. This, he acknowledged, was a strong point, and in certain instances it was unanswerable. At the same time, by using a single short word for a long compound name the difficulties of encephalic nomenclature would be rendered much less perplexing, as, for instance, the adoption of the simple word *iter* for the *iter a tertio ad quartum ventriculum*. In this way the term *biceps* had already been adopted into the vernacular. All the names of the new nomenclature could be learned in a week's time, and if their acquisition were attained gradually by the student, no effort would be required in the matter. Such a short and simple word as *lenum*, he certainly thought, was preferable to a long and high-sounding term like *torcular Herophili*. The second argument was, that some of the old designations were commemorative, as the *foramen of Monro* and the *fissure of Sylvius*; but as many of them were altogether unjust, he did not think the objection had much weight. The third was, that most of the present terms were familiar; but this seemed to him a puerile argument, which applied with equal force to almost every advance in the scientific world. The proposed nomenclature might necessitate a little effort on the part of those already familiar with anatomical terms; but the beginner would be able to learn the new names much more quickly than the old. In conclusion, Dr. Wilder read the following resolutions, which, he said, would in due time be presented for the consideration of the Association:

Resolved, That in the opinion of this Association the advancement and dissemination of an accurate knowledge of the macroscopic anatomy of the brain will be facilitated by substituting for many of the polynomial terms, technical and vernacular, now in use, technical names which are brief and consist each of a single word.

Resolved, That we recognize the advantages of using such monomial compound terms as antiplexus, diatela, mesocœlia, hemiseptum, præcommissura, medipedunculus, postcornu, and cognate words proposed by Professor B. G. Wilder, and see no serious objection thereto.

Resolved, That there be appointed by the Chair a committee of five on macroscopic encephalic nomenclature, with instructions to report at the next meeting a list of such terms as, in their judgment, may properly be recommended for use.

DR. DANA said that he had taken a great deal of interest in Professor Wilder's work of reform, and the matter had appealed to him all the more forcibly as a teacher himself. He begged leave, however, to offer a few criticisms that had occurred to him. Many of the points advocated by Dr. Wilder, he thought, were admirable, and he had no doubt that they would eventually be adopted. But, on the whole, it seemed to him that Dr. Wilder took too much the position of an anatomist and of an anatomical teacher. It was desirable to have terms that medical students could acquire readily; and this, he thought, was not the case with many of the proposed names. Dr. Wilder seemed inclined to sacrifice too much for the sake of brevity, and the adoption of such abbreviations as *dien.* for diencephalon, and *meson.* for mesencephalon, he considered entirely unjustifiable and

unnecessary. There was no harm in giving the full word, which conveyed some meaning to the student, and therefore assisted him in the acquisition of the technical terms. As well might we adopt a series of arbitrary words from the Chinese or Japanese as such "nicknames" as these. Dr. Wilder also showed a strong tendency to increase the already large number of anatomical landmarks in the brain, and thus render the matter more complicated, instead of simplifying it.

Thus, he thought, there was no necessity for the introduction of the term *ripa* (defined by Dr. Wilder as the line formed by the rupture of the endyma along the lines of its reflection from the entocœlion surfaces) to describe a little artificial part of the brain. He thought it would be much better, therefore, if he would devote his energies to reducing the number of terms already in use, instead of manufacturing new ones. He believed, too, that he made a mistake in endeavoring to substitute new words for some of the old ones which were universally received and understood, and which there was no necessity whatever for changing; as, for instance, *alba*, for white matter, and *mesocele*, for the aqueduct of Sylvius. His idea seemed, simply, to get a monosyllable instead of a polysyllable in many instances. He objected also to the substitution of *κοιλια*, or *cœlia*, for ventricle, and to the formation of adverbs by the termination *ad*. Finally, he considered it a bold thing for one man to attempt to revolutionize an entire nomenclature; and thought that if Professor Wilder was really desirous of having his views adopted, he ought to submit them to an international commission, rather than to try to secure this end single-handed. At the same time he wished fully to recognize the great value of the services which he had already rendered in the direction of facilitating the study of the brain.

DR. BIRDSALL thought that the Association ought to be proud to subscribe to the admirable system devised by Professor Wilder, whose researches had reflected so much honor upon it. The only valid objections that could be urged against it, he believed, were in reference to certain details of terms, and he himself strongly objected to the nicknaming of scientific words. If the word meant anything it should be retained as a whole, provided it was not too cumbrous. In writing, it was often desirable to make use of abbreviations, but there was no necessity for employing them in speaking. Dr. Dana's objection that Prof. Wilder wished to multiply rather than reduce the names, he thought was not a sound one; for while there were many little points about the brain which had already received names, but were of no practical significance whatever, so far as known, there were others which were of essential use, especially to the comparative anatomist, which had not as yet been designated by special terms. As to whether the object desired by Prof. Wilder could not be secured by himself or by the action of societies was, he thought, an open question; especially when it was remembered what had been accomplished by such men as Orne and Huxley. Single individuals might make up consistent nomenclatures, and he thought Prof. Wilder showed a very generous spirit in expressing his willingness to submit the results of his labors to the judgment of a committee, as he had proposed to do. He had one suggestion to make, and that was, that if the committee arrived at any conclusion in regard to this matter, it should invite the coöperation of learned bodies in Europe, so that, if any changes were thought desirable, their adoption might be the more readily secured throughout the scientific world. This kind of work was more of an international character.

DR. WILDER remarked that in his resolutions he had carefully excluded all reference to those abbreviated terms which seemed to excite the most opposition. In regard to his nomenclature in general, he would say, that if those present were as familiar with some of the other anatomists as they were with Quain and Gray, they would find that he had in reality originated very few of the terms employed.

On motion of Dr. Wm. A. Hammond, the consideration of the resolutions read by Dr. Wilder was postponed until the session of the following day.

DR. G. M. HAMMOND, of New York, then read a paper on the subject,

CAN LOCOMOTOR ATAXIA BE CURED?

He said that, as time had passed, reports of cases of this affection cured had come before the profession, many of them made by men of such undoubted learning and high reputation that we could not afford to overlook them. The question, therefore, that arose was, Are these true cases of ataxia, or is there some other morbid condition of the spinal cord which, when present, gives rise to symptoms similar in every respect to those resulting from sclerosis of the posterior columns?

He had collected a few cases of undoubted cure of what was supposed to be locomotor ataxia, and he thought that their histories and the different methods of treatment employed went far to settle the question of the curability of posterior spinal sclerosis.

Case I.—The patient, whom, he said, he was fortunately able to present before the Association for the second time, was the subject of a short paper which he read last year. He then exhibited him as a case of locomotor ataxia cured, and he was happy to say that the cure had so far stood the test of time. Having related the history in detail, Dr. Hammond stated that when the patient came under his care he applied the actual cautery several times to the spine, together with dry cups, the ether spray, and static and galvanic electricity. From this time the patient began to improve until complete recovery, with return of the tendon reflex, ensued. On this latter point he had him tested by several members of the Association at the meeting in June last, and he had had no treatment whatever since then.

Case II.—Reported by Desplot (of Lille) in *L'Union Médicale*, Nov. 29, 1883. Patient 54 years of age. Had contracted syphilis twenty years previously. Symptoms of locomotor ataxia of five years' standing. Treated with Gibert's syrup and mercurial frictions. In five days an amelioration of the symptoms, and in five months a complete cure.

Case III.—Under the care of Dr. Wm. A. Hammond. Two years ago presented all the symptoms of locomotor ataxia. A specific history admitted. Treated with iodide of potassium and bichloride of mercury, alternating occasionally with nitrate of silver. The actual cautery was also applied to the spine, as well as dry cups, the ether spray, and galvanism. A complete cure gradually resulted, though there had been no return of the tendon reflex.

Case IV.—Reported by Schultz, of Heidelburg, in 1881. Patient, who was 48 years old, first seen in April, 1871. Had had symptoms of locomotor ataxia for a year, and had constantly been growing worse. Marked improvement followed the use of the galvanic current, and in two years he was considered completely cured. Several years afterwards he died suddenly during an attack of acute intoxication, up to the time of the latter having continued perfectly well (with completely restored tendon reflex on both sides), with the exception of slight eneuresis both at night and through the day. At the autopsy, however, diffuse degeneration of the posterior columns in the lumbar region was found, together with degeneration of the outer division of the posterior columns of the dorsal region and slight degeneration in the column of Goll. In such a case, Dr. Hammond thought, we were forced to conclude that some other condition of the cord, coexisting with or occurring separately from the sclerosis, was capable of producing a majority, if not all, of the symptoms of ataxia; and that this morbid state, under certain conditions, was capable of being removed by appropriate treatment. In support of this view, he quoted the following cases:

Case V.—Characteristic case of ataxia reported by Desnos. The patient died, and the autopsy showed that there was intense congestion of the cord, but not the slightest evidence of sclerosis of the posterior columns, or, in fact, any part of the cord, could be discovered.

Case VI.—Also reported by Desnos. Patient 24 years old. Specific history. Prompt recovery under antisyphilitic treatment. Desnos regarded this, also, as a case of congestion.

Case VII.—Reported by Dr. Henry Lyman, in the *Chicago Medical Journal and Examiner* for January, 1883. Well-marked symptoms of ataxia. At first treated with ergot, nitrate of silver, and galvanism, but did not improve. Diagnosis of ataxia confirmed by Drs. Seguin and Beard, of New York. Then, after using iodide of potassium and bichloride of mercury for some time, in addition to the nitrate of silver, some of his friends advised him to try Junod's boot. This he used on both legs, besides dry cupping on both sides of the spine, and in two years from the time he was first seen he was found to have completely recovered, with the exception of some slight degree of ataxia in the movements of the feet. The tendon reflex, however, had not returned.

Having briefly called attention to a few of the most interesting points in connection with the more striking of the above cases, he said that from a study of them he had arrived at the following conclusions:

1st. That the absence of the patellar tendon reflex in locomotor ataxia is not always caused by sclerosis of the posterior columns.

2d. That sclerosis of the posterior columns may exist without being accompanied by the ordinary prominent symptoms of ataxia.

3d. That congestion of the posterior half of the spinal cord may give rise to most, if not all, of the symptoms of locomotor ataxia.

4th. That it is impossible during life to make a differential diagnosis between posterior spinal sclerosis and posterior spinal congestion.

5th. That posterior spinal congestion is curable.

6th. That there is no evidence to show that sclerosis once existing in the spinal cord has ever been removed.

7th. That those cases of so-called locomotor ataxia which have been cured are simply cases of spinal congestion, more profound in the posterior half of the cord.

DR. WILLIAM A. HAMMOND thought that the author of the paper was probably correct in his opinion in regard to congestion of the cord, and said that a case had lately come under his care which went to confirm the truth of this hypothesis. Just about a month ago he was consulted by an English weaver, residing in Newark, and a man of great intelligence. At that time he was suffering from all the symptoms of well-marked locomotor ataxia, the lancinating pains in the limbs being of excruciating severity. There was, apparently, a history of syphilis, but the man was not at all sure whether he had had syphilis or not. He was ordered the iodide of potassium in large doses; but there had been no improvement whatever at the end of two weeks, although he was at that time taking sixty grains of the iodide three times a day, in addition to one-thirtieth of a grain of the bichloride of mercury. He then gave him codeia (which Dr. Hammond had found to be the best remedy for the relief of the lancinating pains of locomotor ataxia), to insure sleep at night, and one-quarter of a grain of nitrate of silver three times a day. The improvement that followed was extraordinary, and two weeks afterward all the symptoms of ataxia had entirely disappeared. The tendon reflex, which had been lost, was not only restored, but was found to be exaggerated. He did not know how else to explain this case except on the hypothesis of congestion of the posterior columns extending to the lateral columns of the cord.

DR. ROBERTS BARTHOLOW agreed with the author that some cases of so-called locomotor ataxia could be cured; but, what kind of cases, said he, were they? Some years ago he had cured a case with the iodide of potassium, but it was caused by mercury; and he had no doubt that there were to be met with at present many cases of metallic poisoning the symptoms of which were perfectly typical of true ataxia. Having spoken of the cases due to syphilitic gummata, which, he said, could be cured by iodide of potassium, he referred to those due to chronic syphilis, in which there was a true sclerosis, in consequence of the constitutional effect of the disease, and said that a sharp distinction ought to be made between these two classes of cases. Furthermore, he wished to express his conviction that under the use of remedies which were now available, and to one of which he would presently call the attention of the Association, many cases of genuine locomotor ataxia could be arrested. It was true that lost parts and the *status in quo* could not be restored, but it was possible, at all events, to prevent the degenerative tissue-changes from progressing any further.

DR. J. LEONARD CORNING thought that the cases referred to by Dr. Hammond in his paper were convincing. The fact that the autopsy in a well-marked case of locomotor ataxia revealed nothing but congestion seemed to him very conclusive sort of evidence; evidence that could not but be accepted. The effects of fluctuations in the blood-supply inside the cranial vault were recognized, and he did not see why they

should not be also in regard to the cord, although the vascularity of the parts might not be so great. One practical point of importance was, he thought, that—granting that a hyperæmia was the starting-point of the affection—we could, by relieving this condition, arrest its further progress.

DR. G. M. HAMMOND stated that, being obliged to withdraw before the conclusion of the discussion, he wished to say a few words on the remarks that had already been made. He did not consider, he said, that the cases with symptoms resembling those of locomotor ataxia which depended on spinal congestion and metallic poisoning, were cases of true ataxia. The existence of sclerosis was essential to constitute this disease, and sclerosis, he was convinced, was never cured. As illustrating this point, he refetred again to Schultze's case, which had been described in his paper.

DR. S. G. WEBBER said that Dr. Hammond had reported his case as the first in which the tendon reflex had been known to return. Last year, however, he had himself reported two or three cases which had had all the symptoms of locomotor ataxia, and yet in which the tendon reflex was restored. One of these cases he did not suppose to be a genuine one of ataxia. The others were more evidently cases of ataxia, and one of them had entirely recovered. The patient had since died of a cardiac complication, but, although there was an autopsy, the spinal cord had not as yet been examined. Déjerine had found at the autopsy of a case supposed to be one of locomotor ataxia that the pathological condition was really multiple neuritis, and it therefore seemed probable that some of the cases in which cures were reported were of this nature, instead of being cases of ataxia. He should question, he said, whether hyperæmia of the columns of the cord could continue for weeks and months without giving rise to organic changes; and such a condition was, at all events, not yet proved.

DR. A. D. ROCKWELL remarked that, after all, the cases of locomotor ataxia, or supposed cases of the disease, in which a cure was reported were so few in comparison with the whole number of cases that they were really of very little significance. In looking over his notes, he found that he had treated forty-four cases of the affection. In the beginning, he thought that he had cured a number of cases, but he was now convinced that they were not genuine instances of ataxia. He also had read of one case of peripheral multiple neuritis which had been mistaken for this disease. In cases simulating locomotor ataxia, he thought that static electricity was of considerable benefit, and both Dr. Morton and he had reported cases cured by means of this agent.

DR. MASSEY said that he had seen one case cured. This was a gentleman who was a mountain climber, and who took no care whatever of his health. In 1866 he had syphilis. When he came under observation he had nearly all the symptoms of locomotor ataxia in its earlier stages. In addition, he suffered from profound melancholy. For one year he continued to grow worse, in spite of treatment, but he then began to improve, and when seen by Dr. Massey three years after this time, he was apparently perfectly well, though the tendon reflex had not been restored. For the first two weeks of his treatment he was placed on large doses of iodide of potassium, but this seemed to have a bad effect, instead of causing improvement. Afterwards the treatment consisted of the use of protoiodide of mercury, galvanism, and the application of the faradic brush to the spine.

DR. C. K. MILLS said that he had seen a number of cases of pseudo locomotor ataxia cured, but he had never yet seen a case of the regular type get well. By this he said he meant that type which was recognized pathologically as posterior spinal sclerosis. The solution of the cure of pseudo cases had already been referred to in the discussion, and among the kinds of cases which were susceptible of cure were those due to syphilitic gummata of the cord, to meningeal inflammation (sometimes involving also the periphery of the cord itself), and multiple neuritis. In regard to the latter, he stated his belief that this affection sometimes eventually resulted in locomotor ataxia. He also referred to neuralgic and hysterical cases, and said that a knowledge of having been exposed to the danger of syphilis sometimes gave rise to the latter. In such cases the tendon reflex was not absent, as a rule. Congestion of the spinal cord, he thought, might give rise to many of the symptoms of posterior spinal sclerosis; but it was his own impression, that one could rarely say that there was a localized congestion of certain parts of the cord, as the posterior columns, for instance. It seemed more probable to him that there was a condition of meningeal congestion and irritation, or possibly of actual inflammation of the meninges. The point upon which he wished to lay special stress was, that, after all, the regular typical form of locomotor ataxia, recognized as dependent on extensive sclerosis of the posterior region of the cord, was not curable.

DR. MASSEY remarked that the case which he had described was evidently a typical one in all its symptoms (including diminution of sexual power), except that the pains are not so severe as was frequently the case. The patient was excessively nervous, but a man not at all given to introspection, and he thought that there was no hysterical element in the case.

DR. BANNISTER, of Kankakee, Illinois, mentioned two cases, in which most of the characteristic symptoms of locomotor ataxia were present, but which he believed were in reality instances of myelitis. There were no autopsies, however, to confirm this opinion.

DR. BIRDSALL said that he had had one case which he might have reported cured if he had done so in time; but after about a year's interval new symptoms began to develop. The patient was a woman, who experienced great relief for eight or nine months under the use of galvanism, etc. Up to that time the characteristic Argyll-Robertson pupil had not developed; but within the last six months this had appeared, and, in addition, there was now commencing atrophy of the optic nerve. There had been an increase of pain, but now in a new area, the upper extremities. There had been no return, however, of the former ataxic symptoms, and the tendon reflex had been restored. Here, then, was a case which at the end of a year, and for six months afterward, could have been reported cured; and, as far as the ataxia was concerned, this was still the case. This seemed to be an irregular case, in which other parts besides the posterior columns (in all probability the lateral columns) were affected. Dr. Birdsall also mentioned another case which was cured, as far as

ataxia was concerned, although the patient's patellar tendon reflex was still abolished. It seemed to him that many of these cases could show a long interval of time before the upper part of the end became invaded, and during this interval of repose were liable to be reported as cured. On the other hand, he believed there were many functional cases, and that there were still others that were due to localized lesions involving the lateral columns. In regard to the matter of congestion, he thought this was a speculative point which could not be definitely pronounced upon at present; but he agreed with Dr. Webber, that it was difficult to accept the proposition that congestion could continue for an indefinite period without giving rise to organic changes.

DR. S. G. WEBBER, of Boston, then read a paper on

MULTIPLE NEURITIS.

Neuritis, he said, had lately assumed an importance which had not formerly been accorded to it, and it had only been within a very few years that a more general inflammation of the nerves had been recognized. Having given a *résumé* of the bibliography of the subject, he said that up to this time he had found records of six cases without autopsies and twelve with autopsies. He then proceeded to relate in minute detail, four cases which had been under his own care at the Boston City Hospital. One of these had been in a boy and the other three in women. One of the latter was almost moribund when admitted, and died the next day afterward; and another died seventeen days after admission, there being in this case various complicating affections. It was from this last patient that the specimens exhibited were taken, and numerous sections of the spinal cord, as well as of the nerves all over the body (nearly all of which were affected), were made. These cases, he thought, were sufficient to serve as examples. During the past autumn and winter there had been eighteen undoubted cases of multiple neuritis under treatment at the Boston City Hospital, and fourteen of them had been under his own observation. In addition, he had seen one case in private practice, and one other case in a child, in which the diagnosis was somewhat doubtful between neuritis and infantile paralysis. Of the nineteen undoubted cases, the youngest was nine years old, and the oldest fifty-one. More than half were between twenty and thirty years of age. An interval of from one week to four months elapsed in the different cases, between the beginning of the attack and admission to the hospital. The stay in the hospital varied from two days to six months, and, as a rule, the patients were not well at the end of four months after the trouble began. In five cases, taking cold was attributed as the cause of illness; but in the others there did not seem to be any assignable cause. Nine of the patients were females and ten males, and three deaths occurred among them.

Disturbance of sensation was one of the most constant and prominent symptoms, and the pain was described variously, as aching, burning, shooting, and boring. There was, as a rule, much hyperæsthesia of the skin, general tenderness over the muscles, and very marked tenderness along the tracts of nerve-trunks, which could often be readily traced by the sensitiveness of the parts. There was, at first, stiffness, and afterwards paralysis. The limbs became more or less contracted (being for the most part in a state of semi-flexion); and in some instances the contraction was extreme, the heels, for instance, being drawn up to the back of the thighs, and the knees nearly to the chest. Having dwelt for some time upon the condition of the various reflexes, which were not uniform (though the tendon reflexes were generally absent), he mentioned that the temperature and pulse were usually raised in the early stages, and in the two fatal cases this continued throughout the period when they were under observation. There was sometimes œdema of the limbs, and even of the face, and if there was also excessive smarting, as occurred in a number of instances, the disease was liable to be mistaken for rheumatic fever. The neuritis began most frequently in the legs. In fatal cases the disease made rapid progress.

Now that the peculiar symptoms of this affection had been clearly pointed out, the diagnosis was not difficult, except, perhaps, in slight cases. The diseases which it was most likely to be confounded with were, anterior poliomyelitis, spinal meningitis, locomotor ataxia, progressive muscular atrophy, lead paralysis, and acute rheumatism. Three or four of the cases mentioned, were supposed to be of rheumatic character when first admitted to the hospital.

In twenty patients suffering from the disease known in Japan as kak-ke, Scheube, who believed it to be due to a specific poison, had found neuritis in every case; and recently Dr. J. B. Lacerda had claimed to have discovered the bacillus of beri-beri. The nature of the pathological process in these cases was generally believed to be an inflammation of the nerves; but in September last, Erb had suggested (1) that it was possible and probable that purely functional disturbances of the trophic centres in the spinal cord produced anatomical disturbances (degenerative atrophy) in the periphery (the motor nerves and muscles); and (2) that it was possible that besides the complete destruction and separation of the trophic centres, yet other pathological processes occurred in them, which need not always go so far as to show themselves in the form of total degenerative atrophy of the peripheral regions of these centres. It had been shown, however, that Erb's hypothesis was less likely to be correct than that which referred the lesion to a peripheral neuritis. Having described the degenerative changes in the nerves as found in the case from which the sections were exhibited, and referred to the observations of Gombault, in rabbits, in which he had produced neuritis artificially, Dr. Webber said that, considering the changes found about the annular constrictions, it was reasonable to consider the disease as neuritis, not dependent upon changes in the spinal cord.

In most cases the patients recovered more or less completely, but recovery was very slow in severe cases; much time and patience being required to straighten the contracted limbs, and strength being regained very gradually. He was not sure, he said, that any treatment shortened the attack. Salicylic acid seemed to cut short the pain in some cases, and when it returned it was not quite so severe. It was necessary to give morphia to relieve pain. A four to five per cent. solution of carbolic acid applied on cloths to the painful limbs was of decided advantage. Ice to the spine felt grateful in one case, and hot water in another, while blisters over nerves seemed to be of advantage in one

or two instances, especially in a case in which the hyperæsthesia was very persistent. He thought it well to try to avoid or diminish the extent of the contraction by gentle extension or position of the limbs, a sandbag to rest the feet against, etc., as the contractions were difficult to overcome. To do so, required a persistent use of massage, extension, and electricity.

Dr. Rockwell said that in a case of his in which he made the diagnosis of multiple neuritis, what annoyed the patient most was burning sensations in the limbs. After trying various agents in vain for the relief of this, he finally stripped the patient naked, and touched the sensitive points all over the body with the actual cautery. He repeated this half a dozen times during the next six weeks, and it was followed by great relief. Whether this procedure had any ultimate effect on the course of the disease he could not say, as the case passed out of his notice.

Dr. Birdsall thought that Dr. Webber's contribution to this subject was one of great importance, as multiple neuritis was just beginning to be studied. He was not certain but what Erb was correct in his hypothesis that the affection was really dependent on cerebral changes; but this was a theory which no one could prove at the present time. It was certainly very interesting that such a group of cases as Dr. Webber had had the opportunity of studying should have occurred so nearly at the same time.

Dr. R. W. Amidon presented the brain taken from a patient suffering from *Word-deafness and Blindness, without Paralysis*, but omitted the reading of the case in order to permit Dr. Roberts Bartholow, of Philadelphia, to read a paper on

SOME USES OF THE CHLORIDE OF GOLD AND SODIUM IN NERVOUS AFFECTIONS.

Having stated that gold was mentioned in the *Anatomy of Melancholy* as a cure for that affection, and quoted the passage of the *Canterbury Tales* in which Chaucer says that "Gold in phisike is a cordial," he spoke of its use by the Arabian physicians in certain mental and nervous diseases; after which he referred to Trousseau's and Hahnemann's researches in regard to it. The homœopaths used it, he said, for the relief of hypochondriasis and of increased discharge of urine. Its principal effect was probably that of an alterant, or—as such agents are now more properly called—a promoter of tissue metamorphosis. It was of threefold service, he thought: *first*, as a general alterant; *second*, in nervous diseases; and, *third*, in genito-urinary diseases. The preparation which he himself preferred was the double chloride of gold and sodium, as this was readily diffusible, while the simple chloride of gold was diffusible to a very small extent. He used it in doses of one-twentieth of a grain, two or three times a day. It was a good tonic, and increased the number of red globules in the blood; but its chief effect was upon connective tissue. Hence, in pathological conditions in which the connective tissue was involved, it was likely to prove of service. In sclerosis of the posterior columns of the spinal cord, he did not claim that lost parts could be restored, but his experience with this remedy had been such as to convince him that by means of it the disease could often be arrested, and the further progress of the pathological changes permanently stopped. He advised that its use in locomotor ataxia should be supplemented by the application of the faradic brush to the spine. He had also used the chloride with remarkable success in fibroid kidney. In the form of hypochondriasis connected with changes in the cerebral vessels it was very effective. He recommended it in various forms of spasm, among which he mentioned asthma and laryngismus stridulus, and said that in the latter affection one of his medical friends now used no other remedy. In certain cases of sexual debility accompanied by extreme hypochondriasis no remedy was so serviceable, and it seemed to him that there was some truth in the ancient motto that "Gold is a cordial to the mind." In simple sexual debility its use was sometimes followed by remarkable increase of power, and in dysmenorrhœa and in chronic metritis with scanty menstruation it had been found to be of benefit. More extended experience was, of course, needed to prove what the real position of this agent was in medicine.

Dr. Dana said that he had a female patient suffering from hysterical melancholia, who had previously been under the care of a homœopath, who said that the latter had given her gold (in first dilution), and that it had always given her relief. Whether this was a mental or a therapeutic result he was not prepared to say.

Dr. Bannister said that he had once treated some patients suffering from melancholia with chloride of gold for a number of weeks, but had not observed any effect from its use. He had, however, never used the double chloride of gold and sodium.

Friday, June 20th—Third Day.

Afternoon Session.

COMMITTEE ON NOMENCLATURE.

On motion of the Secretary, Dr. Wilder's resolution providing for the appointment of a committee of five on macroscopic encephalic nomenclature, with instructions to report at the next meeting a list of such terms as in their judgment may properly be recommended for use, was adopted, and the Chair appointed the committee as follows: Dr. E. C. Spitzka, Chairman, and Drs. B. G. Wilder, T. A. McBride, W. A. Birdsall, and L. C. Gray.

On motion of Dr. Bartholow, the other two resolutions offered by Dr. Wilder were referred to this committee.

The Vice-President, Dr. Birdsall, having taken the chair, The President, Dr. Isaac Ott, read a paper on

THE RELATIONS BETWEEN INJURIES OF THE SPINAL CORD AND THE EXCRETION OF CARBONIC ANHYDRIDE.

By means of Arsonval's calorimeter and Voit's respiration-apparatus, he has made a series of experiments upon the lower animals (rabbits and cats), and has arrived at the conclusion that injuries of the cord produce, as a rule, an increase of the excretion of carbonic anhydride. It does not seem to make any difference whether the gray or white matter, or both together, are injured, the increase ensues just the same. Although the calorimeter was kept at 100° F., in only two cases out of seven did he see any increase of temperature. In all the others it fell below normal.

DR. G. L. WALTON, of Boston, read a paper entitled

A CONTRIBUTION TO THE STUDY OF HYSTERIA BEARING ON THE QUESTION OF OÖPHORECTOMY.

The question of oöphorectomy, he said, should be limited to those cases in which the hysteria is secondary to abdominal trouble, and carefully exclude those in which the menstrual irregularities and ovarian tenderness are secondary to the hysteria. Whether the operation should be limited to cases of organic pelvic disease cannot be determined with certainty; but this is at present the safer plan. The most plausible explanation of hysterical hemianæsthesia (common after ovarian irritation) is that of spasmodic contraction of the cortical bloodvessels of the brain, suspending the function of the cortical nerve-cells through lack of nutritive fluid. This theory explains best, for example, the rapid onset and disappearance of the symptoms; for we know that a thought is sufficient stimulus and an instant sufficient time to cause the most extreme changes in the calibre of bloodvessels, as instanced in the blush, on the one hand, and the pallor of fear on the other. That such sudden changes take place in the brain, as well as in the integument, is shown by the phenomenon of fainting, in which the cerebral functions are entirely suspended, presumably through the lack of blood. The transfer of anæsthesia from side to side with succeeding oscillations is suggestive of the ebb and flow of a fluid. That vaso-motor irregularities are common in hysterical patients in other parts of the body as well as the brain, is evidenced by the frequency of chills, flushes, and ischæmia, sudden swelling of the joints, etc. Weight was thrown on this theory, he continued, by the case published in a paper by him on oöphorectomy in hysteria in the *Boston Medical and Surgical Journal*, of June 5, 1884. In this case, right-sided hemianæsthesia coincided with left-sided angio-spasmodic migraine and left-sided intermittent retinal ischæmia (the bloodvessels of the right eye being normal). The only explanation to be offered was that spasm of bloodvessels by implicating the membranes caused the pain by extending into the cortex, the hemianæsthesia of the opposite side, and by reaching to the eye evidenced itself in the abnormal contractility of the retinal vessels of the same side. The starting-point in this case was pelvic disease, probably by irritation of the sympathetic nerves supplying the ovarian region. In favoring this theory he said he was dealing with a tangible phenomenon of which we had constant examples, and could not, therefore, be accused of a flight of imagination. He had failed to produce "transfer" in hysteria secondary to pelvic disturbance, but had observed it frequently in cases of constitutional hysteria. This was probably because the unilateral spasm was kept up in the one case by the organic trouble, while in the others the sympathetic irritability is alike on both sides of the brain; so that while the vessels are contracting on one side, they are dilating on the other. In conclusion, the case referred to (the principal points of interest in regard to which were given in the paper mentioned) was reported in detail. The patient was operated on by Dr. Barss; the removal of both ovaries, which were found to be in a state of cystic degeneration, being followed by marked improvement in hysterical convulsions and hemianæsthesia of thirteen years' standing.

DR. E. C. SPITZKA said that he had given some serious attention to this subject, and that he was free to confess that he was, at the present time, very far from being as clear in his own mind in regard to it as the author of the paper apparently was. If his theory was correct, he could hardly understand why the operation for the removal of the ovaries should not be followed by immediate relief. In the particular case which he had related, the improvement noted was not greater than often occurred spontaneously. Troubles such as he had described were liable to occur without any disease of the ovaries whatever. As to the author's vaso-motor explanation, it was theoretically very pretty; but the fact unfortunately remained that in reality we knew nothing at all about the matter. Dynamic conditions, in his opinion, offered a more satisfactory explanation. He then mentioned a case of his own, which, he said, had taught him a lesson, and which had rendered him very conservative in regard to Battey's operation. In great part, in deference to the opinion of eminent gynecologists, he gave his consent to having the operation performed in this instance. One ovary was removed, and, on examination, it was found to be but little diseased; but, in five days afterward, the patient died, without there having been the slightest change in any of the symptoms. In conclusion, he mentioned a case of hysteria and hystero-epilepsy, at the Breslau clinic, in which a cure was effected by the performance of a sham operation, the patient firmly believing that the ovaries had been actually removed.

DR. C. K. MILLS, of Philadelphia, stated that, in his opinion, in the vast majority of cases operated upon, relief might have been afforded without resorting to this extreme measure. All, he thought, had seen instances of hysteria, with symptoms as severe as those recorded in Dr. Walton's patient, in which this was the case. He then mentioned a case of hystero-epilepsy in which the clitoris and both ovaries were removed, and yet in which, notwithstanding the extent of the operation performed, the patient admitted that she had the same inclinations, and suffered from many of the same symptoms as before, while her mental condition, he thought, was worse in many respects. He believed that we should hesitate very long before recommending an operation of this kind for the relief of hysteria, since, in his opinion, hysteria, except in very rare instances, was not dependent on uterine or ovarian disease. The tendency to operate was very great at the present day, and in two instances that he knew of in which an operation was recommended, the functions of the ovaries had never been established. It would have been much better in these cases, he thought, to endeavor, by every possible means, to secure the establishment of these functions.

DR. J. P. PUTNAM, of Boston, remarked that he could not say that he subscribed to the theory of Dr. Walton; but, at the same time, he could not say why, in certain cases, the operation was not justifiable, just as it was acknowledged to be proper to remove other sources of peripheral irritation. Thus, eye-strain, although he thought its importance in the causation had been exaggerated, was sometimes one of the factors in the production of cerebral disease, and in a certain number of cases the relief of the eye-strain was followed by some amelioration of the trouble.

DR. ROCKWELL said that, in his position, in connection with the New York State Woman's Hospital, he had had ample opportunities for observation in this class of cases, and that he could not but acknowledge that in this institution the operation was performed, as a rule, only in those in which it was proper that it should be. He was convinced, however, that there was a considerable minority of cases in which symptoms were attributed to disease of the ovaries which were not in reality referable to this cause. In the Woman's Hospital, he had often noticed that hysterical, neuralgic, and abnormal sensory symptoms were completely relieved, while ovarian and uterine disease, of which the patient was the subject, remained in the same condition as before. He knew of at least one case also in which it had been proposed to remove the ovaries in which he had himself succeeded in securing a perfect cure by other means. Great care, he thought, therefore, should be used in the selection of cases for operation.

DR. MARY PUTNAM JACOBI, although not a member, having been invited to participate in the discussion, related two or three cases which had come under her observation, and made the point that whenever it could be shown that the ovaries were enlarged and prolapsed, and that they had resisted various methods adopted to restore them to their normal condition, it could be inferred that there was cystic degeneration of these organs. When cystic degeneration was determined to be present, it was only a question of time when they should be removed, for this procedure then became a positive necessity unless, as occasionally occurred, the ovary became converted into one large cyst; in which case it constituted an indolent tumor which gave rise to very little pain or other disturbance. In one case of this latter kind, with which she was acquainted, the patient had no trouble at all, except moderate dysmenorrhœa. On the other hand, there were cases in which there was no objective disease of the ovaries in which there were still some hysterical and neuralgic symptoms. It was this class of cases in which it was entirely questionable whether the operation would afford any relief, even in instances of the most violent pelvic neuralgia. In many cases, while removal of the ovaries put a stop to menstruation, it did not stop the pain; the neuralgic condition remaining the same as before. She did not know whether it had ever been suggested that the pain in cerebral hysteria (that is in cases in which the trouble could be referred to no local cause) was precisely analogous to the aura of epilepsy, which was supposed to indicate that certain changes were taking place in the cortex of the brain.

DR. WALTON said, in closing the discussion, that hardly anyone could be more conservative than himself in regard to the operation, unless it was some one who thought that this procedure ought never to be resorted to; since it was only in cases in which the hysterical symptoms were obviously secondary to pelvic disease that he would recommend it. To the objection that removal of the ovaries did not always cause immediate relief he would reply, that there were many cases in general practice in which a secondary condition was not relieved by the removal of the original cause, as, for instance, the extraction sometimes of a tooth whose condition had given rise to facial neuralgia. One cause why the relief had not been greater in the case which he had reported, he thought, was that the Fallopian tubes had been allowed to remain (the operation performed being Battey's instead of Tait's). Tait had repeatedly found that menstruation was very apt to continue unless the tubes, as well as the ovaries, were removed. Still, but a comparatively short time had as yet elapsed since the operation, and he trusted that the improvement would become greater as this period extended. He was quite willing to accede to the proposition that all these troubles might exist without there being any disease of the ovaries, and on this account he thought that the greatest possible caution should be observed in advising operative interference. If cases could be relieved without operation, he thought that all other means should be employed, and that in every instance the operation should be reserved as the last resort. As to hysteria *alone*, it was rare that one was called upon to advise operation for its relief. He agreed with those who believed that hysteria was almost always of cerebral origin, and that it was only in a comparatively few cases in which it was dependent on uterine or ovarian conditions. To sum up, he was in favor of operating only in those cases in which we were reasonably sure that organic disease of the ovaries was present.

DR. JAMES J. PUTNAM, of Boston, read a paper on

TYPICAL HYSTERICAL SYMPTOMS IN MEN, DUE TO INJURY, AND THEIR MEDICO-LEGAL SIGNIFICANCE,

during the course of which he related a case of railway injury followed by hysteria, and stated that in a medico-legal aspect, at least, it was very unfortunate that there should not be some standard of opinion established in regard to this subject on account of the confusion which now existed, and for which Erichsen was, to a considerable extent, responsible. The medical opinion in reference to hysteria was, as a rule, very different from that existing in the public mind, and the views of authorities like Erichsen and Page were completely opposed to each other.

DR. DANA said that he was particularly interested in this subject, as within a recent period he had been called upon for an opinion in two cases, in the one on behalf of the patient and in the other on behalf of a railroad company that was being sued for damages in consequence of injuries inflicted on a passenger. He therefore fully appreciated the difficulties to which Dr. Putnam had alluded. There was one point, however, to which he had not referred. Hysteria was, no doubt, a serious disease; but the question arose in every case such as he had described, whether the hysterical symptoms were due to the accident or were excited by the hope of reward. There are two classes of cases in which hysteria was liable after accidents. The first was where serious injuries were received, and the patient suffered immediately. The second was of two kinds: (1) those in which symptoms slowly developed, as in chronic meningo-myelitis, and (2) those in which there might be spinal concussion, followed later by hysteria or hypochondriasis. He had not found the existence of hemianæsthesia in men, as Dr. Putnam had. There was one objective symptom which might perhaps be of some value, and that was electric resistance.

DR. PUTNAM thought that this whole subject ought to be regarded from a different point of view than that from which it was now regarded. The slightness of the

injury did not seem to be of much consequence. In his own case the injury had been slight, and yet from the very first day he had been seriously affected. No thought of obtaining damages, he believed, could have had any effect in originating the hysterical trouble in this instance. He advised that sensibility should be tested in all respects for hemianæsthesia; the special senses as well as the skin. The question of atrophy was interesting in this connection. Flattening of the muscles, accompanied with a somewhat diminished temperature would be proof that the parts claimed to be paralyzed had been kept in one position for a long time, and the presumption would be, therefore, that the individual was not feigning. Electrical resistance, he argued with Dr. Dana, was an important point.

DR. SARAH J. MCNUTT, of New York, reported a case of

DOUBLE HEMIPLEGIA.

The patient was a child who had never walked or talked, and who died of broncho-pneumonia, with convulsions. The disease of the brain from which it suffered was attributed to injury to the head received at the time of birth. At the autopsy marked atrophy of the cortex (greater in the right than in the left hemisphere) was found on both sides, involving principally the paracentral lobule, the anterior central convolutions and the upper two-thirds of the posterior central convolution. The disease was pronounced by Prof. William H. Welch to be sclerosis of the greater part of the motor tract, with degeneration of the pyramidal tracts. There were no lesions in the vicinity of the island of Reil, but in the larynx there were found vegetations on both vocal cords, consisting of the natural tissue of the part.

EVENING SESSION.

On the unanimous recommendation of the Council, Dr. Augusta Foul, Professor of Psychiatry in the University of Zurich, Switzerland, who had been nominated by Drs. Seguin and Ott, was elected

AN ASSOCIATE MEMBER.

DR. W. R. BIRDSALL, of New York, read a paper on

OPHTHALMOPLEGIA EXTERNA PROGRESSIVA,

in which he reported two cases of slowly progressive paresis of all the external muscles of both eyes (the levator palpebrarum, the recti, and the obliqui) producing partial ptosis and nearly complete immobility of the eyeballs, with complete preservation of the functions of the internal ocular muscles (iris and ciliary muscles), accommodation being normal, and reaction of the iris to light and accommodation movements also normal. There was no perceptible lesion of the fundus. Vision was normal in one case, and defective from irregular astigmatism in the other. There was no evidence of disease in any other cranial nerve or in any part of the body. There was no heredity, and no signs or suspicion of syphilis. The patients were both males, aged respectively seventeen and twenty-nine. Slow improvement occurred in one case under large doses of iodide of potassium, and in the other, under the use of the same drug and faradization of the eyes. One case was referred to him from the hospital service of Prof. D. B. St. John Roosa, and the other by Dr. Wilson, of Bridgeport, Conn. Both cases were still under treatment.

Dr. Birdsall held that the lesion could not be due to intraorbital disease, nor to an intracranial lesion involving primarily the trunks of the nerves implicated, on account of the escape of those branches of the third nerves which supply the iris and ciliary muscles; and that it must therefore be an affection of the nuclei of the sixth, fourth, and parts of the third nerves, which supply the external ocular muscles—these parts representing an associated system concerned in movements of the eyeballs and in lifting the upper lids, somewhat distinct from the iris and ciliary muscles, which are more intimately connected with the functions of the optic nerve in the regulation of light, and are probably supplied, as far as the sphincter iridis and the ciliary muscles are concerned, from nuclei in close proximity to, but distinct from the nuclei of origin of the remaining third nerve-fibres, which supply the external ocular muscles. A gross lesion, such as a neoplasm, meningitis, arteritis, or a local softening, could hardly affect so widely separated nuclei as the third, fourth, and sixth nerves, and not at the same time affect the ciliary and pupillary centres, those of the fifth and seventh nerves, or other neural tracts. Degeneration within this system of associated muscles, nerve tracts, and centres, similar to the degeneration of progressive muscular atrophy and of labio-glosso-pharyngeal paralysis, appeared to be the most consistent theory of the pathology of these cases.

Dr. Birdsall stated that Hutchinson, in 1869, had advanced this view, based on an atrophy in which this lesion was found by Dr. Gower, to account for this class of cases, which Von Graefe first called attention to. In most of Hutchinson's cases (which were seventeen in number), however, the iris and ciliary muscles were also affected. Other portions of the nervous system, in addition, were implicated in all his cases, so that none of them were exactly parallel to the two now presented, which were apparently unique. Dr. Roosa had exhibited them at the New York Ophthalmological Society, and none of those present had ever met with similar cases, with the exception of Dr. Kipp, of Newark, N. J., who stated that he had seen one case which he thought was identical. This case, however, had never been published. In conclusion, Dr. Birdsall referred to some other allied cases reported by different authors, and spoke of certain relations between tabes dorsalis and progressive muscular atrophy, as well as of syphilitic ocular affections.

DR. SPITZKA thought that Dr. Birdsall's explanation of these cases was probably the correct one. Such troubles were analogous to bulbar paralysis; but there was one difficulty about accounting for them which did not exist in the case of the latter, and that was the great distance between the nuclei of the fourth and the sixth pairs of nerves.

DR. BIRDSALL said that he looked upon the parts mentioned in his paper as associated functionally, and that was the view adopted by Hutchinson. This paralysis, he thought, was a systemic affection, and the reason that he felt obliged to adopt the theory of degeneration was, the greater difficulty of accounting for the trouble by a gross lesion, on account of this very distance between the nuclei of the different nerves involved.

LOCOMOTOR ATAXIA AND SYPHILIS.

DR. E. C. SEGUIN had expected to contribute a paper entitled "A Study of the Etiology of Tabes Dorsalis

with Special Reference to the Efficiency of Syphilis," but was prevented from doing so, as well as from being present at the meeting, by illness. He therefore merely sent some statistics of his cases, which were now read by Dr. Birdsall. There were 72 cases in all; and of these, 22, or 30 per cent., had had chancre, and 16, or 22.2 per cent., chancre followed by secondary symptoms. In 14 cases, or 19.8 per cent., there had been neither chancre nor secondary symptoms, and in 20, or 28 per cent., there was no mention of syphilis. Dr. Birdsall said that in 43 cases seen by him, 9.5 per cent. had had syphilis. His patients had been mostly hospital cases, while Dr. Seguin's had been mostly in private practice.

DR. SPITZKA said that before 1881 he had seen 61 cases of locomotor ataxia, and since 1881, 23 cases. Of the latter series, in which greater care had been taken to secure accurate histories, over 80 per cent. of the patients had had syphilis. But, what he thought was of more value than any figures, he was able to report one case of complete cure by vigorous antisyphilitic treatment. It was a typical case of ataxia (which had at one time been so great that the patient was confined to bed), with the Argyll-Robertson pupil and other pathognomonic signs of the disease; and now it was perfectly cured, with the exception that there was a slight asymmetry in the patellar tendon reflex (which had been completely lost), this being a little fuller than normal on one side, and a little less than normal on the other.

DR. ROCKWELL had seen forty-four cases, all in private practice, and seventeen of these were syphilitic. Of the forty-four, six were women, and two of these were syphilitic. He had no doubt that a much larger proportion of his cases than seventeen had really had syphilis, if the truth were known, and it was his firm conviction that syphilis existed in a majority of all the cases of ataxia, and was by far the most important factor in the etiology of the disease.

DR. PUTNAM had seen 34 cases, and of these about fifty per cent. were syphilitic. In none of the latter, however, had anti-syphilitic treatment been successful.

DR. LEONARD WEBER, of New York, repeated the statistics which he had given in his paper read recently before the Academy of Medicine. These, he said, would seem to indicate that syphilis played quite an important *rôle* in the etiology of ataxia; but by no means so important as claimed by Erb, Fournier, and others. He was not so sanguine in regard to antisyphilitic treatment as some others. In his experience, when there was a rapid development of tabes in the course of syphilis (the ataxia being due to multiple lesions, probably in the lepto-meninges, and not to true sclerosis of the cord), there was a fair prospect of securing relief; but in the more slowly developing cases of tabes, in which the patient had had syphilis twenty years before, he had yet to see the first case in which any improvement took place. The great expectations of success which had been raised by the announcement of the syphilitic origin of ataxia by Erb and Fournier, he thought, had been by no means realized.

DR. C. L. DANA, of New York, read a paper entitled

FOLIE DU DOUTE AND MYSOPHOBIA.

He referred to the history of *folie du doute*, or the "doubting madness," which had been chiefly studied by the French writers. Griesinger and Berger had also described a psychopathic symptom which belonged to the same category and had called it *Grübelsucht*, or metaphysical mania. In *folie du doute* the patient was harassed with a constant desire to question, speculate, and repine over details. His mind was never settled, but was in a condition of "pruritus." It was a psychopathic symptom, which indicated that the patient was a monomaniac and truly insane, or only hypochondriacal, or profoundly neurasthenic and hysterical. It was the form in which *primäre Verrücktheit* sometimes developed. Mysophobia, or fear of contamination, was a symptom indicating probably a similar condition. *Folie du doute* had been divided by Ball into several varieties, such as the suspicious, the calculating, the timid, and finally *tactile*, and mysophobia had been classed as the tactile form of *folie du doute*. This classification was open to criticism, but Dr. Dana was inclined to think it was correct.

He then related two cases, one a typical one of *folie du doute*, as described by Falret, Ball, and others, and the other one of mysophobia, as first described by Hammond. The first patient was a married man of thirty, of a phthisical, but not neurotic, family history, who had indulged in much sexual excess. He was tormented and worried continually as to the ordinary details of his daily life. He had to wash, shave, eat, drink, exercise, work, etc., in a particular way or else he was wretched. The trouble was of ten years standing. Medicinal treatment was tried, but did not have the slightest effect; under a system of moral training and education considerable improvement had been secured, and in his efforts in this direction Dr. Dana had been ably seconded by the man's wife, who was a sensible and intelligent woman. Notwithstanding his infirmity, the patient had always been able to discharge with ability his business duties, which were those of a bookkeeper.

The second patient was a single woman of twenty-eight, of healthy family history, but of hysterical temperament, who for six months had suffered from fear of dirt and contamination, exhibiting the typical symptoms described in cases reported by Hammond, Shaw, Seguin, and Russell. She had never had convulsions or chorea, and was free from uterine disease. Dr. Dana had seen her only once, in consultation, and she did not seem to be very anæmic. She presented the appearance of a hysterical woman, and he also noticed that she seemed to have been the subject of facial paralysis. When she protruded the tongue it deviated decidedly to one side. Under the use of ferruginous and other tonics, as well as of moderate doses of the bromides, she had already improved to some extent, and he had advised that moral influences should be brought to bear upon her a little more forcibly than had hitherto been the case.

In conclusion, Dr. Dana suggested as points for discussion the relation of mysophobia to *folie du doute* and *Grübelsucht*, and the question of the proper interpretation of morbid fears in general.

DR. SPITZKA said that the class of patients described by Dr. Dana, although of perfectly sound mind in all other respects, were suffering from *bona fide* insanity. In male patients, the one great cause was masturbation. The treatment should be both medicinal and by moral

means, and was best conducted in a small country home, where eight or ten patients were received. He suggested *imperative conception* as a much better term than morbid fears.

DR. G. BETTON MASSEY, of Philadelphia, read the report of

A CASE OF SUDDEN LOSS OF VISION FOLLOWING ANÆSTHESIA OF THE FIFTH NERVE, WITH REMARKS ON THE MODIFYING EFFECT OF ANÆSTHESIA ON THE GALVANO-REACTIONS OF THE SPECIAL SENSES.

The patient was a farmer, forty-eight years of age, who three years before coming under observation noticed numbness of the left side of the face. This increased steadily for about two years, and was accompanied by heaviness and pain in the head, felt mostly on the left side. At the end of that time vision became impaired in the left eye, and in ten days was totally lost. Ophthalmoscopic examination by Dr. William Thomson at this time showed white atrophy, the disk being snow-white. He was then placed under the care of Dr. S. Weir Mitchell, who gave him increasing doses of iodide of potassium, and later the bichloride of mercury in small doses. One year afterwards, on the 8th of February, 1884, he found the right eye failing, and in one week it was entirely blind. Examination showed no light-perception in either eye. Both pupils were very small, and both upper eyelids were kept up by forced effort. The ophthalmoscope showed no decided change except, perhaps, overfulness of the retinal vessels. No cause could be assigned for the attack.

The patient was now referred to Dr. Massey for treatment. Over the left eye there was a partially anæsthetic spot, about four centimetres long, by three wide, oval in outline, and extending laterally. Electrical excitation of this area by placing both poles within its limits, developed the following facts: Faradic current, sensation lessened; galvanic current, local effect on blood-vessels of skin normal. The local galvanic sensations, however, presented a decided deviation from the normal—the sensation of burning being normal, but the sensation of tingling about two-thirds lessened. Having mentioned his observations in regard to gustation, vertigo, and vision in the case, Dr. Massey stated that, at the present time, the patient had been for two months under a treatment consisting of galvanic interruptions to the eyes and numb spot, and increasing doses of sulphate of strychnia, and that as an apparent result there had been a decided increase of sensation in the left brow, and occasional flashes of light in the eyes.

Fearing that the remarkable lessening of normal vertigo and taste originally found in this case might be due to an increased resistance at the anæsthetic spot, he carefully estimated the amount of current actually passing through the circuit by the deflection of a galvanometer needle, and found that this deflection was exactly the same for each side. The amount of electricity passing, therefore, could not have been different, and the difference in the results on the two sides could only be explained by placing these phenomena in the already large list of reflex actions—the integrity of one side of the arc in this case being impaired, with a corresponding impairment of the phenomena. This solution of the "electric taste" and the "electric flash" had been suggested some years ago by Althaus, in his work on "Electro-therapeutics." Besides a corroboration of the facts observed by him, the importance of the present case, Dr. Massey thought, consisted in the clear relation established between the restoration of sensation and the return of the phenomena.

DR. GEORGE W. JACOBY, of New York, had prepared a paper on

CEREBRO-SPINAL SATURNISM,

but owing to the lateness of the hour, he did not read it. Instead of this, he reported briefly one of the cases described in it, which was one of locomotor ataxia, which he believed to be due to lead-poisoning, and which recovered under the use of iodide of potassium, with the exception that the tendon reflex was not restored. The literature on this subject, he said, was extremely meagre, and he had been able to find only three other cases mentioned.

DR. AMIDON could not see why lead-poisoning should not be a cause of ataxia as well as arsenical and mercurial poisoning and diphtheria.

DR. BIRDSALL said that he had often noticed in patients suffering from lead-poisoning a tremor which amounted almost to ataxia, but he had never seen one with real ataxia of the lower extremities.

DR. DANA thought that, as lead-poisoning was so very common, ataxia would be oftener noticed in connection with it if it were one of the causes of that disease, and that it would require a considerable amount of evidence to prove that Dr. Jacobi's case was really due to this cause.

The Association then adjourned.

RHODE ISLAND MEDICAL SOCIETY.

Annual Meeting, held at Providence, June 19, 1884.

(Specially reported for THE MEDICAL NEWS.)

THE Society met in Lyceum Hall, Providence, THE PRESIDENT, DR. JOB KENYON, in the Chair.

DR. GEO. D. HERSEY read

THE SECRETARY'S ANNUAL REPORT,

which stated that the Society had held four meetings during the past year; that four deaths had occurred among the Fellows, two had removed from the State. The present active membership is 187, nine new Fellows having been received during the year.

DR. C. W. PARSONS read the report of the trustees of

THE FISKE PRIZE FUND.

The sum of $300 has recently been awarded to Dr. Chas. V. Chapin, of Providence, for the best essay on "The Origin and Progress of the Malarial Fever now Prevalent in New England." No award was made on the other proposed subject.

For the year 1885 the following subjects are submitted, for the best essay on either of which, a prize of two hundred ($200) dollars is offered:

(1) "Original Investigations in Household Hygiene."

(2) "The Present State of the Germ Theory of Disease."

(3) "Physiological and Pathological Effects of the Use of Tobacco."

(4) "Migraine, its Nature and Treatment."

THE REPORT OF THE BOARD OF CENSORS

was presented by Dr. J. W. C. Ely. The following gentlemen were recommended for Fellowship and subsequently elected: Drs. Henry S. Swan, William A. Tremaine, Byron J. Lillibridge, Sanford S. Burton, Benjamin R. Symonds and Abraham L. Falcon. The Board also recommended Dr. Lloyd Morton, of Pawtucket, for Anniversary Chairman for 1885.

THE REPORT OF THE TREASURER,

DR. C. H. LEONARD, showed a balance of cash on hand of $218.88. Upon motion of Dr. Hersey, it was voted to transfer $200 of this balance to the printing fund, which would then amount to $1733.43.

DR. T. NEWELL reported for

THE LIBRARY COMMITTEE

that there were 3586 volumes in the library; showing an increase of 1083 volumes for the year. The invested building fund now amounts to $542.90. Dr. H. G. Miller, of the same committee, said that the Society had been remarkably favored in securing at a reasonable price seven hundred volumes from the private library of the late Dr. David King, of Newport, the purchase having been made at the auction sale in New York. Many of these volumes were exceedingly choice and valuable.

DEATH OF DRS. PERRY AND BULLOCK.

Dr. W. E. Anthony, of a committee embracing also Drs. J. H. Eldredge and A. Ballou, presented the following preamble and resolutions, which were adopted.

Whereas, In the decease of Drs. Otis Bullock and Thomas W. Perry this Society has lost two members who had long been connected with it;

Resolved. That we desire to place on record our appreciation of those traits of character by which they had attained such a position of usefulness and honor in the Society and in the community, Dr. Bullock was for one year President of the Society, and for forty years was a member of the Board of Censors, and, as such, conscientiously fulfilled all the duties pertaining to the office with unfailing kindness and courtesy. Dr. Perry was a frequent attendant on our meetings, and often contributed the result of his large experience to the discussions.

DR. LLOYD MORTON, Chairman of the Committee on

THE LEGISLATIVE BILL FOR THE APPOINTMENT, ETC., OF MEDICAL EXAMINERS,

reported that the bill, in a considerably modified form, had already become a law, and would go into effect July 1st, proximo. It was then voted to accept this report, and to discharge the Committee, with the thanks of the Society for their efficient services.

OFFICERS FOR THE NEXT YEAR

were then elected as follows:

President.—Oliver C. Wiggin, M.D., of Providence.

Vice-Presidents.—H. G. Miller, M.D., of Providence; John W. Sawyer, M.D., of Providence.

Recording Secretary.—George D. Hersey, M.D., of Providence.

Corresponding Secretary.—E. M. Harris, M.D., of Providence.

Treasurer.—Chas. H. Leonard, M.D., of Providence.

Board of Censors.—Drs. Ariel Ballou, James H. Eldredge, J. W. C. Ely, George P. Baker, S. S. Keene, Benjamin Greene; Edward T. Caswell, and Eugene Kingman.

It was voted to hold the *September meeting* of the Society in Providence.

THE ACTION OF QUININE.

DR. GARVIN, of Lonsdale, said that in view of the very mistaken and, in many instances, harmful, impression that exists in the minds of many people regarding the effects of quinine on the system, he wished to offer the following:

"*Resolved*, that the use of quinine in the treatment of intermittent fever, leads to no injurious after-effects."

In the course of a brief discussion on the resolution, Dr. A. Ballou said it seemed to him to be hardly becoming the dignity of the Society to take such action. In this sentiment the Society evidently concurred, as the resolution was not adopted.

The *Annual Address* was then delivered by Prof. Geo. I. Chace, of Providence, after which the Chair called upon the President-elect, Dr. Wiggin, who made a brief but graceful speech of appreciation of the honor conferred on him.

The Society then adjourned to the Narragansett Hotel to dine, Dr. J. W. C. Ely acting as Anniversary Chairman.

KENTUCKY STATE MEDICAL SOCIETY.

Thirty-ninth Annual Meeting, held at Bowling Green, June 3, 4, and 5, 1884.

(Specially reported for THE MEDICAL NEWS.)

(Concluded from page 713.)

WEDNESDAY, JUNE 4TH—SECOND DAY.

AFTERNOON SESSION.

DR. PINKNEY THOMPSON, of Henderson, read a paper on

TYPHOID FEVER,

which, he said, is a disease that has a distinct clinical history and runs a distinct course, and in his judgment is never aborted by remedies. The paper elicited considerable discussion in reference to treatment.

DR. A. W. JOHNSTONE, of Danville, read a paper on *Litholapaxy*.

DR. DUDLEY S. REYNOLDS then spoke on *Inflammations of the Iris*.

THURSDAY, JUNE 5TH—THIRD DAY.

DR. S. D. FINCK, of Louisville, read a paper on *Phlyctenular Conjunctivitis*.

DR. W. M. FUQUA, of Hopkinsville, read an elaborate paper on *Civilization and Sanitation*.

DR. WM. CHEATHAM, of Louisville, read a paper upon

SYMPATHETIC OPHTHALMIA,

in which he presented the following conclusions: Enucleation is better performed in the stage of irritation; if it cannot be performed then, operate in the stage of inflammation, for while there is life in the eye there is hope. It should not be performed in iritis serosa. It can be performed at the onset of irido-cyclitis, although

the eye causing the sympathetic inflammation may not be blind.

The following resolution was adopted on the

DEATH OF DR. SAMUEL D. GROSS.

Whereas, the late Dr. Samuel D. Gross, of Philadelphia, was one of the earliest Presidents of this Society, and always on its rolls, it is fit that we should formally add our meed of respect to his memory.

What we shall say of him is much to us, though it is but a small part of the large sum of testimony to his worth going up from medical men in both hemispheres. In recognizing his high merits we shall join company with the most dignified and venerable institutions of learning known to the English-speaking race; institutions that have done themselves honor in bestowing honors upon him. It is some comfort to us who mourn him, that in the corporate existence of this organization, of which he was a founder, *he still lives*. To our remotest year his name shall stand as that of one upon whose full and excellent life every member may well wish his own were modelled.

Resolved, That as he was a great surgeon and leader of thought we shall continue to hold his precepts in high esteem. As he was a kind and loyal friend we shall cherish our memories of his personal dealings with us; as he lived frankly, purely, and courteously, we shall reverence in him the gentleman above reproach.

DR. S. H. STUCKY, of Louisville, read a paper on *Catarrhal Headache and Its Allied Affections*.

DR. J. M. MATHEWS, of Louisville, read a paper on

OPERATIONS UPON HEMORRHOIDS DURING THE INFLAMED STATE.

He held that a pile is a tumor, and he took issue with those authorities who characterized this tumor as a vascular tumor. He maintained that it is a tumor which is well supplied with blood; the vessel which feeds it can be felt at the top pulsating with a beat almost equal to that of the radial artery. He defined three varieties of these tumors: First, the capillary, in which the small vessels push into the folds of the mucous membrane, without any infiltration at all. That is one kind; and it is a dangerous kind from the fact that the circulation is free and rapid. Being fed by an artery of considerable size, if ulceration takes place over it and perforate it, there is danger that the patient will bleed to death. If the chain of morbid phenomena be not here checked, and the inflammation is allowed to continue, it goes on to the formation of the second variety, the venous pile. Admitting the existence of piles, he asked, can the necessity of an operation be disputed? And he took issue with any one who claims to cure this kind of pile or tumor by anything else than an operation. From a variety of causes piles are liable to become inflamed, and, once inflamed, they may easily become strangulated by passage below the sphincter; everything is aggravated then, and it may take some weeks to quiet this trouble. It has occurred to him, why not operate upon them, and get rid of them at once. There is no authority that says, operate upon a pile during the inflamed state; but they will tell you to apply treatment to reduce the inflammation.

He then cited the following cases. A few weeks ago he was called in consultation to a distinguished lawyer, who was in this condition. The family physician in attendance had tried in vain to quiet inflammatory action for two or three weeks. He found hanging down from the anus two solid tumors; he passed the knife around them, and ligated them. He visited him the following morning, expecting to find him in some trouble. To his surprise and satisfaction, he was out of bed, and, in a week, out of the house.

Another case, a young man, had a mass of inflamed tissue hanging from him as large as his fist, which it would have taken weeks to abate. He ligated the whole mass. He went to see him the next morning, and was told that he had risen early and gone out. Three days later, he received a postal from Cairo, Ill., saying that his patient was that far on his way home, and was all right. When he got home, he wrote that he was entirely well. Since then, Dr. Mathews has had five or six cases of similar character, in which the proceedings and results were similar. He therefore concludes that, instead of applying remedies to relieve the inflammatory trouble, the tumors should be operated upon at once. The Society then adjourned.

NEWS ITEMS.

LONDON.

(*From our Special Correspondent.*)

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM met on June 5, and transacted some important scientific business.

PREVENTION OF BLINDNESS FROM OPHTHALMIA NEONATORUM.—DR. BRAILEY read the report of the Committee on this subject. In answer to a very large number of inquiries issued to private persons, ophthalmic and lying-in hospitals and institutions for the blind, twenty-three statistical replies, all of them from institutions for the blind, were received. Four of these, those of the Belfast Deaf, Dumb, and Blind Institution, the London Society for Teaching the Blind to Read, the Blind School at York, and the Blind Institution at Hull, were tolerably explicit, and the answers appeared from other evidence to be trustworthy. In the Belfast Institution, thirty per cent. of the persons concerned, owed their blindness to ophthalmia neonatorum. In the London Society, twenty per cent. were certainly blind from this disease; but from the extremely frequent occurrence of "congenital cataract" and "cause unknown" in cases of blindness from birth, the Committee were of opinion that at least another ten per cent. should be added, thus making again thirty per cent. In the Yorkshire School, forty-one per cent. were blind from this cause; and in the School at Hull, five cases out of fourteen (thirty-five per cent.), personally examined by Dr. Rockliffe, were with certainty attributed to the same disease. The statistics of the other institutions were inexplicit, but pointed to about the same results. The numbers agreed substantially with those of foreign investigators, notably those of Reinhard, who, on investigation of twenty-two German blind asylums, found six hundred and fifty-eight blind from this disease among a total of twenty-one hundred and sixty-five (thirty and a half per cent.).

The Committee recommended the adoption by the

Ophthalmological Society of the following resolutions (modified from those originally suggested by Dr. David McKeown, of Manchester):

1. That the purulent ophthalmia of newborn infants being the cause of a vast amount of blindness, mainly because of the ignorance of the public regarding its dangerous character and the consequent neglect to apply for timely medical aid, it is desirable to instruct those in charge of newborn children by a card, in substance as follows: "Instructions regarding newborn infants. If the child's eyelids become red and swollen, or begin to run with matter, within a few days after birth, it is to be taken without a day's delay to a doctor. The disease is very dangerous, and if not at once treated, may destroy the sight of both eyes." This is to be distributed through the medium of the Poor Law and Birth Registration Organization of the United Kingdom.

2. That the advocacy and aid of the medical press be solicited in drawing general attention and especially that of the authors of text-books of midwifery, of the lecturers on the same subject for students and midwifes, and of the various institutions which train, and charitable institutions which employ, midwives, to this important subject.

3. That a copy of the first resolution be forwarded to the respective Presidents of the Governing Boards of the United Kingdom.

The scientific affairs of the evening next occupied attention. It may be mentioned that Herren Becker, of Heidelberg, and Snellen, of Utrecht, were present.

MONOCULAR DIPLOPIA.—DR. BRAILEY communicated a case of this disease in a man aged fifty-six. He had paralysis of the right external rectus with dilatation of the pupil. The diplopia only existed in the outer half of the field of vision. The optic disks had subsequently atrophied. Red and green colors could not be perceived. The right knee-jerk was almost absent. The patient had had syphilis.

TUBERCLE OF THE CHOROID.—DR. MULES showed drawings and read a paper on this subject. The patient was a girl, aged ten, who died of acute miliary tuberculosis fourteen days after the apparent commencement of her illness. There was double optic neuritis, and surrounding the disk in each eye were eight or ten circular nodules, yellowish-white at the centre and passing gradually at the periphery into the color of the natural choroid.

SEROUS CYST OF THE IRIS.—DR. ADAMS FROST exhibited a case in a man aged twenty-eight. Twenty-four years before, the eye had been injured by a fork, and the development of the cyst dated from that time. Ten years ago an iridectomy had been performed. The cyst occupied the upper and inner quadrant of the anterior chamber. It would be difficult to remove the cyst, as it was in contact with the cornea and lens.

SARCOMA OF THE CHOROID.—MESSRS. COWELL AND JULER exhibited a glycerine jelly preparation and microscopic sections of a case of sarcoma of the choroid.

DISSEMINATED CHOROIDITIS.—MESSRS. CRITCHETT AND JULER exhibited a living case of disseminated choroiditis in a woman aged forty-six. There was a distinct history of syphilis acquired five years before. The case was chiefly interesting on account of the great number of large and small yellowish-white patches distributed over the fundus, including the yellow spot region of the right eye. Very little pigment was to be seen, and the visual acuteness and visual field of the right eye were normal. The left eye had become totally blind three years ago; presumably from the same cause.

MR. JONATHAN HUTCHINSON related a case in which the appearances were precisely similar, and which occurred in a young lady, aged fifteen, who was the subject of congenital syphilis, but there were no other manifestations of this diathesis at the time.

ACUTE OPTIC NEURITIS ASSOCIATED WITH ACUTE MYELITIS.—DR. SHARKEY read a very interesting paper on a case of this disease. The patient, a girl, aged seventeen, lost her sight in four days, November 9 to 13, 1883. There were no other symptoms of any sort. Severe double optic neuritis was found, and thirty-three days after her vision failed she began to complain of paralysis with loss of sensation, first in the left leg and then in the right. Anæsthesia gradually spread up the trunk and involved the arms, and she had incontinence of the evacuations. Cystitis came on, she passed offensive purulent urine, and the temperature reached 105° F. Finally, she died of peritonitis, sixty-two days after the blindness had begun and twenty-nine after the appearance of paralysis. At the necropsy, peritonitis, cystitis, and suppurative nephritis were found. To the naked eye the brain and its membranes were healthy. But there was softening of the cervical region of the spinal cord over a space of two or three inches in length. Microscopic examination revealed the presence of acute inflammation with softened cervical region in the columns of Goll above it, and in the lumbar enlargement, as well as in the optic nerves, disks, chiasma, and tracts, there was slight inflammation of the meninges about the chiasma and on the under surface of the frontal lobes. The etiology was quite obscure. Clifford Allbutt, Seguin, Noyes, Steffen, and Erb, had noticed the association of acute myelitis and optic neuritis, and more recently Dreschfeld and Chisolm. Gowers and Dreschfeld, thought they were associated phenomena due to a common cause. Clinically, such cases are of great importance, as they simulate coarse disease of the brain.

AMAUROSIS IN INFANCY.—MR. NETTLESHIP read a paper on amaurosis in infancy. He dwelt on the question of prognosis, and pointed out that there was a fairly well-defined group of cases in which the amaurosis was not recovered from; sight was absent or defective from birth, several children of the same parents were often affected and the parents were often akin. Some of the patients were idiotic, others stupid or weak, others quite intelligent; the optic disks were either healthy or atrophied; in the milder cases, in which sight was partly retained, there was often total color-blindness; in cases of absolute blindness, the pupils still reacted to light, which appeared to show that the centre for pupillary action in or near the corpora quadrigemina remained intact, although higher centres were absent or atrophied. In cases of amaurosis in which recovery was probable, the history was of great assistance; it was generally stated that the child could see well for some months or even years after birth, and then it lost its sight during an illness with cerebral symptoms often diagnosticated as meningitis; the optic disks in the great majority of cases were either

healthy or showed merely some slight doubtful pallor; frequently the power of walking, standing, or even sitting, was lost during the same illness. The blindness appeared to last from one to six months, and recovery took place slowly. He thought that in all these cases intracranial inflammation certainly took place, and perhaps spinal mischief as well. Possibly, in some cases, the blindness might be produced by pressure of fluid accumulated in the ventricles, but the explanation would not serve for all cases.

SANITARY PRECAUTIONS.—The Governor of Florida has forwarded to the Surgeon-General, U. S. Marine-Hospital Service, with his approval, a series of resolutions from the Board of Health of Tampa, Florida, requesting the establishment of a government quarantine station at the mouth of Tampa Bay, with a medical officer in charge, and enforcement of such quarantine regulations as the necessities of the case may require. The Board states that, in making the request, it is "influenced rather by considerations for the public safety than apprehension for the security of the town of Tampa, as the Board of Health reserve the right to, and can and will establish such quarantine by land as well as by water as may be necessary to protect the public health of the town from epidemic diseases should the necessity for so doing arise; but of course feel that an efficient quarantine at the mouth of the Bay would tend greatly to allay apprehension in this city as well as in the various towns and cities on the St. John's River."

A dispatch was sent to the Governor of Florida, informing him that an inspector would be stationed at such point as he might direct to tide over any emergency during the summer, but that regular quarantine buildings could not be built out of the present appropriation.

A telegram signed by the Governor of California, Mayor of San Francisco, and the State Harbor Commissioners, was received at the Treasury Department, stating that "there are no quarantine facilities at the port of San Francisco, the same are urgently needed, and the U. S. Government is earnestly requested to aid in providing the same." Answer was sent that the quarantine fund under control of the Department was not sufficient to establish quarantine buildings and necessary appliances, but that an inspector with boatmen and tents can be placed at such point as the Harbor Commissioners unite upon, to tide over the emergency.

DIPHTHERIA IN CAPE BRETON. — Information has been received, through the Secretary of State, from the U. S. Consul at Pictou, Nova Scotia, stating that diphtheria is so prevalent at several ports in Cape Breton that he has instructed his consular agents to advise masters of vessels bound to the United States to take out bills of health.

YELLOW FEVER IN MEXICO.—The deputy collector at Tucson, Arizona, under date of June 13th, says that yellow fever has reappeared at Guaymas, Mexico, where it prevailed so extensively last year. He adds that the sanitary laws are so lax in Mexico as to render it impossible to obtain authentic information, that burial permits are granted without a medical certificate, and no reliable data can therefore be obtained, but that the United States Consul at Guaymas is his authority for the reported prevalence of the disease and that there is little room to doubt the Consul's statement both as to its existence and fatal character, although the Mexican authorities are issuing "clean bills of health" to outgoing vessels, a course they pursued last year even after the pestilence assumed epidemic proportions.

THE CHOLERA.—Surgeon-Major McLeod, the health officer of Calcutta, under date of April 30, speaking of the excess of deaths for the month (1460, against 972 for the previous month), says: "This monthly total exceeds all the corresponding figures of the past decade, excepting 1878, and also exceeds the decennial mean by 318. . . . . There were 486 deaths from cholera, against 123 the preceding month. The number is very high, and exceeds all the corresponding figures of the past decade. It also surpasses the decennial mean by 275."

Consular reports from Calcutta give the following figures:

Week ending April 26,	174	deaths	from	cholera.	
" " May 3,	106	"	"	"	
" " " 10,	91	"	"	"	

Authentic information has been requested by the State Department from the U. S. Consul at Toulon, relative to the reported outbreak of Asiatic cholera in that city.

THE FIFTH INTERNATIONAL CONGRESS OF HYGIENE will be opened at the Hague on the 21st of August, and will continue in session one week. Applications for membership may be at once made to the General Secretary, Dr. Van Overbeck de Meijer, Professor of Hygiene at the University, Utrecht, Holland. Among the papers announced to be read are one on the "Attenuation of Virus," by M. Pasteur; on "Infectious Diseases," by Dr. Koch; and on the "Practical Application of the Doctrine of Infectious Poisons" by Dr. Von Kelnburg, of Bonn.

HOW TO PREPARE A 1 TO 1000 SOLUTION OF CORROSIVE SUBLIMATE.—SIR JOSEPH LISTER writes to the *British Medical Journal* (May 24, 1884), that one drachm by weight of a solution of one part of corrosive sublimate in one and a half part of glycerine contains two-fifths its weight, or twenty-four grains of the sublimate. This, multiplied by 1000 (the proportion of water required), gives 24,000 grains, which is very nearly three pints. It is, however, much more convenient to use fluid measure than weight, and a fluiddrachm of the glycerine solution referred to requires four pints of water to produce the 1 to 1000 solution.

M. PASTEUR.—It is stated that it is proposed to offer M. Pasteur a seat as life senator in the place of Mr. Wurtz, recently deceased. We also learn that the Minister of Public Instruction has obtained for M. Pasteur ground in the Bois de Boulogne, in which to prosecute his experiments with the virus of rabies.

SIR HENRY WENTWORTH ACLAND, K.C.B. — The many friends, on this side of the Atlantic, of Dr. H. W. Acland, Regius Professor of Physics at Oxford, will

be gratified to learn that the Queen has been pleased to confer upon him the dignity of Knight Commander of the Bath.

THE ANTIVIVISECTION AGITATION FROM A LAYMAN'S POINT OF VIEW.—George Augustus Sala, in his "Notes of the Week" in a late number of *The Illustrated London News*, writes:

"The Committee of the Antivivisection Society have sent me a circular referring to a meeting of the members and supporters of the Society to be held on Friday, May 9th.

"I have nothing to say, myself, against vivisection (when placed under proper legal restrictions), for the simple reason that for fifty years I have been in constant contact with the doctors, and have known some of the most eminent surgeons of the last and the present generations.

"I was, in early childhood, that which I once heard my mother's maid, in conversation with a friend, describe me as being 'a miserable little Hobject;' and the doctors were continually doing things to me. I am, in many respects, a miserable object now, and require to be periodically patched up by the faculty. And I will say naught against vivisection, because I never yet met with a cruel doctor; and because I firmly believe medical men to be among the most humane, the most generous, the most unselfish of mankind; and I indignantly denounce the imputation that there are any members of a noble, a high-minded, and a beneficent profession who, actuated by no more exalted motives than their 'greed after the hidden things of the life of the flesh,' confessedly and without compunction torture dumb animals. The medical man practises vivisection (with the smallest possible infliction of pain on the animal vivisected), not because he is selfishly greedy after 'the hidden things of the life of the flesh,' but because he wants to find out what is the matter with *you*, verbose Sir or sentimental Madam; because he is striving his utmost to devise means for saving *you* from misery and anguish; for mitigating the agony of the ills that rack the joints, or fire the veins, or that 'in the deeper vitals rage.' He is no worshipper of knowledge as of an idol. He tries during his whole laborious life to learn more and more, in order that he may console and relieve and preserve suffering humanity."

NEW MEDICAL JOURNAL.—The Italian journals announce the first number of *Commentario Clinico delle Malattie degli Organi Genito-Urinari*, published in Pisa by PROF. BARDUZZI. It is a bimonthly journal of forty pages.

THE ILLINOIS MEDICAL REGISTER.—The Illinois State Board of Health is now engaged in revising the Register of Physicians, preparatory to publication. Any changes or corrections should be promptly sent to the Secretary. Lists of the Officers of the Medical Societies in the State are also requested.

RESIGNATION OF PROFESSOR GOSSELIN.—Professor Gosselin, the acknowledged head of French surgery since the death of Nélaton, has, by reason of advancing years and impaired health, found it necessary to resign his Chair in the Faculté.

M. PASTEUR has been furnished with an opportunity of testing his theories concerning rabies upon the human subject. One of the servants of the Paris and Lyons Railway at Tarascon-sur-Rhone, having been bitten by an undoubtedly mad dog, has just placed himself in the hands of the illustrious savant.—*Brit. Med. Journ.*, June 14, 1884.

THE S. D. GROSS PROFESSORSHIP OF PATHOLOGICAL ANATOMY.—The Committee acknowledge the receipt of the following subscriptions:

Dr. J. M. Da Costa, Philadelphia,	$2000
Dr. S. W. Gross, Philadelphia,	1000
Dr. J. Marion Sims, New York,	500
Dr. W. W. Keen, Philadelphia,	100
Dr. J. Ewing Mears, Philadelphia,	100
Dr. Joseph Hearn, Philadelphia,	100
Dr. T. Addis Emmet, New York,	100
